

Eagle Plains Exploration Project
Executive Committee Screening

Revised Project Proposal

Prepared for:

Yukon Environmental and Socio-economic Assessment Board (YESAB)
Whitehorse, Yukon

Version: 1
Date: February 2024

1 Details of the Proposed Project 1-1
1.1 Introduction 1-1
1.2 Project Proponent 1-2
1.3 Project Identification and Description 1-2
1.3.1 Exploration History 1-2
1.4 Project Activities and Components 1-4
1.4.1 Project Activities 1-4
1.4.2 Project Phases 1-9

1.4.3 Project Stages and Schedule 1-9
1.4.4 Project Design Stage 1-32
1.4.5 Proposed Concurrent Activities 1-32
1.4.6 Project Scale 1-35
1.4.7 Access and Transportation 1-35
1.4.8 Workforce and Accommodation 1-40
1.4.9 Project Resource Requirements 1-41
1.4.10 Project Emissions, Discharge of Wastes, and Disturbances 1-43
1.4.11 Third-Party Project Activities 1-49
1.4.12 Project Alternatives 1-50
1.4.13 Proposed Project Benefits 1-53
1.5 Reclamation and Closure 1-54
1.5.1 Seismic Lines 1-55
1.5.2 Mix Bury Cover (MBC) Sump Site Reclamation 1-55
1.5.3 Well Abandonment 1-56
1.5.4 Winter Roads and Winter Well Sites 1-57
1.6 Regulatory Context 1-57
1.6.1 Requirement for an Executive Committee Screening 1-58
1.7 Consideration of Regional Land Use Plans 1-60
1.7.1 Cumulative Effects Indicator Levels 1-64
1.7.2 Conformity with Land Use Plans 1-66
1.8 Effects of the Environment on the Project 1-66
1.8.1 Climate Change and Terrain Instability 1-66
1.8.2 Extreme Weather 1-67
1.8.3 Wildfires 1-68
1.8.4 Fluctuating Surface Water Levels 1-68
1.9 Air and Greenhouse Gas (GHG) Emissions 1-69
1.9.1 Direct Air Emissions 1-69
1.9.2 Fugitive Air Emissions 1-71
1.10 Accidents and Malfunctions 1-72
1.10.1 Vehicular Accidents 1-72
1.10.2 Helicopter Operations 1-72
1.10.3 Mulching Operations 1-73
1.10.4 Seismic Hole Drilling 1-73

1.10.5 Handling, Loading, and Detonating Seismic Explosives 1-74
1.10.6 Releases to the Environment 1-75
1.10.7 Blowouts 1-76
1.10.8 Perforating 1-77
1.10.9 Cementing 1-77
1.10.10 Radioactive Well Logging 1-77
1.10.11 Human-Wildlife Conflicts 1-78
1.10.12 General Safety 1-79

2 Consultation and Engagement 2-1

2.1 Potentially Affected First Nations and Residents of Communities 2-1
2.2 Consultation and Engagement Requirements 2-4
2.3 Consultation and Engagement Principles and Objectives 2-4
2.4 Overview of the Consultation and Engagement Program 2-5
2.4.1 Yearly Summaries of Consultation and Engagement Activities and Events Shaping Involvement in the Program 2-8
2.5 Effects on the consultation and engagement program 2-13
2.5.1 Navigating Collaboration: Consultation and Engagement During the COVID-19 Pandemic and Natural Disasters 2-13
2.5.2 Vuntut Gwitchin Government's *Oil and Gas Engagement Policy* 2-14
2.5.3 Relationship-Building 2-15
2.5.4 Consultation and Engagement Record Management and Legislative Requirements 2-15
2.5.5 Moving Forward: Consultation and Engagement Next Steps 2-16
2.6 Results of Consultation and Engagement 2-16
2.7 Consultation and Engagement with First Nation of Na-Cho Nyäk Dun and Residents of Mayo 2-18
2.7.1 Community Profiles 2-19
2.7.2 Project Notification 2-22
2.7.3 Consultation and Engagement Planning 2-22
2.7.4 Consultation and Engagement Methods 2-22
2.7.5 Consultation and Engagement Activities 2-23
2.7.6 Agreements 2-29
2.7.7 Records Management 2-29
2.7.8 Consultation and Engagement Feedback (Effects, Issues, and Interests) 2-29
2.7.9 Ongoing Consultation and Engagement 2-34
2.8 Consultation and Engagement with Gwich'in Tribal Council, and Residents of Inuvik, Fort McPherson, Tsiigehtchic, and Aklavik 2-34

2.8.1 Community Profiles 2-34
2.8.2 Inuvik 2-38
2.8.3 Project Notification 2-40
2.8.4 Consultation and Engagement Planning 2-40
2.8.5 Consultation and Engagement Methods 2-40
2.8.6 Consultation and Engagement Activities 2-41
2.8.7 Agreements 2-51
2.8.8 Records Management 2-51
2.8.9 Consultation and Engagement Feedback (Effects, Issues, and Interests) 2-51
2.8.10 Ongoing Consultation and Engagement 2-80
2.9 Consultation and Engagement with Vuntut Gwitchin First Nation and Residents of Old Crow 2-80
2.9.1 Community Profiles 2-80
2.9.2 Project Notification 2-83
2.9.3 Consultation and Engagement Planning 2-83
2.9.4 Consultation and Engagement Methods 2-83
2.9.5 Consultation and Engagement Activities 2-84
2.9.6 Agreements 2-95
2.9.7 Records Management 2-95
2.9.8 Engagement Feedback (Effects, Issues, and Interests) 2-95
2.9.9 Ongoing Consultation and Engagement 2-131
2.10 Consultation and Engagement with Tr'ondëk Hwëch'in and residents of Dawson City 2-131
2.10.1 Community Profile 2-131
2.10.2 Project Notification 2-134
2.10.3 Consultation and Engagement Planning 2-134
2.10.4 Consultation and Engagement Methods 2-135
2.10.5 Consultation and Engagement Activities 2-135
2.10.6 Agreements 2-140
2.10.7 Records Management 2-140
2.10.8 Engagement Feedback (Effects, Issues, and Interests) 2-140
2.10.9 Ongoing Consultation and Engagement 2-146
3 Methodology 3-1
3.1 Effects Assessment 3-1
3.1.1 Assessment Scope 3-1
3.1.2 Baseline Conditions 3-10

3.1.3 Exploration Project Planning Context 3-10
3.1.4 Effects Characterization 3-13
3.1.5 Significance Determination 3-18
3.1.6 Cumulative Effects 3-18
3.2 Consideration of Traditional/Indigenous Knowledge 3-25
3.3 Consideration of Aboriginal and Treaty Rights 3-30
4 Permafrost and Terrain 4-1
4.1 Assessment Indicators and Assessment Parameters 4-1
4.2 Project Interactions and Potential Effects 4-1
4.2.1 Interactions Table 4-2
4.2.2 Degradation of Permafrost 4-3
4.2.3 Aggradation of Permafrost 4-4
4.2.4 Terrain Instability 4-4
4.3 Mitigation Measures 4-4
4.3.1 Avoidance of Hazards 4-5
4.3.2 Elimination or Reduction of Hazards 4-5
4.3.3 Accommodation and Management of Hazards 4-6
4.4 Effects Characterization 4-6
4.4.1 Approach 4-6
4.4.2 Residual Effect 4-8
4.5 Significance 4-10
4.6 Cumulative Effects Assessment 4-12
4.6.1 Approach 4-12
4.6.2 Cumulative Effects 4-12
4.6.3 Context and Confidence 4-14
5 Water Resources 5-1
5.1 Existing Surface Water Quality and Hydrology 5-1
5.2 Assessment Indicators and Assessment Parameters 5-2
5.3 Project Interactions and Potential Effects 5-2
5.3.1 Project Interactions 5-2
5.3.2 Increased Sedimentation 5-3
5.3.3 Contaminant and Nutrient Influxes 5-3
5.3.4 Thermal Changes 5-3

5.3.5 Reduced Flow and Water Levels 5-4
5.4 Mitigation Measures 5-4
5.5 Effects Characterization 5-9
5.5.1 Approach 5-9
5.5.2 Increased Sedimentation 5-10
5.5.3 Contaminant and Nutrient Influxes 5-12
5.5.4 Thermal Changes 5-13
5.5.5 Reduced Flows and Water Levels 5-14
5.6 Significance 5-15
5.7 Follow-Up Monitoring 5-16
5.8 Cumulative Effects Assessment 5-16
5.8.1 Cumulative Effects 5-16
6 Fish and Fish Habitat 6-1
6.1 Assessment Indicators and Assessment Parameters 6-1
6.2 Project Interactions and Potential Effects 6-1
6.2.1 Interactions 6-2
6.2.2 Fish Mortality Risk 6-2
6.2.3 Fish Habitat Quality 6-3
6.2.4 Fish Habitat Quantity 6-4
6.3 Mitigation Measures 6-4
6.4 Effects Characterization 6-10
6.4.1 Approach 6-10
6.4.2 Fish Mortality Risk 6-11
6.4.3 Fish Habitat Quality 6-12
6.4.4 Fish Habitat Quantity 6-14
6.5 Significance 6-15
6.6 Cumulative Effects Assessment 6-15
7 Vegetation 7-1
7.1 Assessment Indicators and Assessment Parameters 7-1
7.2 Project Interactions and Potential Effects 7-2
7.2.1 Interactions Table 7-2
7.2.2 Loss or Alteration of Wet Shrub Tamarack Ecosystem 7-3
7.2.3 Loss or Alteration of Ecosystem Units of Conservation Concern 7-3

7.3 Mitigation Measures 7-6
7.4 Effects Characterization 7-8
7.4.1 Approach 7-8
7.4.2 Vegetation Data Limitations 7-11
7.4.3 Residual Loss or Alteration of Wet Shrub Tamarack Ecosystem 7-11
7.4.4 Residual Loss or Alteration of Ecosystems of Conservation Concern 7-13
7.5 Significance 7-15
7.5.1 Significance Criteria 7-15
7.6 Cumulative Effects Assessment 7-16
7.6.1 Approach 7-16
7.6.2 Cumulative Loss or Alteration of Wet Shrub Tamarack Ecosystems 7-16
7.6.3 Cumulative Loss or Alteration of Ecosystems of Conservation Concern 7-18
8 Wildlife and Wildlife Habitat 8-1
8.1 Wildlife Assessment Methods 8-1
8.1.1 Approach 8-1
8.1.2 Wildlife Data Limitations 8-3
8.1.3 Input from Engagement on the Wildlife Assessment 8-4
8.2 Marten 8-4
8.2.1 Assessment Indicators and Parameters 8-5
8.2.2 Project Interactions and Potential Effects 8-5
8.2.3 Mitigation Measures 8-9
8.2.4 Effects Characterization 8-12
8.2.5 Significance 8-16
8.2.6 Cumulative Effects Assessment 8-16
8.3 Moose 8-20
8.3.1 Assessment Indicators and Parameters 8-21
8.3.2 Project Interactions and Potential Effects 8-22
8.3.3 Mitigation Measures 8-24
8.3.4 Effects Characterization 8-26
8.3.5 Significance 8-30
8.3.6 Cumulative Effects Assessment 8-30
8.4 Birds 8-34
8.4.1 Assessment Indicators and Parameters 8-38
8.4.2 Project Interactions and Potential Effects 8-38

8.4.3 Mitigation Measures 8-40
8.4.4 Effects Characterization 8-42
8.4.5 Significance 8-44
8.4.6 Cumulative Effects Assessment 8-44
9 Caribou 9-1
9.1 General Ecology of the Porcupine Caribou Herd 9-1
9.1.1 Subpopulation Size and Trends 9-1
9.1.2 Seasonal Ranges 9-3
9.1.3 Movement Patterns 9-7
9.1.4 Diet and Habitat Selection 9-9
9.2 Porcupine Caribou Management and Conservation 9-11
9.3 Assessment Indicators and Assessment Parameters 9-13
9.4 Project Interactions and Potential Effects 9-14
9.4.1 Interactions 9-14
9.4.2 Direct Habitat Effects 9-16
9.4.3 Indirect Habitat Effect 9-18
9.4.4 Movement Effects 9-20
9.4.5 Direct Mortality Effects 9-24
9.4.6 Indirect Mortality Effects 9-25
9.4.7 Energetics Effects 9-26
9.5 Mitigation Measures 9-27
9.5.1 Avoiding High-Value Habitat 9-29
9.5.2 Clustering of Work in Annual Work Areas 9-29
9.5.3 Access Management 9-29
9.5.4 Seismic Operations 9-30
9.5.5 Construction of Winter Access Roads, Well Sites, and Other Features 9-32
9.5.6 Access Road Use and Maintenance 9-33
9.5.7 Aircraft Operations 9-34
9.5.8 Pre-Work Site Surveys 9-34
9.5.9 Early Warning System for Caribou 9-35
9.5.10 Caribou Interaction Response Plan 9-35
9.5.11 Response to Large Numbers of Caribou 9-37
9.5.12 Worker Training 9-39
9.6 Effects Characterization 9-40

9.6.1 Approach 9-40
9.6.2 Residual Direct Habitat Effects 9-42
9.6.3 Residual Indirect Habitat Effects 9-46
9.6.4 Residual Movement Effects 9-51
9.6.5 Residual Direct Mortality Effects 9-53
9.6.6 Residual Indirect Mortality Effects 9-53
9.6.7 Residual Energetics Effects 9-58
9.7 Significance 9-58
9.8 Follow-up Monitoring 9-59
9.9 Cumulative Effects Assessment 9-61
9.9.1 Approach 9-61
9.9.2 Cumulative Direct Habitat and Movement Effects 9-61
9.9.3 Cumulative Indirect Mortality Effects 9-64
10 Heritage Resources 10-1
10.1 Assessment Indicators and Assessment Parameters 10-1
10.2 Project Interactions and Potential Effects 10-1
10.2.1 Interactions Table 10-1
10.2.2 Disturbance of a Heritage Resources Site 10-2
10.2.3 Disturbance of an Unassessed Area of Potential for Currently Unknown Heritage Resource Sites 10-3
10.3 Mitigation Measures 10-3
10.4 Effects Characterization 10-6
10.4.1 Approach 10-6
10.4.2 Residual Effect 10-7
10.5 Significance 10-8
10.6 Cumulative Effects Assessment 10-8
11 Socio-Economics 11-1
11.1 Methods 11-2
11.1.1 Assessment Boundaries 11-2
11.1.2 Input from Engagement 11-6
11.1.3 Existing Conditions Data 11-7
11.1.4 Effects Assessment 11-10
11.2 Community Infrastructure and Services 11-13
11.2.1 Assessment Indicators and Assessment Parameters 11-13

11.2.2 Project Interactions and Potential Effects 11-13
11.2.3 Mitigation Measures 11-23
11.2.4 Effects Characterization 11-23
11.2.5 Significance 11-25
11.2.6 Follow-up Monitoring 11-25
11.2.7 Cumulative Effects Assessment 11-25
11.3 Land and Resource Use 11-29
11.3.1 Assessment Indicators and Assessment Parameters 11-29
11.4 Community Health and Wellbeing 11-56
11.4.1 Assessment Indicators and Parameters 11-57
11.4.2 Project Interactions and Potential Effects 11-57
11.4.3 Mitigation or Enhancement Measures 11-68
11.4.4 Residual Effects Characterization 11-69
11.4.5 Significance 11-72
11.4.6 Cumulative Effects Assessment 11-73
11.5 Employment and Economy 11-77
11.5.1 Assessment Indicators and Assessment Parameters 11-77
11.5.2 Project Interactions and Potential Effects 11-77
11.5.3 Mitigation or Enhancement Measures 11-87
11.5.4 Residual Effects Assessment 11-89
12 Effects Management 12-1
12.1 Management and Monitoring Plans 12-1
12.1.2 Wildlife Management and Monitoring Plan 12-2
12.1.3 Conceptual Reclamation and Closure Plan 12-2
12.1.4 Health, Safety and Emergency Response Plan 12-2
12.2 Follow Up Monitoring 12-3
13 References 13-1
Section 1 Details of the Project Description 13-1
Section 2 Consultation and Engagement 13-3
Section 3 Methodology 13-8
Section 4 Permafrost and Terrain 13-8
Section 5 Water Resources 13-9
Section 6 Fish and Fish Habitat 13-10

Section 7 Vegetation 13-10
Section 8 Wildlife and Wildlife Habitat 13-11
Section 9 Caribou 13-17
Section 10 Heritage Resources 13-24
Section 11 Socio-Economics 13-25
Section 12 Effects Management 13-28

List of Appendices

Section 1 Details of the Project Description

APPENDIX A. Designated Office Evaluation Report, YESAB, February 9, 2016 A-0

APPENDIX B. Linear Feature Study B-0

Section 2 Consultation and Engagement

APPENDIX 2-A. First Nation of Na-Cho Nyäk Dun and Residents of Mayo Consultation and Engagement Records A-0

APPENDIX 2-B. Gwich'in Tribal Council and Residents of Inuvik, Fort McPherson, Tsiigehtchic, and Aklavik Consultation and Engagement Records B-0

APPENDIX 2-C. Vuntut Gwitchin First Nation and Residents of Old Crow Consultation and Engagement Records C-0

APPENDIX 2-D. Tr'ondëk Hwëch'in and Residents of Dawson City Consultation and Engagement Records D-0

Section 3 Methodology

No appendices.

Section 4 Permafrost and Terrain

APPENDIX A. Terrain and Permafrost Baseline Report A-0

Section 5 Water Resources

APPENDIX A. Surface Water Quality and Hydrology Baseline A-0

Section 6 Fish and Fish Habitat

APPENDIX A. Fish and Fish Habitat Studies A-0

Section 7 Vegetation

APPENDIX A. Ecological and Landscape Classification Mapping A-0

APPENDIX B. Linear Feature Study B-0

Section 8 Wildlife and Wildlife Habitat

APPENDIX A. Wildlife Baseline Studies A-0

APPENDIX B. Linear Feature Study B-0

Section 9 Caribou

Appendix A. Wildlife Baseline Studies A-0

Appendix B. Linear Feature Study B-0

Appendix C. Literature Summary C-0

Section 10 Heritage Resources

APPENDIX A. Heritage Resource Overview Assessment: Eagle Plains Basin Exploration Project A-0

APPENDIX B. Heritage Resource Impact Assessment: Eagle Plains Exploration Project 2023 Interim Report (23-03ASR) B-0

APPENDIX C. Heritage Resource Impact Assessment: Eagle Plains Exploration Project 2022 Final Report (22-22ASR) C-0

Section 11 Socio-Economics

APPENDIX 2-A. Eagle Plains Exploration Project Socio-Economic Baseline Technical Data Report (TDR) A-0

Section 12 Effects Management

No appendices.

Executive Summary

Section 1 Details of the Project Description

The Project Proponent, Chance Oil and Gas Ltd. (Chance) proposes to conduct the Eagle Plains Exploration Project (the Project), an oil and gas exploration program, in north-central Yukon, Canada. This Project proposal is being submitted to the Yukon Environmental and Socio-economic Assessment Board (YESAB) Executive Committee as a comprehensive Revised Project Proposal, to undergo an assessment as part of an Executive Committee Screening process. This is a Referred Project under paragraph 56(1)(d) of the *Yukon Environmental and Socio-economic Assessment Act*, S.C. 2003, c. 7. (Government of Yukon 2003c) (*YESAA*).

The Project is approximately 605 kilometres (km) north of Whitehorse along the Dempster Highway. Chance proposes to conduct exploratory activities over 10 years (2025 to 2034) to confirm the quality, quantity, and areal extent of hydrocarbons. Chance has completed Project-related baseline studies between 2019 and 2023 including surface and groundwater, permafrost, aquatics and fish, vegetation, wildlife, linear features, socio-economic, and heritage resources.

Project activities will focus on the following programs:

- a seismic exploration program;
- an exploratory drilling program; and,
- an extended flow testing (EFT) program at select wells.

The seismic program will require up to 1,500 square kilometres (km²) of 3D Low Impact Seismic (LIS) data acquisition (2.75 metres [m] wide source lines and 1.75 m wide receiver lines) and up to 2,000 km of 2D seismic (2.75 m wide). LIS will provide high-quality information about the geology of Eagle Plains while minimizing environmental effects compared to historic approaches to seismic testing. The seismic program will include seismic line construction, recording and data analyses to understand the area's complex geology. The line preparation (access road construction, line cutting and mulching, surveying, and drilling) and the establishment of temporary creek crossings will be conducted during the winter months under frozen ground conditions. Seismic recording would then follow in the summer months with a wireless system including helicopter use for deployment and recovery of recording equipment and data collection.

The exploratory drilling program consists of up to seven wells drilled sequentially (one to two wells at a time) per year, to a maximum of 30 wells over the 10-year term of the Project. The number and sequence in which wells are drilled depends on previous drilling success, extended flow test (EFT) results, data collected from the seismic exploration program, weather, and road conditions. The drilling program will require winter access roads, including a combination of new access roads (i.e., previously uncleared or used more than 10 years ago) and previously cleared access roads. Temporary drilling pads will only exist during winter and will be created from snow on areas cleared of trees and tall vegetation; the ground will remain mostly undisturbed.

If an exploration well is successful (i.e., the discovery of crude oil or natural gas in sufficient quantities), an EFT will be conducted at that well, to an estimated maximum of 30 wells. An EFT at an individual well could

last for several months up to the end of winter, depending on the well and whether the discovery is principally crude oil or natural gas. The EFT program will be staggered across the Project wells.

Progressive reclamation and closure activities are planned to be ongoing during the exploration program. This includes the reclamation of winter roads, abandoned well pads, seismic lines, and clearings due to accessory activities. As this Project primarily involves winter activities (except for seismic recording), reclamation will mostly rely on low impact seismic, stem bending, and natural regeneration, intended to minimize ground surface disturbance. All unsuccessful wells will be appropriately abandoned in accordance with regulatory requirements, reclaimed progressively, and monitored to assess the progress of revegetation and recovery following the completion of work in an area. At the end of the Project, the MBC sump area will be decommissioned and reclaimed, and all active wells that have successfully undergone EFT will be appropriately suspended pending potential future development approval.

The Project includes development of new infrastructure and will utilize existing infrastructure. Construction of a central processing facility (CPF) adjacent to the camp, will allow Chance to store, further treat/separate fluid produced during EFT and transfer it to trucks for disposal. An airstrip approximately 1,500 m long will be constructed at about km 4 along the Chance winter road from the Dempster Highway intersection. The airstrip will be used only during the winter throughout the Project life. The existing camp (Chance Camp), office, and storage yard were established in October 2011 during previous exploration activities in the Eagle Plains basin and are located at km 325 of the Dempster Highway. The existing 75-person camp will house workers and be a central location during all Project components. Due to the remoteness of seismic activities, a remote camp (fly-in) will be established near the proposed East Greaves and West Greaves Winter Roads, roughly 40 km from the Chance Camp, to accommodate approximately 25 personnel. In addition, a small mobile camp will be established at each active well for onsite accommodation for three personnel.

Sources of waste at the Project include domestic and sewage waste at the camps, and drilling waste at the well sites. The main waste discharge from the Project is anticipated to be drilling waste produced at the well sites. Waste management consists of an incinerator for burning non-toxic and food waste and a secure storage area for other forms of waste. Wastewater disposal at the Chance Camp consists of a wastewater treatment plant, a holding lagoon, and an exfiltration system. For other remote and mobile camps, wastewater and sewage will be collected in tanks approved by the CSA and transported off site for disposal at an approved facility. At each well site during drilling, there will be sewage storage, and a food waste incinerator related to the operation of the related camp accommodation. Drill cuttings will be disposed of into a series of mix-bury-and-cover (MBC) pods within a single MBC sump area. Formation water, saline fluids, drilling fluids and rig wash will be disposed of underground in approved deep-injection wells converted from existing suspended wells.

The Project may use of up to 300 m^3 of water per day (or per permitted limits) for camp use and for making ice as part of building winter roads, ice roads and temporary well sites, not exceeding 10% of the instantaneous flow from approved extraction points including Eagle River, Ogilvie River, Whitestone River and Glacier Creek. Water sources and volumes will follow issued water permits. Bottled water will be provided for human consumption.

Third-party activities and contractor/subcontractor support that are anticipated for the Project may include, contractors, subcontractors, supply services and vendors, as needed.

The Project is located within the North Yukon Planning Region and Peel Watershed Planning Region and is therefore subject to the approved *North Yukon Regional Land Use Plan* (NYRLUP) (Vuntut Gwitchin Government and Yukon Government 2009) and the *Peel Watershed Regional Land Use Plan* (PWRLUP) (Peel Watershed Planning Commission 2019). Within both plans, the Project is within a designated Zone IV integrated management area which allows for the highest development level to occur, in comparison to Zone I through Zone III integrated management areas which are classified as having higher sensitivity to landscape disturbance, ecological and cultural values, risk of significant adverse effects, and level of acceptable change.

Some proposed Project benefits related to employment, training and contracting for services and goods for Yukon First Nations, its citizens, residents of communities affected by the oil and gas activity, and other Yukon residents are possible. Should the exploration Project be successful, the benefits may expand to accommodate investment interest in infrastructure associated with a potential future development, if approved. Chance is committed to ongoing engagement with First Nations about the Project and ongoing consultation and discussions around potential Project benefits and associated Benefits Agreements, following Section 68 of the *Yukon Oil and Gas Act*, RSY 2002, C.162 (Government of Yukon 2002h) *(YOGA)* including training, employment, and contracting opportunities with potentially affected First Nations.

Section 2 Consultation and Engagement

As per the Y*ukon Environmental and Socio-economic Act, SC 2003, c 7 (YESAA*) requirements, Chance has undertaken consultation and engagement activities with potentially affected First Nations and residents of communities. **Section 2 Consultation and Engagement** describes Chance's First Nations Consultation and Engagement Program (the Program) including:

- information about potentially affected First Nations and residents of communities;
- consultation and engagement requirements for the Project;
- consultation and engagement principles and objectives;
- consultation and engagement with potentially affected First Nations and residents of communities during challenges to the Program, including COVID-19 and natural disasters; and,
- consultation and engagement activities with potentially affected First Nations and residents of communities from 2014 to December 20, 2023.

Potentially affected First Nations and residents of communities consulted and engaged about the Project include (alphabetically):

- First Nation of Na-Cho Nyäk Dun;
- Gwich'in Tribal Council, comprising:
  - Ehdiitat Gwich'in Council;
  - Gwichya Gwich'in Council (Tsiigehtchic);
  - Nihtat Gwich'in Council; and,
  - Tetl'it Gwich'in Council.
- Tr'ondëk Hwëch'in;
- Vuntut Gwitchin First Nation; and,
- Residents of Aklavik, Dawson City, Fort McPherson, Inuvik, Mayo, Old Crow, and Tsiigehtchic.

Chance's engagement with potentially affected First Nations and residents of communities has and continues to be focused on meeting the following *YESAA* requirements:

- providing opportunities to share Project information, including information on potential Project-related effects to support potentially affected First Nations and residents of communities to prepare and present views about the Project; and,
- considering, fully and fairly, views presented by potentially affected First Nations and residents of communities about the Project.

Chance has undertaken consultation and engagement activities with potentially affected First Nations and residents of communities since 2014. During this time, Chance sought to solicit views, concerns, input, and feedback about the Project; however, some events hindered active consultation and engagement activities between Chance, and potentially affected First Nations and residents of communities.

Chance recognizes that First Nation governments and communities have faced capacity challenges and time and resource constraints required to participate meaningfully in the Program. Chance acknowledges the importance of First Nations governments and communities having opportunities to provide feedback and be heard on their concerns related to the Project. Chance is committed to an engagement process that seeks to align with First Nation expectations, *YESAA* and related guidance, and best practices.

In January 2023, Chance reinitiated consultation and engagement activities with potentially affected First Nations. Chance sought to establish positive and collaborative relationships that would continue through the YESAB EC screening assessment process and into future Project phases, if approved. Consultation and engagement activities between 2014 and 2023 included ongoing Project communications and updates via email, phone call, and text message, community open house events, virtual and in-person meetings, and document sharing. Chance shared an updated Draft Project Description with potentially affected First Nations in July 2023. Consultation and engagement activities since July 2023 have focused on developing a shared understanding of the Project; specifically, how the Project design has changed in response to First Nation and resident of communities' feedback from 2014 to 2023. Chance provided opportunities to discuss and share information about the Project, Project-related effects, and mitigation measures with potentially affected First Nations and residents of communities. Chance also created opportunities for Chance, potentially affected First Nations, YESAB's EC, and Government of Yukon to meet collectively to develop a shared understanding of the screening process and discuss opportunities to support potentially affected First Nations' involvement in the Project's assessment process. Feedback shared by potentially affected First Nations and residents of communities, and how Chance has responded and adapted the Project to feedback shared, is outlined in this Project Proposal.

Chance recognizes that additional challenges may affect its ability to consult and engage in the most effective way with potentially affected First Nations and residents of communities. However, Chance is committed to continuing to work with, and to have open dialogue with, potentially affected First Nations and communities throughout all stages of the Project. This includes providing information, giving sufficient time for review and consideration, accepting feedback, and taking input into consideration. Additionally, Chance will follow consultation and engagement guidelines and protocols established by potentially affected First Nations, Government of Yukon, and the *YESAA*.

Section 3 Methodology

Section 3 Methods outlines the approach followed for assessing the effects of the Project on Environmental and Socio-Economic values. The Project effects assessment methods follow guidance provided by Yukon Environmental and Socio-economic Assessment Board (YESAB) in YESAB's Environmental and Socio-Economic Assessment Methodology (YESAB 2021a).

Eleven VESECs were identified for the Project assessment:

Environmental:

- Permafrost and Terrain;
- Water Resources;
- Fish and Fish Habitat;
- Vegetation;
- Wildlife and Wildlife Habitat; and,
- Caribou.

Socio-economic:

- Heritage Resources;
- Community Infrastructure and Services;
- Land and Resource Use;
- Community Health and Wellbeing; and,
- Employment and Economy.

To quantify or qualify the potential effects of the Project on each of the VESECs, one or more indicators and one or more assessment parameters were defined for each of these VESECs. Spatial boundaries, defined as the areas within which the effects of the Project are expected to interact with the VESECs and indicators, were defined for each VESEC. Project temporal boundaries looked at the 10-year life of the Project as a single Exploration phase, during which all Project activities are expected to occur somewhat concurrently (Project infrastructure/well development, drilling, extended flow testing).

Baseline studies were conducted on all VESECs to support characterizing existing conditions, against which potential effects of the Project were evaluated. Project potential effects were assessed using a combination of quantitative and qualitative information on Project design and activities.

Some Project footprints, including well sites, well access roads, and secondary camp locations were not spatially-defined because the locations of many of these sites depends on the early findings from the drilling and seismic programs. Given this uncertainty in some Project Footprints, and to assist with quantifying the effects of the Project, ten well site scenario models were developed to evaluate a range of potential Project effects on the environment.

Environmental constraints mapping, developed for the Project, was used as part of the scenario modeling, and was further integrated into VESEC-specific mitigations during the relevant effects assessments. This, along with a series of targeted mitigation measures, are proposed for mitigating the potential effects of the Project on the environment. These mitigations were taken into consideration when characterizing predicted

residual effects. Where the magnitude of residual effects was characterized as low or greater, an assessment of cumulative effects was also conducted.

Section 4 Permafrost and Terrain

Section 4 Permafrost and Terrain outlines the assessment of Project effects on this Valued Environmental and Socio-Economic Component (VESEC). The Project has the potential to interact with permafrost and terrain stability, and the indicators for assessing potential adverse effects were changes to the extent of ground ice and changes that results in ground settlement or mass movement. The assessment approach for permafrost was a quantitative approach to permafrost degradation, or aggradation. The assessment approach to terrain stability was a qualitative discussion on terrain instability.

A baseline study was undertaken which detailed the current permafrost and terrain stability conditions within the Regional Study Area (RSA); the Exploration Development Suitability (EDS) assessment outlined in **Appendix 4-A Terrain and Permafrost Baseline Report** is an important component of the environmental constraints map used for the Project.

Results of the assessment for permafrost and terrain state that with the implementation of proposed mitigation measures there should be a low magnitude change to permafrost and terrain stability over a localized area, although the results are generally considered irreversible. The residual effects of the Project on permafrost and terrain stability are rated as **not significant.**

Section 5 Water Resources

Section 5 Water Resources considers potential effects of the Project on surface water quality and hydrology due to the potential for these types of effects to further directly or indirectly affect aquatic ecosystems and the fish, aquatic organisms, wildlife, and humans that utilize and are supported by these aquatic ecosystems.

Existing surface water quality and hydrology conditions in the Regional Study Area (RSA) were characterized through baseline studies and analysis of data collected between 2013 and 2020. Baseline studies found that the RSA contains a high number of streams (approximately 1,467, which are mainly smaller headwater streams), and relatively few waterbodies (none of which are greater than 5 hectares [ha]). Watercourses in active permafrost regions, like that of the RSA, range from permanent flow to intermittent flow, which are seasonally timed. The lower order streams are more likely to be seasonally intermittent as inputs from precipitation decrease as rain transitions to snow, and baseflows are reduced as shallow permafrost re-freezes. In the case of the smaller streams, the channel may fully freeze in early winter. Additionally, ice build-up in watercourses alters flow behaviour through the formation of ice in the channel as well as changes to flow dynamics in flowing streams of all sizes, with this effect occurring naturally from the beginning of freeze-up until spring thaw is complete.

The direct and indirect pathways for potential effects of the Project on water resources are through sedimentation, contaminant and nutrient influxes, thermal changes and reduced flow and water levels. With the implementation of mitigation, residual effects due to sedimentation, contaminant and nutrient influxes,

and thermal changes are predicted to be negligible. Low magnitude effects are predicted for flows and water levels as a result of water withdrawals for Project activities, but these withdrawals will be managed within the limits set by approved water licences/permits, be supported by a proposed flow monitoring program, mainly occur during the winter when fish are typically absent from the RSA, and are reversible once water withdrawals cease. Residual effects on water resources are predicted to be **not significant.**

Section 6 Fish and Fish Habitat

The assessment in **Section 6 Fish and Fish Habitat** examined Project interactions with fish their habitats, focusing on two assessment indicators: fish mortality and fish habitat. Projects effects were evaluated against these two indicators through a qualitative evaluation of change to fish mortality risk, and a qualitative evaluation of changes in fish habitat quality and quantity, using data from baseline studies conducted for the Project.

The Regional Study Area (RSA) encompasses 1,467 mapped streams, most of which are smaller headwater streams. Few ponds and lakes occur in the RSA and none are greater than 5 hectares (ha) in size. During the winter, when the majority of Project activities will occur, fish are generally not present in the RSA. Smaller streams fully freeze or dewater, whereas larger streams have residual pools with no flow and associated low dissolved oxygen. Most fish are suspected to migrate out of the study area to larger rivers for overwintering.

With the implementation of all proposed mitigation measures, negligible residual effects are predicted for change in mortality risk, change in fish habitat quality, and change in fish habitat quantity.

Section 7 Vegetation

An assessment of Project effects on Vegetation (**Section 7**) was conducted, with a focus on two indicators: wet shrub tamarack-producing ecosystem units and ecosystem units of conservation concern. Ecosystem units of conservation concern were identified as the following: dry ecosystem units, riparian spruce sites and unique wetland sites. The assessment primarily consists of a quantitative assessment of the change in area for each of the two indicators.

Baseline studies were conducted to support the assessment and included ecosystem mapping and database development, field sampling and surveys within the Regional Study Area (RSA). Field surveys completed by EDI documented 125 different plant species, including trees, shrubs, and forbs, ferns and allies, graminoids, lichens, moss, and liverwort species throughout the RSA. In addition to these individual vegetation species, thirty-one distinct ecosystem units were mapped within the RSA. Most of the RSA is mapped in a shrub structural stage and is dominated by moist and mesic black and white spruce forests, with Labrador tea (Rhododendron groenlandicum), alder (Alnus spp.) and birch (Betula spp.) shrub cover.

For wet shrub Tamarack-producing ecosystem units, a low magnitude residual effect is predicted to last for the long-term, but be reversible, once trees and tall shrubs regenerate following cessation of Project activities. For ecosystems of conservation concern, a low magnitude residual effect is predicted to last for the long-term but be reversible once trees and tall shrubs regenerate. The predicted residual effects of the

Project on the vegetation Valued Environmental and Socio-Economic Component (VESEC) are not expected to result in a change in ecosystem units within the RSA to the point where they are no longer regionally viable or persistent. Therefore, with the implementation of all proposed mitigation measures, the residual effect on vegetation is predicted to be **not significant.**

Section 8 Wildlife and Wildlife Habitat

Section 8 Wildlife and Wildlife Habitat summarizes the assessment of Project effects on marten, moose and birds. The assessment primarily examined how changes in available habitat could affect marten, moose, and birds, and how changes in mortality risk could affect marten and moose using data from baseline studies.

Baseline studies were conducted to support the assessment. Baseline studies included field surveys, habitat modeling, and a desktop review of wildlife species that are of conservation or management concern which could occur in the RSA. The Project overlaps with boreal taiga and is characterized by open-canopy, spruce-dominated habitats where permafrost generally limits tree growth, with limited anthropogenic disturbance of wildlife habitat. Surveys confirmed the presence of five bird species of conservation concern and identified extensive low-suitability marten and moderate-suitability moose habitat.

The Project's footprints and activities may result in low magnitude, adverse residual effects that will not have a significant effect on wildlife. Changes in habitat for marten, moose, and birds and an increase in mortality risk for marten and moose are predicted to occur; however, mitigation measures are anticipated to be effective at minimizing adverse effects

Section 9 Caribou

The Project occurs exclusively within the Porcupine Caribou Herd (PCH) range. The PCH is a subpopulation of barren-ground caribou (Rangifer tarandus groenlandicus) known for its widespread distribution, large population aggregations, dramatic fluctuations in population size, and lengthy seasonal migrations (COSEWIC 2016). Within the North Yukon Regional Land Use Plan, the PCH is considered “the most significant and culturally important wildlife resource in the planning region” (Vuntut Gwitchin Government and Yukon Government 2009). Section 9 Caribou presents the assessment of Project effects on this VESEC, which was selected based on the cultural, ecological, and economic value of caribou to First Nations and the Yukon.

Although most barren-ground caribou subpopulations are in decline (COSEWIC 2016), the PCH has increased in size over the last two decades. After 50 years of PCH monitoring, the subpopulation has not exhibited fluctuations in size as large as other barren-ground caribou subpopulations (COSEWIC 2016). This may be due to the PCH’s large annual and seasonal ranges and the diversity of habitats across these ranges (Russell et al. 1993, Whitten 1996).

The Porcupine Caribou Technical Committee (1993) assessed the relative importance of seasonal ranges using six criteria: energy balance, reproductive contribution, tolerance to disturbance, escape requirements, intensity of use, and whether alternative habitats are available. Although all seasons are important to

meeting the annual life requisites of the PCH, the calving and post-calving seasons are considered of the highest importance, and fall and winter are considered of the lowest importance (Porcupine Caribou Technical Committee 1993).

The PCH has historically overlapped the Project Regional Study Area (RSA) in the rut/ late fall and winter periods. However, the RSA overlaps a small portion of those seasonal ranges—6.0 percent (%) during rut/ late fall and 6.5% during winter—and does not overlap with the most frequently used portions of those ranges. Baseline data suggests that Porcupine caribou typically make movements of several kilometres per day in both rut/ late fall and winter and rarely spend multiple days in the same location. Residency times are shorter during rut/ late fall than winter and shorter in the RSA compared to the broader seasonal ranges. The combination of faster daily movements and shorter residency times in the RSA to the broader seasonal ranges suggests the PCH's historical transient use of the RSA.

The Project's PCH baseline studies involved quantifying habitat selection during rut/ late fall and winter. Selected habitat, especially areas of High quality, were mostly dependent on the amount and distribution of light macrolichen cover. During winter lichens constitute the primary forage of most barren-ground caribou populations (COSEWIC 2016).

Based on the PCH's ecology and possible interaction with the Project RSA the Project has the potential to affect PCH habitat, movement, mortality, and energetics. Key factors considered when determining Project interactions and potential effects include temporal overlap, spatial extent, caribou movement rates, and land use planning context. Overlap between the Project and PCH will likely occur during the herd's rut/ late fall and winter seasons (October to April, annually) when the herd is present in Eagle Plains. However, rut/ late fall and winter are considered the seasons of lowest concern. During rut/ late fall and winter, caribou are typically in prime body condition, experience neutral to positive energy balances, do not experience stress from heat and insect harassment, and are least sensitive to human disturbances. Furthermore, the Project RSA (2,400 km²) is a relatively small portion of the PCH's rut/ late fall and winter ranges in Yukon.

During rut/ late fall and winter, the PCH is typically widely dispersed in small and medium-sized groups (Russell et al. 1993). In any given year, Project activities will be clustered to annual work areas so that disturbances are limited to approximately a third (32%) of the RSA, reducing the degree of overlap with the PCH rut/ late fall and winter ranges to about 2% of their total extent in Yukon. The 2% area of overlap could correspond to 2,180 caribou with the potential to interact with the Project. For caribou that might use the RSA, their residency would likely last only a small portion of the rut/ late fall and winter seasons. Overall, the relatively small spatial and temporal overlap between the Project and PCH would be expected to limit the exposure of individual caribou to Project-related disturbances.

The Project is expected to have direct habitat effects on caribou via vegetation clearing associated with the development of seismic lines, winter access roads, well sites, and secondary camps. Vegetation clearing is expected to reduce the amount of 'selected' (moderate and high quality) habitats by caribou. The extent of direct habitat effects on rut/late fall and winter habitat are 0.2% in Eagle Plains (Ecoregion) and up to 2% in the RSA (Region), translating to a negligible magnitude effect.

Indirect habitat effects refer to reduced use of 'selected' (moderate and high quality) habitats by caribou due to sensory disturbances from adjacent areas (also referred to as reduced habitat effectiveness). Several Project activities, including winter access road construction and operation, seismic exploration, well development and operation, and camp operations, can potentially cause indirect habitat effects. The

magnitude of indirect habitat effects on the PCH is predicted to be low to moderate depending on the scale at which they are assessed. The annual work areas are small relative to the rut/ late fall and winter season ranges, so a relatively small proportion of the population is likely to be affected. The residency time of caribou occurring in annual work areas is expected to be short (e.g., 1–2 weeks during winter), and caribou will have alternative habitat available to them outside annual work areas. The energetic cost for affected animals to use alternative habitat is expected to be relatively low because PCH caribou are typically in good body condition in fall and winter and usually travel several kilometres per day during these seasons.

The Project can potentially affect caribou movements by creating sensory disturbances (e.g., noise) that result in avoidance of those areas by caribou. The magnitude of residual effects on caribou movements depends on the scale of analysis, ranging from low to moderate magnitude. Most caribou travelling through the rut/ late fall and winter ranges will not be exposed to the Project; based on the relatively small size of annual work areas compared to PCH rut/ late fall and winter seasonal ranges (≤1% of the seasonal ranges by area), a relatively small proportion of the PCH population is likely to be exposed to Project activities that could affect movement. For caribou that do travel through or around the annual work area, the most likely effects are elevated energetic output or stress; any effects on movement that do occur are expected to be limited to local alterations to the location and timing/rate of movement within the RSA which, if they occur, could cause indirect effects on individual animals such as stress or increased energy expenditures, but are unlikely to impede broad movements among seasonal ranges.

The Project can potentially cause indirect mortality to caribou by creating linear features that can enhance access and hunting efficiency of humans and wolves (facilitated predation). If indirect mortality were to result from the Project, the magnitude and duration of effects would likely be limited to the annual work areas in the years they were active, specifically when Project activities result in snow packing along linear features. Depending on the scale at which effects are evaluated, and in consideration of the complexity of factors involved, the magnitude of effects due to indirect mortality is predicted to be negligible to moderate, and would translate to a minimal population-level effect.

The Project is not expected to substantially affect caribou habitat, movement, mortality, or energetics. The collective residual effects on caribou from all potential sources are assessed to be **not significant.**

Section 10 Heritage Resources

Section 10 Heritage Resources outlines the assessment of Project effects on this Valued Environmental and Socio-Economic Component (VESEC). Heritage Resources include archaeological, historic, and palaeontological resources, and were selected as a VESEC for the Project because of their cultural importance. Indicators related to Heritage Resources include known Heritage Resource sites, identified areas of potential for currently undocumented Heritage Resource sites within the Regional Study Area (RSA), and chance finds of Heritage Resources in areas not associated with known sites or identified areas of potential for currently undocumented archaeological and historic sites. These indicators were selected to support protection of known sites and areas of potential for undocumented sites from being adversely affected by Project activities, to comply with the cultural values of people who utilize the RSA, and to adhere to applicable legislation. The assessment parameter used to evaluate effects on Heritage Resources is

whether or not the Project will cause a qualitative change to the nature or condition of each of the three indicators.

A Heritage Resource Overview Assessment (HROA) covering the RSA was completed in 2022 to establish the initial baseline conditions with regard to Heritage Resources by identifying all known Heritage Resources within the RSA and developing a model mapping areas of high potential for currently unknown Heritage Resource sites. Heritage Resource Impact Assessments have also been completed in the Project area between 2000 and 2023 to ground truth areas of potential concern and, more recently, to test HROA model mapping predictions.

Results of this assessment state if the mitigation measures as described are followed, there should be negligible adverse residual effects resulting from the Project. In consideration of the mitigation that has been implemented to date, and the mitigation that will be implemented as the Project moves forward, the residual effects of the Project on Heritage Resources for all phases of the Project are rated not significant.

Section 11 Socio-Economics

Section 11 Socio-Economics describes and summarizes the assessment of potential effects of the Project on the human environment related to social, economic, health, and cultural conditions. Four Valued Environmental and Socio-Economic Components (VESECs) were identified as part of the Socio-Economic assessment:

- Community Infrastructure and Services: assesses the Project effects on community related infrastructure and services;
- Land and Resource Use: assesses the Project effects to commercial, recreation, and traditional land and resource use;
- Community Health and Wellbeing: assesses the Project effects on the health and wellbeing of the communities in the vicinity of the Project; and
- Employment and Economy: assesses the Project effects to labour, goods and services, employment and business opportunities, and the regional or local economy.

A desktop review was conducted to gather information on existing demographic and socio-economic conditions. Primary data collection through interviews with key informants was then undertaken to confirm the findings from secondary data collection and to address identified data gaps related to socio-economic conditions in the Local Study Area (LSA) and Regional Study Area (RSA). Where possible, collected data were disaggregated to capture information about the conditions of different sub-groups within the population of the LSA and RSA.

For community health and wellbeing, a report assessing the environmental determinants of health for the Project was completed in November 2023 that assessed the potential effects of Project activities on the environmental determinants of health for human receptors in the LSA. The assessment evaluated whether any Project activities present a complete risk pathway for exposure, consisting of an identified hazard, a pathway of exposure and a human that would be exposed. The evaluation considered the seasonality of Project activities as well as varying harvesting seasons that affect land users time on the land.

Project effects on community infrastructure and services were assessed by taking into consideration changes in the demand for housing and temporary accommodation, physical infrastructure, social services, and in the use of transportation infrastructure from existing conditions. No or negligible effects were predicted for most community infrastructure and services indicators. The Project is expected to result in a low magnitude effect on the use of transportation infrastructure from increased traffic. Project-related vehicles have the potential to result in a minor increase in traffic that would be potentially distinguished within the existing volume of traffic along the Dempster Highway and portions of the North Klondike Highway. This effect on community infrastructure and services is expected to be **not significant**.

Project effects on land and resource use were assessed by taking into consideration potential changes in commercial and recreational land and resource use, and First Nations culture and land and resource use. No or negligible effects were predicted for existing designated lands, availability, and abundance of resources for commercial use, land area and access for commercial and recreational use, and resource availability, abundance or quality for subsistence use. The Project is expected to result in low magnitude changes in environmental conditions for recreational use, low magnitude effects to land area and access for First Nations cultural use, and low magnitude effects to environmental conditions for First Nations cultural use. These effects on land and resource use are predicted to be **not significant.**

Project effects on community health and wellbeing were assessed by taking into consideration potential changes in environmental quality that may affect human health, and potential changes to social determinants of health. Negligible effects were predicted for human health associated with changes to drinking water quality, air quality, and traditional food quality. Negligible effects were also predicted for access to healthcare services and infectious disease rates. The Project is expected to result in a low to moderate magnitude change in substance use, and a low to moderate magnitude change in human health to a small proportion of First Nation land users. These effects on community health and wellbeing are predicted to be **significant**.

Project effects on employment and economy were assessed by taking into consideration the potential effects on local and regional employment opportunities, local and regional business opportunities, potential effects on economic diversity, and potential effects on territorial and local government finances. The Project is expected to result in a positive effect on both the employment opportunities and business opportunities at local and regional scales, and a positive effect on economic diversity. No effect was predicted on territorial and local government finances.

Section 12 Effects Management

Management and monitoring plans and associated subplans will be developed for the Project as required, and will include safety, prevention, mitigation, management, and monitoring measures where appropriate. Developed plans may include the following:

- Environmental Management Plan;
- Wildlife Management and Monitoring Plan;
- Conceptual Reclamation and Closure Plan;
- Safety Management and Emergency Response Plan; and,
- Consultation and Engagement Plan.

The plans are required as part of Project design and all Project activities, and will consider potential environmental and socio-economic effects, effectiveness of applied mitigation measures, and will include adaptive management measures and associated follow-up monitoring requirements.

Acknowledgements

Chance Oil and Gas Ltd. (Chance) would like to acknowledge that the Project falls mostly within the Traditional Territory of the Vuntut Gwitchin First Nation, overlaps small areas of the Traditional Territories of the First Nation of Na-Cho Nyäk Dun and Tetłʼit Gwichʼin Council, and is adjacent to the Tr'ondëk Hwëch'inʼs Traditional Territory.

During the preparation of this Revised Project Proposal, Chance sought to solicit views, concerns, input, and feedback about the Project from many individuals and communities. Chance would like to thank the following First Nations and their members for their contributions and feedback during consultation and engagement activities (listed alphabetically):

- First Nation of Na-Cho Nyäk Dun;
- Gwichʼin Tribal Council, comprising:
- Ehdiitat Gwichʼin Council;
- Gwichya Gwich'in Council (Tsiigehtchic);
- Nihtat Gwichʼin Council; and,
- Tetłʼit Gwichʼin Council.
- Tr'ondëk Hwëch'in; and,
- Vuntut Gwitchin First Nation.

Chance would also like to thank the residents of the following communities for their contributions and feedback during consultation and engagement activities for the Revised Project Proposal (listed alphabetically):

- Aklavik;
- Dawson City;
- Fort McPherson;
- Inuvik;
- Mayo;
- Old Crow; and,
- Tsiigehtchic.

Chance is submitting this Revised Project Proposal for review to the Yukon Environmental and Socio-economic Boardʼs (YESAB) Executive Committee (EC) for a screening. Chance thanks the members of YESAB and the EC for their support, feedback and guidance during the development and submission of the Revised Project Proposal.

Chance recognizes that a variety of other territorial and federal regulatory agencies and Decision Bodies are involved in the review of the Project and associated submissions for Project authorizations and wishes to thank representatives of the Yukon Government and Government of Canada for their input, and the members of the Yukon Land Use Planning Council for reviewing the Revised Project Proposal as part of the land use plan conformity check.

1 DETAILS OF THE PROPOSED PROJECT

1.1 INTRODUCTION

The Eagle Plains Exploration Project proposal is being submitted to the Yukon Environmental and Socio-economic Assessment Board (YESAB) as a comprehensive Revised Project Proposal to the Executive Committee, to undergo an assessment as part of an Executive Committee Screening process, as described in **Section 1.6.1 Requirement for an Executive Committee Screening**. As this is a Referred Project under paragraph 56(1)(d) of the *Yukon Environmental and Socio-economic Assessment Act*, S.C. 2003, c. 7. (Government of Yukon 2003c) (*YESAA*), the Pre-Submission Engagement process under YESAB does not occur, and therefore no separate Project Description was provided, and no Project Proposal Report will be issued by YESAB before Project Proposal submission. Based on this process, this Revised Project Proposal report (hereafter referred to as the Project Proposal) presents the anticipated required information for the Project including:

1. Details of the Proposed Project;
2. Consultation and Engagement;
3. Methods;
4. Permafrost and Terrain;
5. Water Resources;
6. Fish and Fish Habitat;
7. Vegetation;
8. Wildlife and Wildlife Habitat:
    - 8.1 Marten;
    - 8.2 Moose; and,
    - 8.3 Birds.
9. Caribou;
10. Historic Resources;
11. Socio-Economics:
    - 11.1 Community Infrastructure and Services;
    - 11.2 Land and Resource Use;
    - 11.3 Community Health and Well-being; and,
    - 11.4 Employment and Economy.
12. Effects Management:
    - 12.1 Management and Monitoring Plans; and,
    - 12.2 Follow Up Monitoring.

Relevant maps and appendices are attached as supporting documentation.

1.2 PROJECT PROPONENT

The Project Proponent is Chance Oil and Gas Ltd. (Chance). The Chance Whitehorse office is located at:

208 Main Street, Suite 202

Whitehorse, YT, Canada Y1A 2A9

The contact for the Chance Project is:

Greg Charlie, Vice President and Community Relations

Chance Oil and Gas Limited

Email: gcharlie@chanceyukon.ca

Tel: 867 456 7805

The former proponent of the Project was Northern Cross (Yukon) Limited. In 2016, a subsidiary of CNOOC Ltd., which held majority ownership of Northern Cross (Yukon) Limited shares, sold all its holdings to existing and new company shareholders. This restored the company's status to that of a Canadian-controlled private company, though the legal entity did not change. The change in ownership resulted in the company's name to Chance Oil and Gas Limited (Chance) in 2017.

1.3 PROJECT IDENTIFICATION AND DESCRIPTION

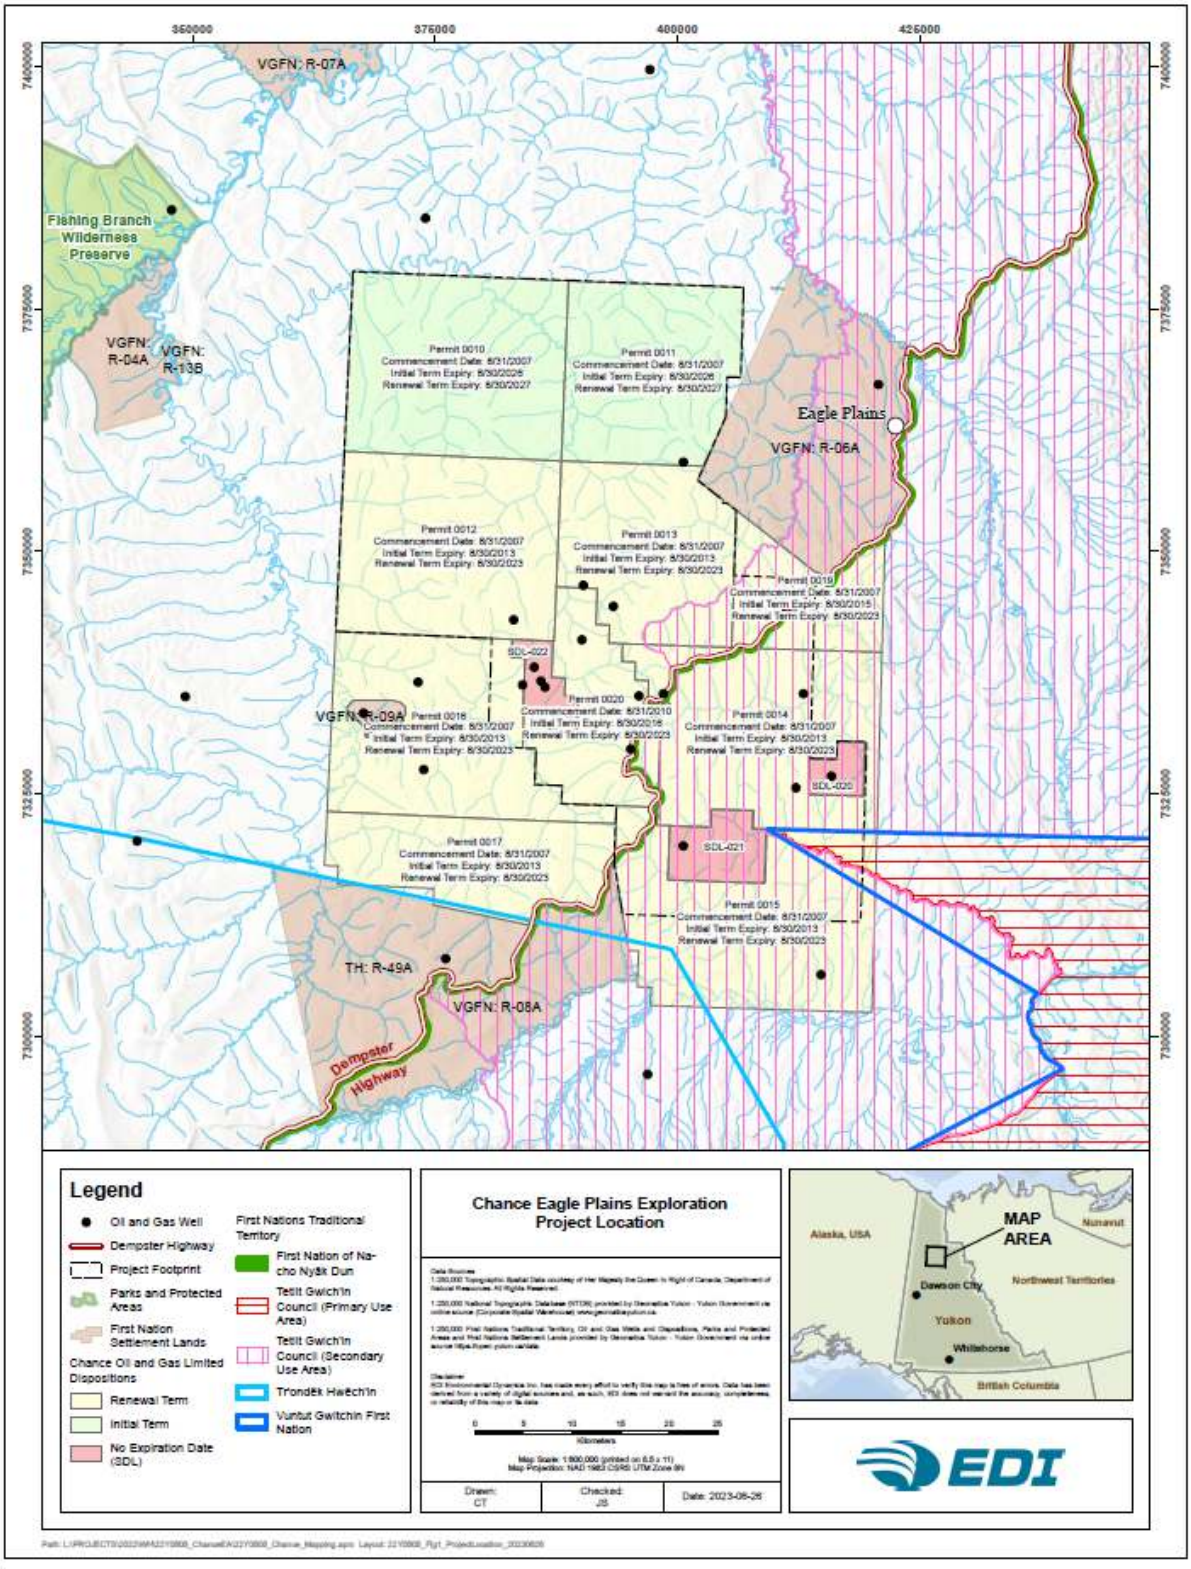
Chance proposes to conduct the Eagle Plains Exploration Project (the Project), an oil and gas exploration program, in north-central Yukon, Canada. The Project is approximately 605 kilometres (km) north of Whitehorse along the Dempster Highway (**Map 1-1**). Chance proposes to conduct exploratory activities over 10 years (2025 to 2034) to confirm the quality, quantity, and areal extent of hydrocarbons.

1.3.1 Exploration History

The Project occurs within the Eagle Plains sedimentary basin, north of the Ogilvie River and west of the Richardson Mountains. The basin contains existing natural gas and oil resources (Government of Yukon 2019), including 4.6 billion cubic metres (m^3) of gas and 3.2 million m^3 of oil (Hannigan 2014).

The basin has had intermittent periods of oil and gas exploration since the 1950s. Those activities established winter roads, seismic lines, and exploratory wells across the basin, including approximately 40 exploration wells. Eight wells are currently being maintained in suspended status, and the remaining wells have been plugged and abandoned. Seismic exploration within the basin has included approximately 10,000 km of two-dimensional (2D) lines (mostly before 1985), and about 325 km^2 of three-dimensional (3D) seismic was conducted in 2013/2014 (Northern Cross (Yukon) Ltd. 2014).

Chance has completed Project-related baseline studies between 2019 and 2023 including surface and groundwater, permafrost, aquatics and fish, vegetation, wildlife, socio-economic, and heritage resources.



Map 1-1. Chance Eagle Plains Exploration Project Location

1.4 PROJECT ACTIVITIES AND COMPONENTS

1.4.1 Project Activities

Project activities will focus on the following programs:

1. a seismic exploration program;
2. an exploratory drilling program, and,
3. an extended flow testing (EFT) program at select wells.

The seismic program will require up to 1,500 square kilometres (km²) of 3D seismic (2.75 metres [m] wide source lines and 1.75 m wide receiver lines) and up to 2,000 km of 2D seismic (2.75 m wide). The seismic program will include seismic line construction and recording.

Seismic line construction will include clearing of the lines, helipads, staging sites, and temporary creek crossings, and will be done during the winter. Seismic lines will be mulched down to 0.1 m and established approximately 200–300 m apart using a meandering line path. Helipads and staging areas will be cleared as needed, but rely on existing clearings (i.e., treeless areas) as much as possible. Temporary creek crossings will be established in the winter at regular intervals (generally every 5th source line) to facilitate movement of the mulcher and other seismic equipment across creeks and removed before the spring thaw.

Seismic recording will take place during the summer months. This phase of the seismic program will require a helicopter to deploy and retrieve personnel and equipment along the seismic source and receiver lines cleared in the previous winter.

The exploratory drilling program consists of up to seven wells drilled sequentially (one to two wells at a time) per year, to a maximum of 30 wells over the 10-year term of the Project. Each well site will be up to 1.44 hectares (ha). Drill cuttings will be disposed of into a series of mix-bury-and-cover (MBC) pods within a single MBC sump area. formation water, saline fluids, and the liquefaction of drilling fluids and rig wash will be disposed of underground in approved deep-injection wells converted from existing suspended wells.

The drilling program will require winter access roads, including a combination of new access roads (i.e., previously uncleared or used more than 10 years ago) and previously cleared access roads. Roads will be cleared to a minimum of 0.1 m in height (i.e., ground vegetation will be retained) and 8–10 m wide with wider pullouts of 16–20 m spaced every 5 km to allow two-way traffic to pass.

If a well is successful (i.e., the discovery of crude oil or natural gas in sufficient quantities), an extended flow test (EFT) will be conducted at that well, to an estimated maximum of 30 wells. An EFT at an individual well could last for several months up to the end of winter, depending on the well and whether the discovery is principally crude oil or natural gas. The EFT program will be staggered across the Project wells, but it is anticipated that there will likely be at least one EFT occurring somewhere in the Project at any given time during the winter months, with the first EFT potentially occurring in the winter following the year in which discovery is made.

All unsuccessful wells will be abandoned, reclaimed progressively and monitored to assess the progress of revegetation and recovery following the completion of work in an area. Progressive decommissioning and reclamation of access roads will be completed when they are no longer useful or necessary and

monitored to assess revegetation and recovery. At the end of the Project, the MBC sump area and airstrip will be decommissioned and reclaimed, and all active wells will be suspended.

Table 1-1 summarizes the activities that support the seismic, exploration drilling, and EFT programs.

Table 1-1. Summary of Key Activities

Project Activity	Summary of Activity
Engagement	• ongoing engagement with First Nations • ongoing engagement with community residents and other stakeholders
Access Roads	• construction of winter road access for exploratory well drilling, DST, EFT, and seismic program access and execution so will be the first activities of a winter program • clearing woody vegetation along the identified route to near ground level • minimum of 10 centimetres (cm) of packed snow, packing snow and, in some sections, spreading water to create ice on the ground surface • up to 8–10 m wide for two-lane with wider pullouts of 16–20 m spaced every 5 kms to allow for passing traffic • total length of winter access roads per season will vary based on locations identified for exploration drilling each winter; new well sites will be accessed using existing/previously used routes as much as possible to minimize new clearing and linear disturbance • each season, a maximum of 125 km of new (previously uncleared or used more than 10 years ago) winter access roads created • approximately 15% of the roads built on previously disturbed ground (e.g., old roads, cutlines) • maximum of 200 km of winter access roads (new winter access + previously cleared winter access) will be active each season • maintaining and snow-clearing of roads and leases

Seismic Exploration	• access road construction
	• seismic line construction, hazard identification, cutting, surveying:
	  ○ establishment of seismic line rough mulching areas in winter to include:
	  ▪ up to 1,500 km² of 3D seismic (up to 2.75 m wide source lines, 1.75 m wide receiver lines all mulched)
	  ▪ up to 2,000 km of 2D seismic (up to 2.75 m wide)
	  ○ select tree clearing and grubbing will include salvage during the winter, before the construction of the winter access roads; this activity is subject to avoidance by meandering lines across the land to mitigate significant clearing
	• Global Positioning System (GPS) Survey of receiver points and source points
	• Low Impact Seismic (LIS) tracked air drilling of seismic shot holes
	• explosive charge storage (magazines), transportation, and use (1 kilogram [kg] per source point)
	• data acquisition and recording with a wireless system including helicopter use for deployment and recovery of recording equipment and conducting data recording

Drilling Exploration	• winter establishment of up to 30 well sites, each approximately 1.44 ha (120 m x 120 m) within the Project area • tree clearing and grubbing including salvage during the winter, before the construction of the winter access roads • clearing woody vegetation on the well site to near ground level • well site pads will be constructed using packed snow, water to freeze the site, a protective liner and rig mats as required

Project Activity	Summary of Activity

	• up to 30 pads will be constructed and used for exploration drilling over the 10-year life of the Project
	• installation of surface infrastructure on drill sites including:
	  ○ drill rig
	  ○ drilling mud tanks, pumps, and mud mixing and separation systems
	  ○ power generators
	  ○ boilers
	  ○ flare tanks and flare stack
	  ○ blowout preventer accumulator system
	  ○ fuel storage
	  ○ well cement mixing and storage
	  ○ drill pipe and casing laydown area
	  ○ storage bins for rock cuttings removed from the drilling mud
	  ○ trailers for offices, first aid, rig manager sleeping quarters, water storage and treatment, sewage storage, and food waste incinerator
	• drilling wells up to 2,500 m deep:
	  ○ wells drilled sequentially, one to two wells at a time, up to seven wells per year
	  ○ use of low-toxicity, water-based mud system
	  ○ use of an average of 15 m³ and up to a maximum of 100 m³ of water per operating day for drilling and site preparation; higher volumes of water may be needed if snow making or site surface icing is required
	  ○ disposal of drill cuttings into a designated MBC sump
	  ○ disposal of approximately 300 m³ of centrifuged drilling mud and rock cuttings in MBC
	• Drill Stem Tests (DST): one or more on each well at depths where formations with the potential to produce crude oil or natural gas were encountered.
	  ○ potential acid stimulation using approximately 5-10 m³ of a weak concentration of hydrochloric acid (10-20 percent [%])
	  ○ production and separation of fluids recovered from the well during the DST(s)
	  ○ flaring natural gas, separation of crude oil and any produced formation water
	• MBC sump area access for drilling mud and rock cutting disposal
	• disposal of formation water, saline fluids, liquid faction of drilling fluids and rig wash underground in approved deep-injection wells converted from existing suspended wells or wells drilled as part of this Project
	• maintaining and snow-clearing of roads and leases

Extended Flow Testing (EFT)	• installation of surface and subsurface equipment and facilities to enable testing and extended well tests including:
	  ○ casing of entire well bore and perforation of the casing at zones of interest
	  ○ packer, tubing, and downhole measurement gauges
	  ○ wellhead valve assembly
	  ○ flare tank and flare stack gas is to be flared off, and oil is placed in storage tanks. recovered formation water (if any) will be disposed of in deep zone injection wells.
	  ○ separator vessel, treating vessel, and storage tanks
	  ○ appropriate artificial lift systems (e.g., pumps)
	  ○ heaters
	  ○ dehydrators
	  ○ flow lines
	  ○ metering equipment

Project Activity	Summary of Activity
	○ portable generators • conduct EFTs on up to 30 wells: ○ may be completed within a few weeks at a predominantly natural gas bearing zone or may require up to 2 winters for a predominantly crude oil-bearing zone ○ separation of natural gas, crude oil, and formation water ○ potential production of crude oil during EFT and temporary storage for future shipment ○ using natural gas on site for process heating of storage tanks and other vessels, fuelling artificial lifting to assist crude oil production, or compression of natural gas to be used in other areas of the Project such as fuel to heat the camp ○ flaring natural gas during EFT if unable to use on site • gas to be flared off, and oil is placed in storage tanks • disposal of recovered formation water (if any), saline fluids, water from centrifuged drilling mud, and rig wash underground in deep-injection wells will be converted from existing suspended wells or wells drilled as part of this Project. • routine maintenance of facilities, production equipment and well bores, as needed
Well Maintenance (Workovers)	• suspended wells inspected annually, and active wells are subject to servicing on an as-needed basis to address issues that interrupt the EFT, requiring mobilization and installation of a service rig and related equipment on the well site to remedy the problem • maintenance activities include: ○ wellhead inspection pressure test of surface wellhead valves ○ surface casing vent flow test ○ gas migration test ○ repair or replace pumping equipment ○ clear blockages to fluid flow that can develop during EFT ○ replace worn-out downhole equipment ○ set up EFT in other formations within the same well bore ○ suspend or abandon wells after EFT
Mix Bury Cover (MBC) Construction and Operation	• construction of an MBC sump approximately 6.4 ha total in area to dispose of drill cuttings and drilling byproducts • preferred MBC location is an adjacent, previously undisturbed area approximately 63,910 m² south of the Dempster Highway accessed by a winter road located at km 336 • sump will be excavated as disposal volume is required to minimize potential permafrost exposure (possibly in narrow compartments oriented east-west to maximize shading) • each MBC “pod” within the sump will be approximately 800 m² and contain the drill cuttings and spent mud from one well; only one pod at a time will be active/excavated • typical well produces up to 300 m³ of drill cuttings for disposal; development of the MBC would parallel the rate of exploration drilling (i.e., typically 1,500 m^3 of drill cuttings for disposal each year) • removal and stockpile of organic cover material and silts removed during MBC construction for use in reclamation
Central Processing Facility (CPF)	• construction of CPF adjacent to the camp, will allow Chance to store, further treat/separate fluid produced during EFT and transfer it to trucks for disposal. The additional processing enabled by the CPF will stabilize the crude oil, as required for future truck transport to an appropriate approved crude marketing point. The CPF would include: ○ multi-stage and multi-phase separators ○ heat treatment ○ vapour and gas collection system for flares or to provide fuel for camp use ○ processing of crude oil to stabilize and meet specifications for truck transport

Project Activity	Summary of Activity
	○ storage of up to approximately 3,180 m³ of crude oil ○ storage of approximately 119 m³ of formation water • fuel storage facility ○ 151,000 litre (L) diesel fuel ○ 24,000 L propane • storage and use of chemicals and reagents: ○ hydrochloric acid (10% to 20% concentration) ○ methanol ○ additives to prevent corrosion of oilfield processing and handling equipment ○ demulsifiers to be used in treating fluids to better separate oil from formation water • bulk explosive compound to store dynamite charges for seismic exploration.
Airstrip	• construction of an airstrip approximately 1,500 m long located at about km 4 along the Chance winter road from the Dempster Highway intersection • airstrip will be used only during the winter when the surface can be levelled using winter road construction techniques. if sufficient air traffic support is required, Chance may upgrade the airstrip to year-round usage. • airstrip will be used throughout the project life, approximately two flights per week. • Jet-A aviation fuel will be stored at the airstrip
Water Withdrawal	• use of up to 300 m³ of water per day (or per permitted limits) for camp use and for making ice as part of building winter roads, ice roads and temporary well sites, not exceeding 10% of the instantaneous flow from the following extraction points: ○ year-round extraction from the Eagle River, Ogilvie River, and Whitestone River ○ extraction from Glacier Creek for fly-in camp ○ use up to 20 m³ of water daily (for washing, showers, toilets, etc.); bottled drinking water will be supplied to the camp for human consumption ○ construction of a water reservoir at the camp for water storage and use during low water periods. This may be filled during the summer when surface water flow rates are high. Two insulated water tanks are available for water storage with a capacity of 400 and 700 US barrels (liquid)
Transportation	• use Dempster Highway, North Klondike Highway, and Alaska Highway to access Project site; alternate access could include Highway from Watson Lake to Carmacks • approximate offsite traffic on public roads between the site and supply points estimated at: ○ 7–10 water trucks per week ○ up to 3 fuel trucks per week ○ 10 lightweight service vehicles per week as needed • Onsite traffic on Project-controlled roads is estimated to be: ○ fuel and water deliveries at a rate of 5–8 trucks per week ○ lightweight service vehicles daily to transport personnel and gear from camp to well sites, and for use by monitors
Chance Camp	• opening the existing camp and mobilizing equipment and personnel including drilling and seismic crews • continued use of existing 75-person Chance Camp, located at km 325 of the Dempster Highway. ○ up to 75 people on-site during all Project components: ○ existing waste management and disposal facilities ○ existing wastewater treatment infrastructure

Project Activity	Summary of Activity
	• remote camp for up to 25 personnel will be established near the proposed East Greaves and West Greaves Winter Roads, roughly 40 km from the Chance Camp to improve safety and access to sites • mobile camp will be set up at each active well to house the crew as needed (typically three personnel) • up to three secondary camps will be established in remote parts of the Project area to support safety and staging of exploration • Eagle Plains Hotel will be used to accommodate personnel overflow for short periods, if required
Reclamation and Closure	• progressive abandonment and reclamation of unsuccessful wells • wells that have successfully undergone EFT will be suspended pending future development considerations • installation of cement plugs across all porous/permeable zones within the well bore, across the base of each casing section and including an overlapping portion below the surface casing with the base of the surface casing • cutting a surface portion of well casing(s) off at least 1 m below ground level and welding steel plates to cap the casing • MBC sump area will be reclaimed as per available legislation and industry best management practices, including YOGA and *Directive 050 Drilling Waste Management* (Alberta Energy Regulator [AER] 2023) • removal of equipment, matting, materials, and debris from well sites • natural revegetation of low impact seismic lines • progressive decommissioning and reclamation of access routes when they are no longer necessary • testing facilities are to be removed from each site • upon complete field decommissioning activities, the removal of the CPF will occur • airstrip will be decommissioned and reclaimed at the end of the Project

1.4.2 Project Phases

The Project will have only one phase; the exploration phase, spanning 10 years.

1.4.3 Project Stages and Schedule

Field activities for the Project are planned to begin in winter 2025/2026 following the completion of the YESAB Executive Committee Screening Process. Within the 10 years of the exploration phase, work may be broken up into work stages (3 work stages, for example), with activities in each stage lasting 1 to 3 years, in each of the presumed three work areas. Each area is expected to encompass approximately one-third of the total Project area. The extent (size, location, and boundaries) of work areas will be developed iteratively over the Project's life based on existing and future exploration results).

Up to seven wells may be drilled sequentially per year, to a maximum of 30 wells over the 10-year life of the Project. The sequence in which wells are drilled for the exploration program depends on previous drilling success, EFT results, data collected from the seismic exploration program, weather, and road conditions. The ongoing process of interpreting seismic data will allow Chance to better understand the geological setting and size/geometry of the potential prospect.

Most of the activities will occur in the winter (e.g., seismic line clearing and shot hole drilling). Work outside of the winter includes aerial-supported seismic recordings. Conducting the seismic grid and shot hole drilling programs in the winter is expected to minimize the Project's effects on terrain, terrestrial and aquatic resources. The seismic recording will take place in summer to minimize ground disturbance and reduce Health, Safety and Environment (HSE) risks.

1.4.3.1 Seismic Exploration Program

Seismic exploration will take place year-round. The line preparation (access road construction, line cutting, surveying, and drilling) and the establishment of temporary creek crossings will be conducted during the winter months (potentially starting in October but likely December through April) under frozen ground conditions. Before spring thaw, temporary creek crossings will be removed. Recording would then follow in the summer months (June through September). This involves using a helicopter to deploy and retrieve personnel and equipment to the exploration area where geophones will be placed on the receiver lines and a shooter will detonate the previously loaded charges in a prescribed sequence. A brief outline of the annual schedule is shown on **Figure 1-1**.

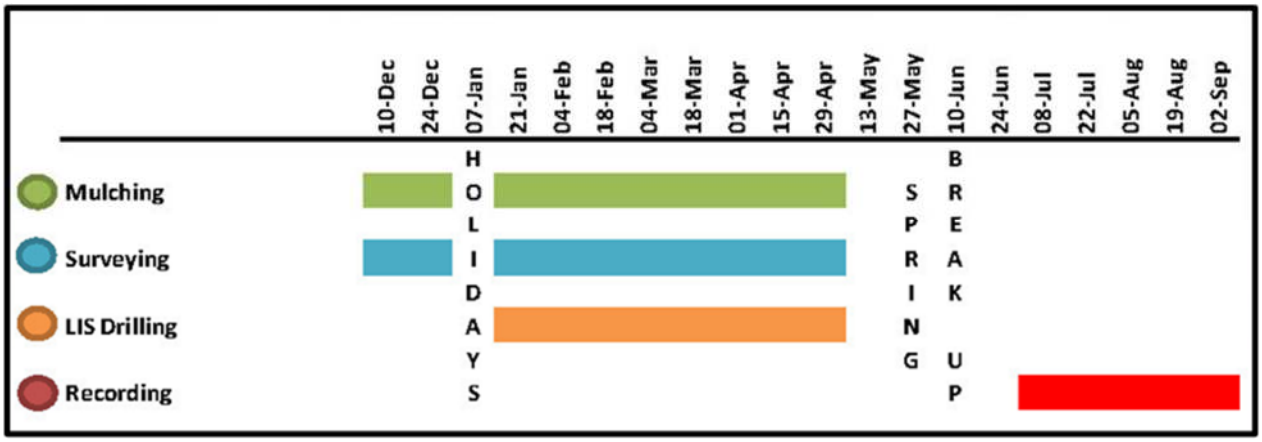


Figure 1-1. Proposed Year-round Schedule for Seismic Exploration in Eagle Plains

The seismic exploration program will consist of up to 1,500 km² of 3D Low Impact Seismic (LIS) data acquisition and up to 2,000 km of 2D LIS data acquisition. Seismic exploration relies on the geophones placed in a single line (2D) or along multiple, usually parallel, lines (3D). The 2D program may be undertaken as a single program or several smaller programs; the 3D program will be conducted as several programs of 400–700 km² areas. The winter seismic programs will minimize terrain, terrestrial and aquatic environmental effects. The seismic recording will take place in summer to minimize ground disturbance and reduce Health, Safety and Environment (HSE) concerns.

1.4.3.1.1 Seismic Recording and Drill Locations

Seismic exploration uses a compressional seismic p-wave (like an ultrasound) to remotely image rock layers beneath the surface. The technology measures the reflected energy waves (p-waves), akin to multiple echoes from each rock layer, to identify geological settings where oil and natural gas might be located. This imaging allows geophysicists and geologists to map the subsurface structure of rock

formations that could contain hydrocarbons and help pinpoint areas of the greatest potential for drilling a successful well.

Small dynamite charges in shallow holes, called shot holes, are used to create the p-waves that reflect off the various rock layers underground; the reflected p-waves are recorded by sensitive devices called geophones The small dynamite charges within each shot hole force the energy downward through the various rock layers. A seismic detonation of one kilogram (kg) is comparable to the sound of a passing diesel truck and is only 0.5 seconds in duration. Little reflected energy is perceptible at the surface by anything other than the sensitive geophones. The p-waves reflect off the various rock layers underground like and echo. As the energy bounces back to the surface, the geophones detect the seismic waves and record the data (**Figure 1-2**). The time it takes to receive the sound wave from the detonation tells geophysicists and geologists where the rock properties change, helping to find the oil and gas deposits.

Once all source points have been detonated in sequence, the data are processed and analyzed. The interpretation of the seismic data can give geophysicists detailed cross-sections (2D seismic lines) and multi-dimensional graphics (3D seismic programs) of the sub-surface area. This information is combined with previously known information about the rock types within the area and their properties, such as hardness, density and porosity, to support drilling locations for wells. The decision to drill wells or acquire additional seismic is determined by the amount and quality of the data available (**Figure 1-3**).

Decisions to drill wells or acquire additional seismic data is an ongoing process to define the resource potential in a particular geological formation or geographic region and is a combination of geological and geophysical efforts. The process includes ongoing seismic acquisition and geological evaluation as the wells are drilled and production capabilities are examined.

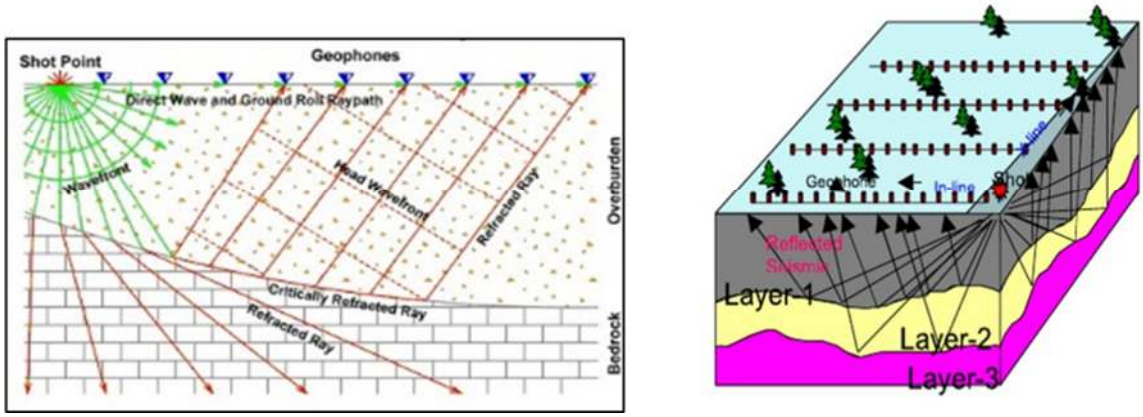

Figure 1-2: A Graphic Example of the Reflection Seismic Exploration Data Collection Process.

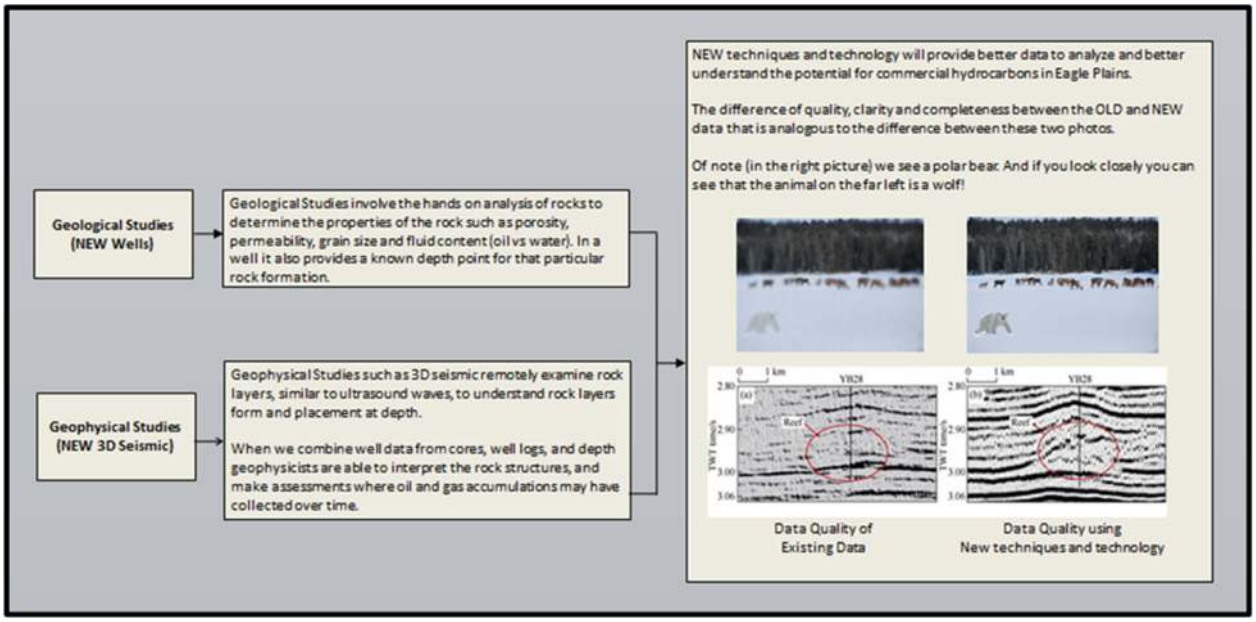

Figure 1-3: Example Geological and Geophysical Studies

1.4.3.1.2 Seismic Data

Seismic data is required in the Eagle Plains Basin to understand the area's complex geology. Modern seismic techniques will provide high-quality information about the geology of Eagle Plains while minimizing environmental effects. The proposed area for seismic exploration consists of about 1,500 km² of new 3D and 2,000 km of new 2D reflection seismic exploration within Chance's exploration permit area. **Map 1-2** illustrates the extent of the exploration area. However, the location of each annual seismic program, whether 2D or 3D, will be determined by analyzing the exploration drilling results and how seismic may help determine the knowledge of the basin. Low Impact Seismic 2D programs can be used to determine the extent or edge of a prospect, and LIS 3D will show more detail.

Depending on available accommodations, personnel, and equipment, the seismic data will likely be acquired in several discrete programs of approximately 400–700 km² areas. Year-round operations will enable resource allocation by completing line preparation during the winter and conducting the recording activities during the summer using heli-portable operations. Lines will be prepared in winter when snow is present, and the ground is frozen. Winter ground preparation will protect the active layer and underlying permafrost and preserve saplings and small shrubs. Year-round operations will enable larger portions of the seismic program to be completed with reduced disruption within the Project area.

For LIS 3D, a design is created by a professional 3D designer. For the Eagle Plains area, receiver lines will have an east/west orientation, and source lines will be oriented north/south. The spacing between points is determined by the level of data resolution required to image the shallowest rock formation of interest. It is estimated to vary between 40 and 50 m since the geology at Eagle Plains dips from the northeast (NE) to the southwest (SW). For a given layer of rock, it will be physically shallower in the NE part of the basin and deeper in the SW. The receiver lines will be mulched with the narrowest mulch head size (1.75 m wide), allowing for safe travel by foot, snowmobile or all-terrain vehicles (ATVs) and will run roughly parallel to other meandering receiver lines spaced approximately 200 m apart. The north-south source lines will be

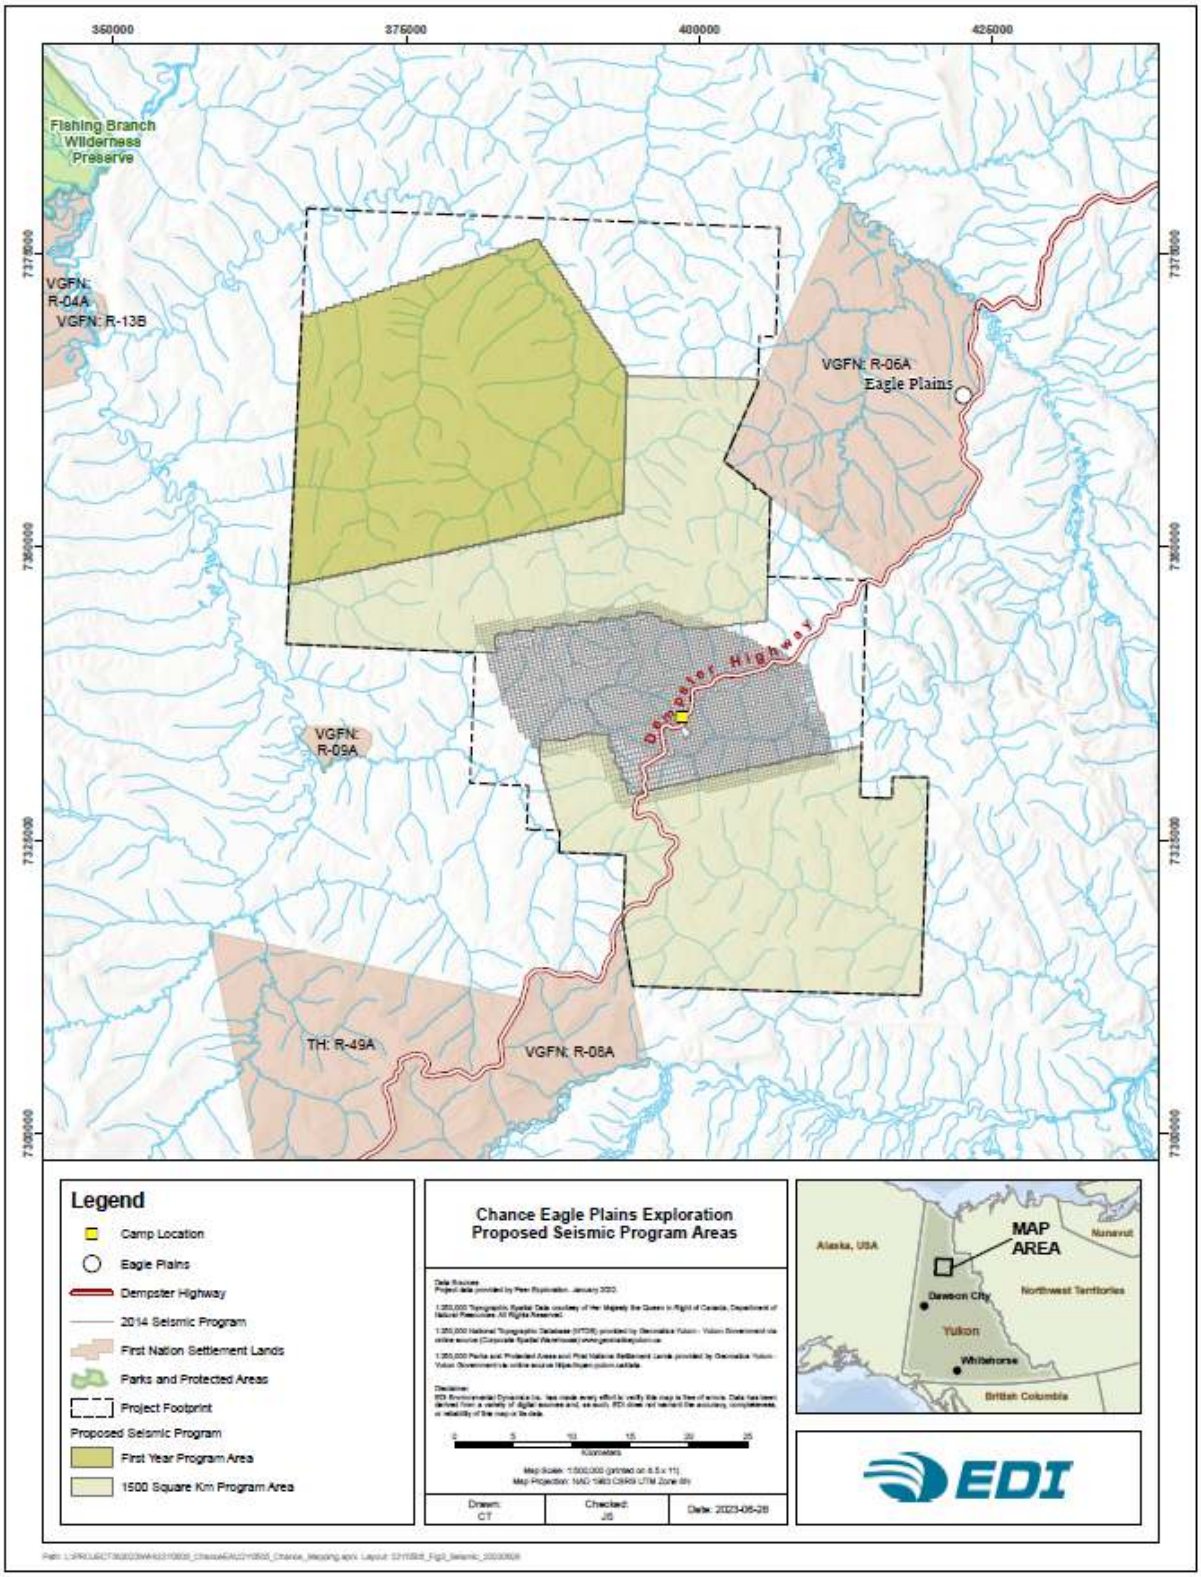
mulched (2.75 m wide) to allow access for the tracked drills that make the shot holes. The source lines run roughly parallel to other meandering source lines approximately 300 m apart. For LIS 2D, the geophones and sources are located within the same meandering, about 2.75 m wide, line.

During the recording process, each source point is detonated separately upon the initiation of a radio signal directed by the field operator called a “shooter”. The shooter is positioned at least 30 m from the active station and can survey the surrounding environment to observe detonation safety. The source point that will be detonated is in the source “swath” area and provides a centre point for the recording patch. A recording “patch” is the area of live (active) geophones that are closest to the source point swath area (within 3,000 m). Upon detonation of the source point within the swath, the geophones in the recording patch collect the data. For the Eagle Plains area, the patch size is comprised of 16 lines containing 140 geophones each (**Map 1-2**)**.** The patch ensures that far offset distances are greater than the depth of target formation; therefore, the data will encompass areas large enough to prevent gaps in the data. The patch is moved digitally and physically as the shooter travels from east to west and then north to south. Geophones are continually picked up from the recorded area and moved to the next area ahead of the recording patch.

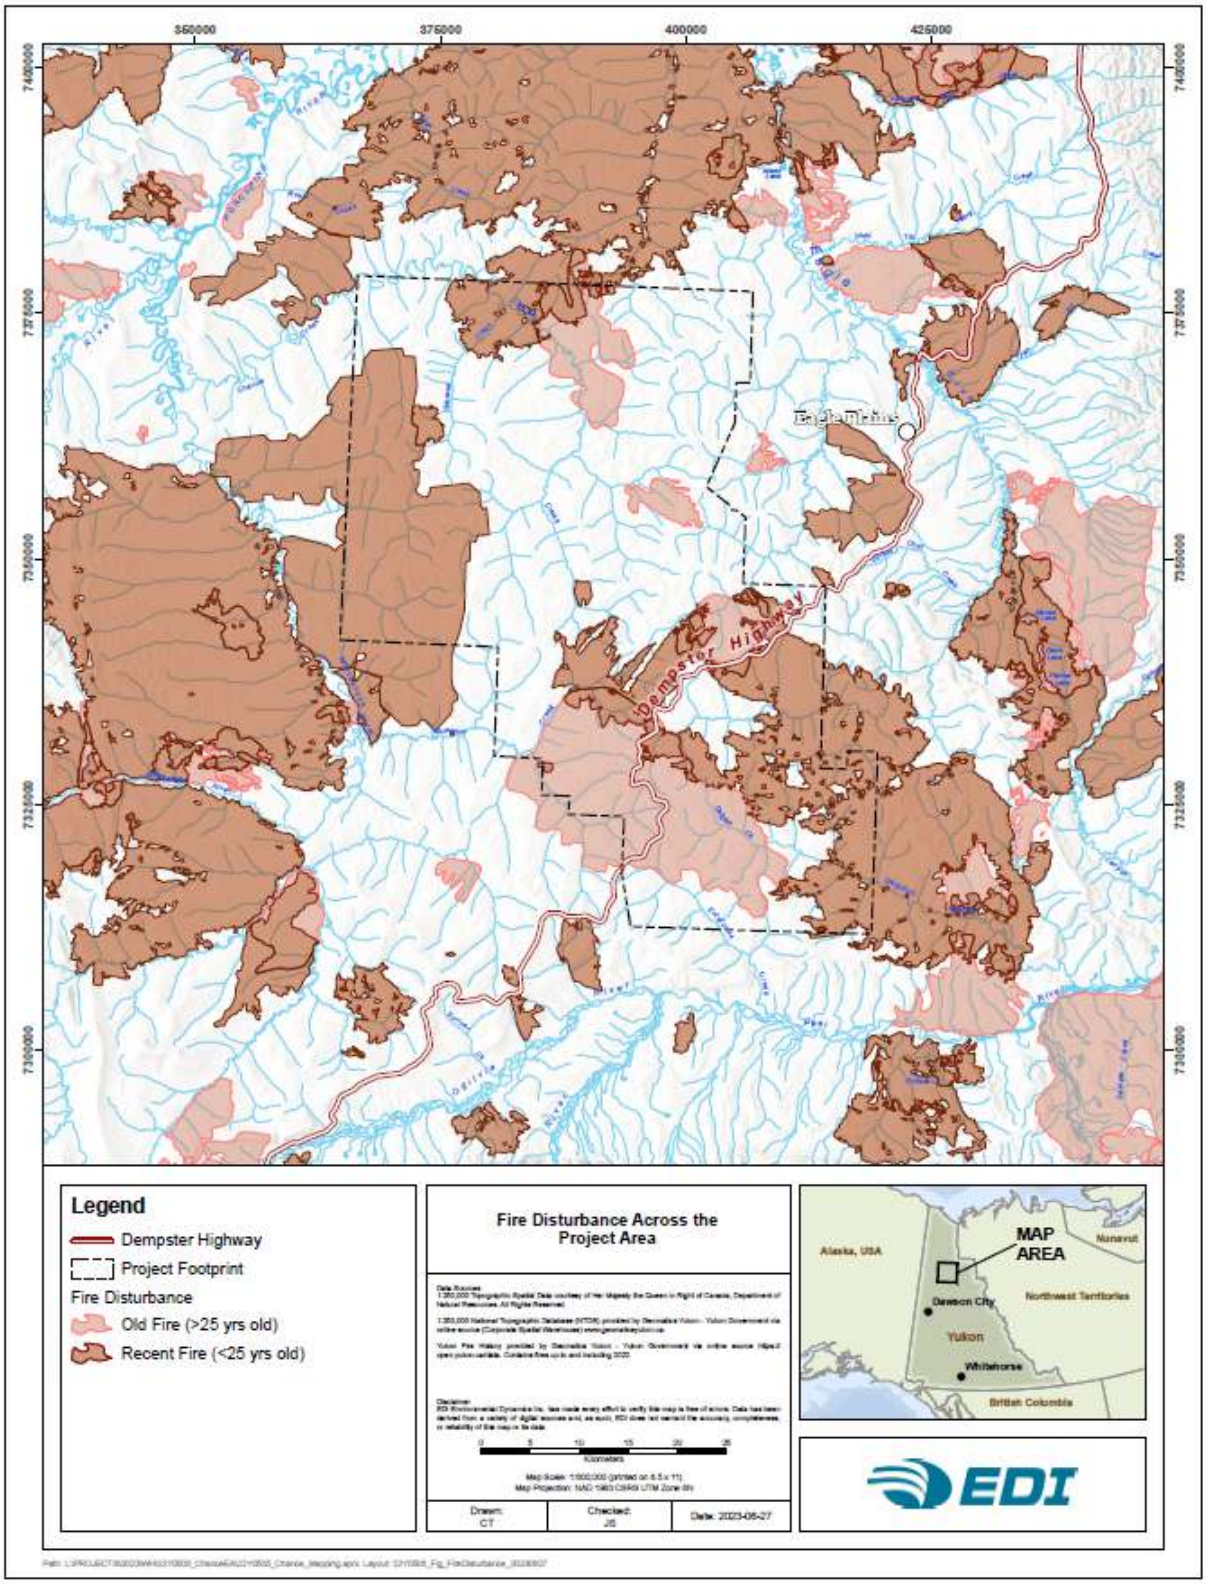
As seismic program data will be acquired over several years, naturally occurring fires are likely in the area. Several fires have occurred in the Eagle Plains basin, and approximately 60% of the Project area has been burned. The most recent wildfire occurred in 2017, burning 294 km² within Chance’s exploration permits 0010 and 0012 (**Map 1-3**).

Each year that a seismic program with be conducted, an analysis of mitigation strategies is undertaken, and appropriate strategies are implemented to reduce the environmental effects in the area. One example is using existing burn areas rather than clearing new vegetation where possible. The proposed first-year seismic program was designed considering the existing open meadow and burn areas. Lines traversing these areas will not disturb live vegetation and should not be regarded as a functional disturbance. Regrowth in these areas will also be monitored to gauge the natural regeneration conditions in the area. Previous LIS seismic line disturbances will continue to be analyzed to make sure that current methods of line preparation provide optimal conditions for regrowth in the Eagle Plains area. Ecological, permafrost and historical data have been extensively gathered and incorporated into the operations plan.

Seismic operations are planned for year-round operations in the year that they are to be conducted, based on length of time required to conduct each component of the program and the limited personnel, equipment, and accommodations available in the Eagle Plains area. The line preparation (access trail construction, line cutting, surveying, and drilling) will be conducted during the winter months (December through April) under frozen ground conditions and recording would then follow in the summer months (July through September) (**Figure 1-4**).



Map 1-2: Chance Eagle Plains Exploration Proposed Seismic Program Area



Map 1-3: Forest Disturbance Across the Project Area

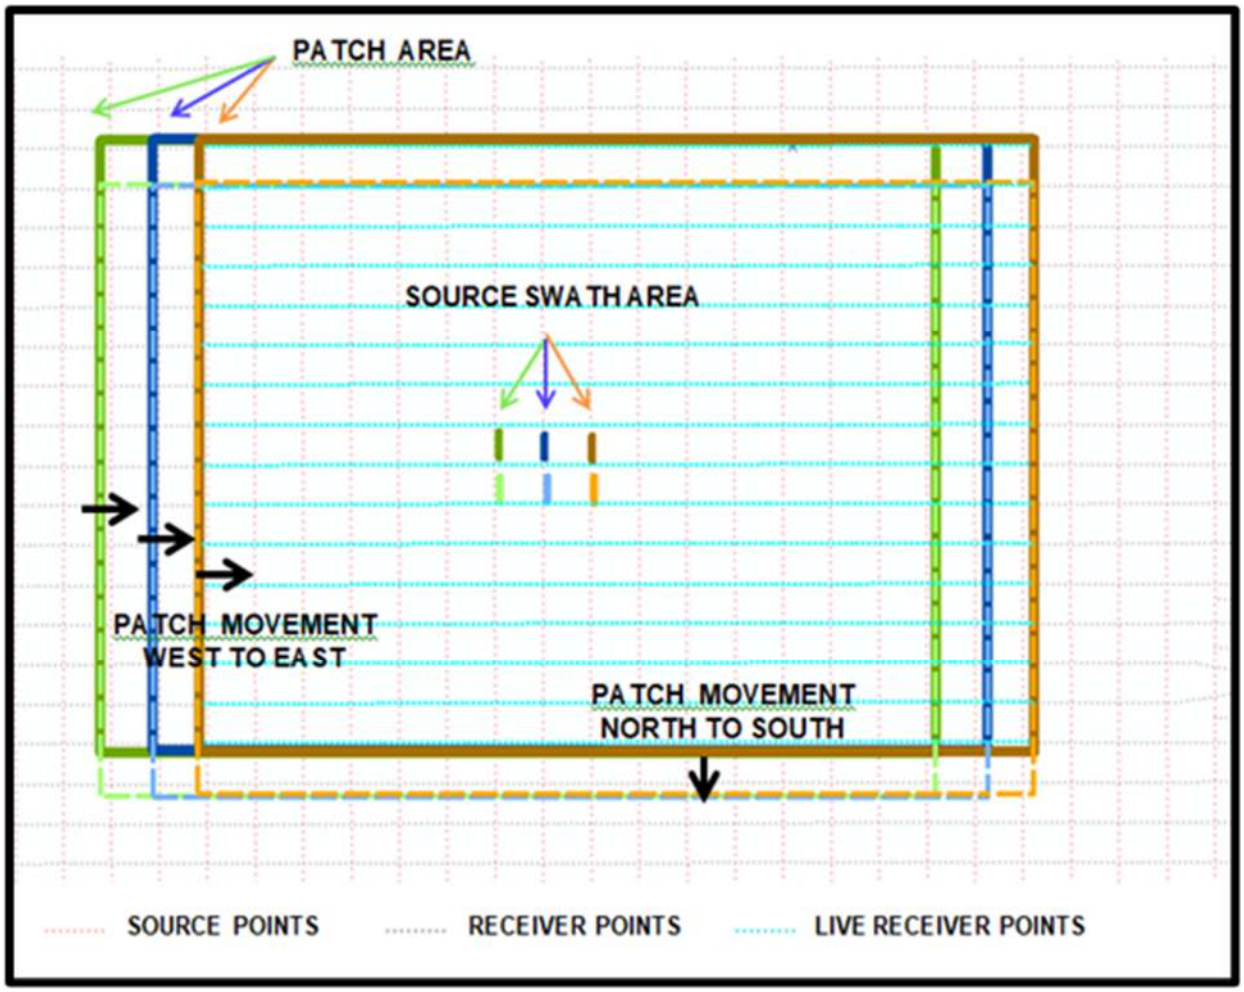


Figure 1-4: Proposed Seismic Patch Size and Movement Throughout the Program Area.

1.4.3.1.3 Seismic Line Construction

The historical seismic data in the Eagle Plains area consists of "Legacy" 2D seismic lines and the "Modern" LIS 3D seismic program conducted in 2013–2014. The methods used to construct the Legacy 2D lines included 6–10 m wide lines in straight (linear) patterns that cross the landscape. These lines are visible today mainly due to the past use of bulldozers to remove over/understory — these clearing methods and wider lines are not required in modern LIS practices. Modern LIS line construction methods use narrow line widths that meander and create non-linear line disturbances. Bulldozers are no longer used in seismic line construction; smaller and narrower mulchers are now used to support the preservation of the active layer and reduced vegetation removal.

Line preparation will use the LIS methods, reducing the landscape footprint. This technique creates meandering source and receiver lines that limit the line of sight to less than 70 m, which minimizes predator (e.g., wolf) line of sight for prey. The LIS method also ensures that the line can avoid removing larger timber that shelters under canopy vegetation by adjusting the meander of the line to avoid larger trees and mature vegetation.

1.4.3.1.4 Line Preparation — Cutting

A combination of mulchers and operators with chainsaws will prepare source and receiver lines that will be closely monitored and quality controlled. Mulchers (**Photo 1-1**) are equipped with GPS units with seismic line data to allow the operator to follow a pre-planned course. Mulcher operators have detailed information on the area's pre-identified hazards or constraints, culturally sensitive locations, flora and fauna setbacks, and course derivations, and the operator takes care when approaching these areas of concern. Lines will be doglegged (or bent) at locations crossing any major access trails and open clearings to reduce the visual identification of access points into the program area. Meandering line construction chooses the path of least resistance and avoids timber larger than 20 to 30 cm in diameter (**Photo 1-2** and **Photo 1-3**). This technique reduces the line of sight down line to less than 70 m.

Source lines will be mulched to 2.75 m wide (**Photo 1-4**) to accommodate tracked LIS drill vehicles, and receiver lines will be 1.75 m wide (**Photo 3-3**) to accommodate snowmobiles, ATVs and personnel. A minimum of 60 cm of packed snow will be left online to mitigate possible damage to vegetation or permafrost. Riparian areas and lines containing pokers or leaners will be hand cleared with chainsaws.

The seismic line preparation will be done using rough mulching: a technique that removes the branches but leaves the tree stems intact. This technique is useful in leaving evenly distributed coarse, woody debris allowing for more rapid decomposition of the fallen timber while enabling the new vegetation to propagate through the mulch (**Photo 1-4**). The mulcher heads are set to high blade, leaving the active layer undisturbed and soil or permafrost unaffected. The mulch also protects the root system of young timber from heat, cold, drought and erosion. Rough mulching makes lines narrower, creating more natural lines with weakly defined cut-width edges.

Since creeks in the program area freeze to the bottom in winter, no "major" watercourse crossings will be required. A major watercourse crossing is any stream or river that will not freeze to the bottom or the water flow is too great to sustain a snow fill crossing. Crossings are categorized as mechanical (equipment crossing) or foot crossing. The mechanical crossings (**Figure 1-5**) will be constructed using snow fills and may require a water truck to make snow and freeze in the crossing. Water crossings are first packed with clean snow pushed from the creek surface to the crossing location. This prevents woody debris from contaminating the creek during spring melt. The snow is then hardened using a water truck to form ice to strengthen crossing integrity with the weight of the equipment. Snow fills in both creeks and drainage areas will preserve the integrity of the banks for adequate water flow and run-off. All crossings will be removed before spring break-up to allow obstruction-free drainage. Given the Eagle Plains area has very low tree density, creeks often have natural areas to cross where vegetation removal is not required. Where vegetation clearing is required near a creek, the root system remains intact to maintain creek bank stability. All snow fills will be constructed following the Department of Fisheries and Oceans (DFO) Code of Practice: Ice Bridges and Snow Fills. (Fisheries and Oceans Canada 2023).

Riparian areas are also examined and added to the program map. Since riparian areas provide key resources for wildlife and bank stability, mechanical equipment is restricted to a 45 m setback from the bank edge. This setback protects vegetation disturbance in the area and makes sure source holes terminate at a safe distance to avoid flowing holes (**Figure 1-6**).

1.4.3.2 Line Preparation — Surveying

Once there are a sufficient number of source and receiver lines cut to allow the next stage of the seismic program to occur, surveyors then travel the source lines using ATVs and snowmobiles to survey and mark each drill location of the source holes; on receiver lines they mark the receiver points where the recording crew will place the wireless geophones.

Surveyors also contribute to the hazard/sensitive site assessment map as they record their GPS data. These data include:

- riparian areas;
- difficult terrain;
- historical/archaeological areas;
- animal sites/features;
- facilities;
- hazard identification;
- proper line placement;
- movement around thick bush;
- refining cutting requirements; and,
- flag all hazards or constraints and riparian areas.

1.4.3.3 Line Preparation — Drilling

Once source points are surveyed, narrow-tracked LIS drills (**Photo 1-5**) are deployed to drill a 10 cm diameter, 6 m deep hole at each location. For the proposed seismic program in Eagle Plains, the source points will be spaced along the source lines at approximately a 50 m interval.

Photo 1-5. Narrow Low Impact Seismic (LIS) drills

No water was required to drill the source holes during the 2014 seismic program, and cuttings were easily reloaded into the hole chamber after the dynamite was placed at the bottom of the hole. Source holes are loaded with 1 kg of dynamite to be later detonated by the recording crew (this is called pre-loading). As provincial/territorial and federal legislation requires, each source point is plugged with drill cuttings (soil, rocks, etc.) brought up to the surface from the drill stem). An industry-approved plug is inserted into the hole at a minimum depth of 30 cm below the surface and then filled to the surface with more drill cuttings.

Chance and the industry's explosive providers are aware of the regulations under the federal *Transportation of Dangerous Goods Act*, S.C. 1992, c. 34 (Government of Canada 1992) and strictly adhere to those regulations. Explosives will only be transported in approved magazines and by individuals trained in transporting dangerous goods. Natural Resources Canada (NRCAN) regulates and controls all aspects of explosive possession and transportation through magazine licences which are renewed annually. The new Electronic License Management System (eLMS) allows up-to-date management of all explosive purchases, transport, and incidents to ensure explosives are tracked and safely stored. The two types of magazines that will be used to store explosives are as follows:

Maxam Type 9 Magazines (Photo 1-6):

- There are two compartments — dynamite and detonator.
- Type 9 magazines are lined with 7/8" Armortex (Bullet Proofing and Blast Resistant). Dimensions are 58" wide x 144" long x 66" high.
- Doors are high security and built as per NRCAN Regulations and issued a Federal Tag #.
- There will be two different sizes of skidded Type 9 magazines which will store up to 3,000 kg of explosives and 5,000 detonators, depending on packaging. There are also wheeled Type 9 magazines built to the same specifications but with reduced capacities.
- Construction from the outer skin to inside is:
    - ¼" steel plate;
    - 7/8" Armortex; and,
    - ¼" plywood interior.
    - Weight is 7,500 pounds (lbs).
    - These magazines are transported by either small custom-built tandem axle trailers, tandem axle recovery/tow truck with a flat bed or any truck trailer unit such as a low boy.

Maxam Type 4 Magazines:

- Single-compartment magazine;
- Various sizes — 8' wide x 12' long x 7' high with a capacity 7,500 kg;
- High-security door construction as per NRCAN Regulations and issued a Federal Tag #;
- Construction from the outer skin to inside is:
    - ¼" steel plate;
    - 3" gravel;
    - ¾" plywood interior.
    - Weigh 18,000 lbs; and,
    - These magazines are transported with either a tandem axle recovery/tow truck with a flat bed or any truck unit such as a low boy.

Photo 1-6. Explosives Magazine Storage (Maxam Type 9)

1.4.3.3.1 Data Acquisition — Recording

Recording the seismic program consists of two stages: laying out and picking up equipment on the receiver lines; and detonation at each source hole.

Geophone "Layout"/ "Pick-up" — Line crew members place the geophones (**Photo 1-7**) and associated equipment at each receiver point location. Using a long line and heli-bags, a helicopter will place and retrieve recording equipment along the receiver lines at predetermined intervals. Recording personnel will access the equipment in the heli-bags and place a series of geophones approximately every 40 m along the receiver lines. The recording crew will be using a cableless recording system. Cableless recording systems are ideal for gathering seismic data because they reduce the constraints on geophone placement, eliminate downtime for cable repair, and reduce the number of crew members required to deploy the equipment. Once in place, the geophones record the seismic waves created by the charges detonating on the source lines. Once the section of geophones is recorded, personnel and a helicopter return to retrieve the equipment and any debris used to mark the surveyed receiver locations. The geophones are returned to the staging site, downloaded, cleared and deployed back to the program to be laid out again to record the next section of line.

Photo 1-7. Example of a Geophone

Source Point Detonations — This stage begins after the first section of geophones has been laid out on the receiver lines. Specially trained personnel called “shooters” traverse the source lines on foot, via ATVs or snowmobiles, to each source point. The shooter examines the area around the source point for any possible hazards, constraints, or wildlife and inspects the condition of the leads. They connect the detonation device to the leads and signal to the Observer (located at the staging site) that the charge is safe to detonate. The shooter stands clear of the source hole (approximately 30 m) but remains within viewing distance to watch the area remains clear. A specific radio signal initiates the detonation, and the shooter returns to the hole to remove the detonation device, the leads, and any flagging or markers in the area. The shooter then proceeds to the next source point and repeats this procedure.

Once the program is complete, a crew may be deployed to clean up any remaining material used online for the seismic program. The garbage is returned to a staging point and discarded in an approved bin to be transported to a waste facility. The crew also reports issues that may require further reclamation to be immediately addressed.

During the recording stage, the equipment on the source and receiver lines is accessed by foot, ATV, snowmobile or by helicopter. The helicopter will be based out of the Chance Camp at km 325, and the use of the helicopter will be minimized. Where possible, the helicopters will be sourced from local operators familiar with the environment and the guidance document *Flying in Caribou Country* (Government of Yukon

2010); however, specialized long-lining operators will be required outside Yukon for the recording operation. The addition of helipads will also be required for safety and medevac reasons but will be selected in naturally open and sparsely treed areas.

Staging sites will store some or all of the following equipment throughout the seismic program. All equipment is moved to the next staging site as the equipment is required in the next area of the program:

- Trucks (1/2, 3/4, and 1 ton);
- ATV and snowmobiles;
- Trailers (flat decks and covered);
- Double-walled fuel tanks (diesel 145,228 L, Gas 83,825 L and Jet-A 35,000 L)
  - The fuel will be contained at the main camp in double-walled tanks and transported to the staging sites in a 2,000 L tank trailer for use during operational activities in each area.
- Helicopter & fuel tanker;
- Picker trucks (1-ton trucks with equipment);
- Recording bags;
- Garbage bins to temporarily store garbage before incineration;
- Magazine;
- Survey and drill supplies;
- Canvas tents;
- Medivac unit;
- LIS drill units;
- Seacan for storage and tools;
- Snow cats;
- Water truck;
- Battery truck; and,
- Mulchers.

1.4.3.4 Exploratory Drilling Program

Drilling will be conducted during winter, primarily from January through March. The sequence in which wells are drilled depends on previous drilling success, EFT results, data collected from the seismic exploration program, weather, and road conditions. The following is a brief chronology of the progression of a drilling program:

- Review seismic and other data to help guide prospect definition and well locations.
- Develop winter access road to well site.
- Clear vegetation as needed, and conduct site levelling (see below).
- Install surface infrastructure for drilling and testing the exploratory well on the well site.
- Drill the well.
- Transport and dispose of drill cuttings in the MBC sump via winter access road.
- Well logging and core sampling before conducting DSTs.
- Conduct DSTs to determine whether EFT should be conducted.
- Case and suspend the well or abandon and reclaim depending on results.
- Move the drill rig to the next well site area.

Temporary drilling pads will only exist during winter and will be created from snow on areas cleared of trees and tall vegetation; the ground will remain undisturbed. Levelling will be done by building a snow and ice base. Rig mats will then be positioned to help with levelling and distribute the load of equipment sitting on top. If the DSTs are unsuccessful (i.e., no commercial quantities of petroleum products were encountered in the well), well abandonment or suspension will be completed, followed by progressive reclamation. A

suspended well is a well that is not producing and has been safely secured, but production could be restarted later. An abandoned well is a well that has been permanently shut down, appropriately plugged, and the well head removed, as defined in the Yukon *Oil and Gas Drilling and Production Regulations*, YOIC 2004/158 (Government of Yukon 2004) (*OGDPR*); it can then be considered safe and secure by regulators.

Well abandonment or suspension includes:

- abandon well (cement all perforated producing zones, install shallow cement plugs, and cut surface casing 1 m below normal ground surface); or,
- suspend well to become an alternative location for deep zone injection (finish casing, perforate the casing, and install production flow control devices, steel tubing, and wellhead components).

Progressive reclamation includes:

- remove all surface infrastructure;
- remediate well site area.
- Recontouring of the well site areas is not anticipated as well site contouring will be limited to levelling the area using packed snow and ice; therefore, there will be minimal disturbance to the underlying vegetative layer.
- An example of a typical rig at night, and as viewed during the day at the end of a constructed winter access road are shown on **Photos 1-8** and **1-9.**

Photo 1-8. Example of Typical Chance Rig at Night

Photo 1-9. Example of Typical Chance Rig at End of Constructed Winter Access Road

1.4.3.5 Extended Flow Testing

If the DST is successful (i.e., petroleum products in quantities deemed commercial were encountered in the well) an EFT would be conducted. Successful wells will be suspended as an intermediate step to cover timing differences between finishing the DST, finishing drilling the well, and undertaking an EFT. More than one DST could be done on a well if there are multiple geological formations with potential commercial quantities of hydrocarbons. An EFT at an individual well could last from several months to the end of winter, and up to two consecutive winters depending on whether the discovery is mainly crude oil or natural gas. An EFT generally includes the following activities:

- Install surface and sub-surface equipment required for the EFT.
- Complete the well with tubing and downhole gauges.
- Perforate casing at zones of interest to allow natural gas and natural gas liquids to flow into the well bore (hydraulic fracturing is neither proposed nor required to perform an EFT).
- Allow the well to flow, flare gas, and collect oil, natural gas liquids, and other fluids.

Well completion is the process of readying a well for production after drilling and may include the following tasks: perforating the casing, installing production flow control devices, and installing steel tubing and wellhead components. Further details on the EFT process, including pre- and post-EFT tasks are outlined in **Table 1-2**. **Figures 1-7** to **1-9** show typical schematic process diagram for a DST, a typical flare stack and gas/vapour recovery flowsheet, and typical flare stack unit on a portable rig.

1.4.3.5.1 Well Maintenance

Any well completed for and EFT, or not completed for an EFT and suspended, may require maintenance during the 10-year life of the Project. Well maintenance is required on any suspended well before abandonment, conversion to an active well, or annually if it remains suspended. Well-maintenance equipment may include a service rig, wireline truck, cement trucks, and associated support equipment. Under the *OGDPR*, a well is deemed suspended when it is safely secured, but is not producing oil or natural gas.

Well maintenance activities, also known as workovers, generally include:

- pressure testing to confirm the integrity of the casing and well head valves;
- removal of equipment in the wellbores such as tubing and plugs;
- wireline investigations to measure temperatures and cement integrity and convey any perforating equipment;
- remedial work such as cement squeezes or treatments to improve flow from the reservoir rocks into the well bore; and,
- well bore integrity assessment.

1.4.3.5.1.1 Pressure Test and Surface Casing Vent Flow Test and Gas Migration Test

A pressure test will be conducted at each well to evaluate the integrity of the wellhead and the existing well bore casing. The well (or Legacy well) will then be tested for surface casing vent flow (SCVF) and gas migration in the area immediately surrounding the well head. Chance reports that no SCVF has been detected in existing suspended wells during annual inspections.

If SCVF is identified, the well will be inspected, and test results will be logged using various tools (e.g., noise tool, temperature tool, bond log tool) to determine the source of the SCVF and/or gas migration. The logs will be analyzed, and a plan will be formulated to complete a downhole shut-off at the source of the SCVF or gas migration if required. This is only done for significant vent flow events or when abandoning a well. Non-significant vent flows are normally left until end-of-life for newly producing or suspended wells.

Depending on the status of the well (e.g., cased or completed with perforations) and the nature of the problem, the equipment needed to fix the problem will typically involve some combination of a service rig, wireline services and possibly cementing services.

1.4.3.5.1.2 Temperature Log and Cement Bond Log

Once SCVF and gas migration testing is complete, the service rig, support equipment, and wireline will be moved to the well site. A temperature log will be recorded from the surface to 300 m Kelly Bushing below the surface (mKB) to identify anomalies or departures from the reference gradient. Most anomalies are related to fluids entering the formation through the borehole or fluid exit. If there is no anomaly, this work will be a measure of the depth and thickness of permafrost.

A cement bond log will be run after the analysis of the temperature log. The cement log uses the variations in the amplitude of an acoustic signal travelling down the casing wall between a transmitter and receiver to determine the quality of a cement bond on the exterior casing wall. The acoustic signal will be more attenuated in the presence of cement than if the casings were uncemented. The cement log is used to identify sections of the well bore that will need intervention to isolate porous formations from adjacent formations through new cement squeezes.

1.4.4 Project Design Stage

The Project is currently designed to a conceptual level. Project facility locations combine known, fixed spatial locations (e.g., camp location) and undefined spatial locations that will be determined as the seismic and drilling programs gather data. Detailed Project design will be done iteratively throughout the life of the Project based on data gathered through Project progression. It will conform to the commitments made by Chance and the terms and conditions stated in the Decision Document(s) resulting from the YESAB Executive Committee screening process, and other issuances, once defined.

1.4.5 Proposed Concurrent Activities

It is anticipated that during each 1 to 3 year timeframe, seismic exploration will alternate with exploration drilling and EFT due to capacity constraints at the camp.

Ongoing Project planning and data analysis will be concurrent with field activities. Chance will engage potentially affected First Nations and residents of communities throughout the life of the Project.

Table 1-3 presents a high-level outline of the timing of main and accessory activities. **Table 1-4** outlines the sequence of well development activities including well pad development, drilling, DST and EFT, and what resources are needed based on the success of drilling and testing.

Table 1-3. Project Activity Timing

Component	Timing	Details (as needed)
Seismic Exploration Program	Except for seismic data recording, the seismic programs will occur during the winter and alternate with the drilling activities due to capacity constraints at the camp.	Subject to this limitation, seismic programs could occur during the 10-year exploration period.
Drilling Exploration Program	Alternating with seismic programs initially, starting during the winter months (October through April).	Drilling may be interspersed with accessory activities such as preparing/decommissioning access to well sites, mobilizing/demobilizing equipment, and reclamation activities.
EFT program	Timing will depend on the exploration drilling results, primarily the discovery of crude oil or natural gas, and the capacity of the 75-person camp to accommodate the necessary crews.	The EFT will be staggered across the Project area, but it is expected that one or more EFTs will occur in the Project area during the winter season, following initial discovery from drilling.
MBC sump pod construction	MBC sump pod construction will occur in every season that drilling is occurring, and pods will be built on an as-needed basis to dispose of drill cuttings.	
Airstrip and CPF construction	Airstrip and CPF construction will likely occur within the first or second winter season.	
Reclamation	Reclamation will be ongoing throughout the Project's life.	

Table 1-4. Sequence of Well Development Activities

Sequence of Well Development Activities	
1. Develop winter access road to well site.	
2. Develop well site (approximately 1.44 ha in area).	
3. Install surface infrastructure for drilling and testing exploratory well on well site.	
4. Drill well.	
5. Transport and dispose of drill cuttings in MBC sump via winter access road.	
6. Well logging and core sampling before conducting DSTs.	
7. Conduct DSTs to determine whether EFT should be conducted.*	
8. Move drill rig to the next well site area.	
If DST is not successful* (i.e., no petroleum products were encountered in the well)	**If DST is successful** (i.e., Natural Gas or Crude Oil is encountered)Successful wells will be suspended as an intermediate step to cover timing differences between finishing the DST and undertaking EFT.

	Abandon well (cement all perforated producing zones, install shallow cement plugs, and cut surface casing 1 m below normal ground surface).	Abandon well (cement all perforated producing zones, install shallow cement plugs, and cut surface casing 1 m below normal ground surface).
	Remove all surface infrastructure.	Remove all surface infrastructure.
	Remediate well site area and allow to regenerate naturally.	Remediate well site area and allow to regenerate naturally.

Note: * DSTs can occur throughout the drilling process and are not delayed waiting for the entire well to be drilled. These tests are done following logging and any core sampling, but prior to casing the well. There may be multiple DSTs performed on a given well as the drilling proceeds, and success or failure of the well is determined based on results of all the DSTs completed.

1.4.6 Project Scale

Spatial boundaries, including local and regional, account for the scale and spatial extent of expected Project activities. The area in which Project activities will take place comprises approximately 2,400 km² of oil and gas exploration rights or permits on either side of the Dempster Highway south and west of the Eagle Plains Hotel. This includes the area of seismic work. This area has been defined as the Regional Study Area (RSA) for the Project Proposal and is further defined and described in **Section 3 Methods**.

Temporal scale accounts for the duration of time of the activity or the effect of the activity. Chance intends to conduct exploratory Project activities over 10 years, possibly beginning as early as 2025, conducting activities primarily during the winter.

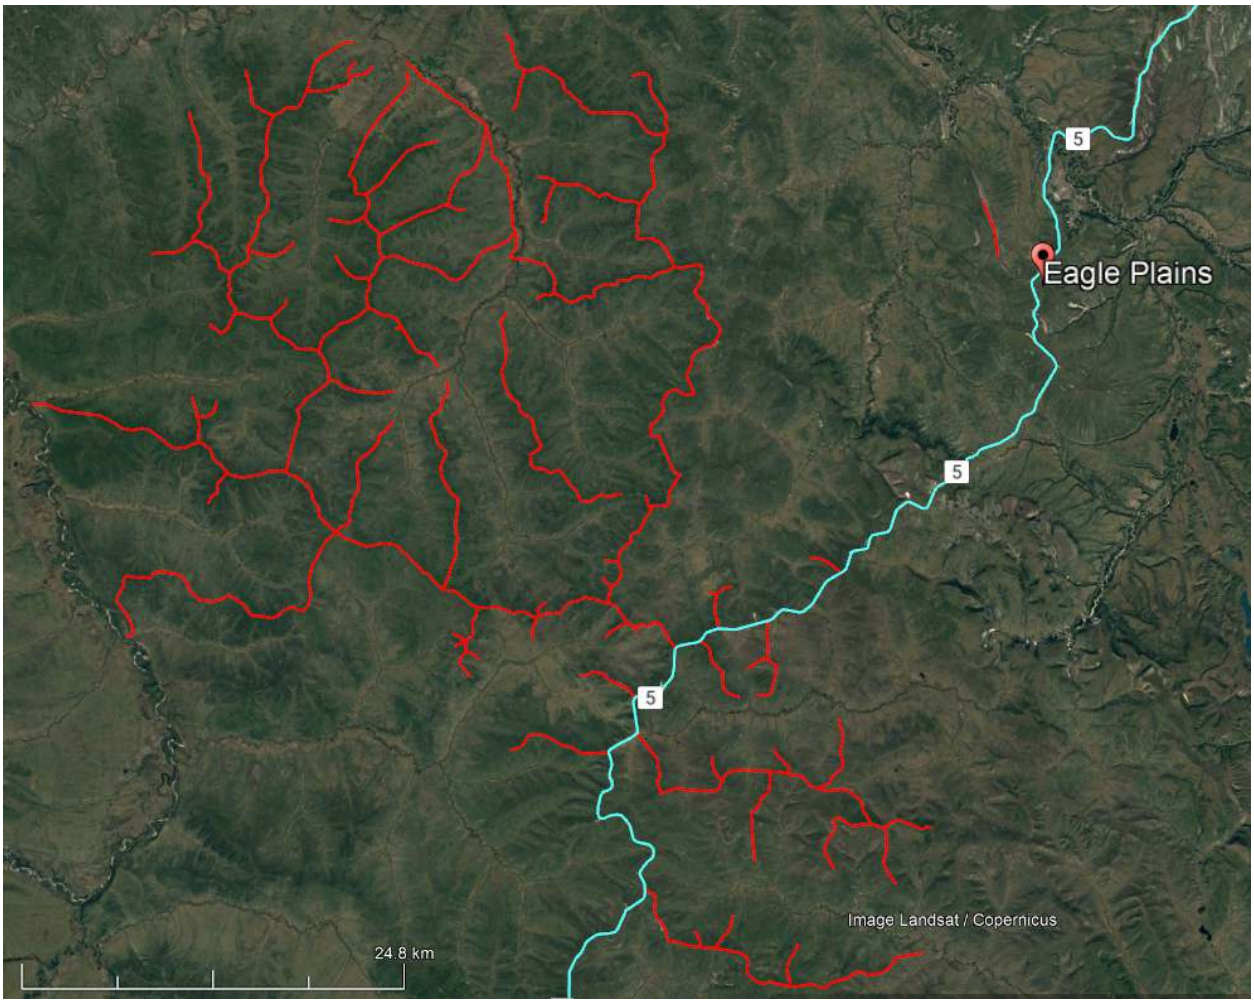
Further details about spatial and temporal boundaries are discussed in **Section 3.1.2.2**.

1.4.7 Access and Transportation

1.4.7.1 Access

Winter roads will be used for the exploration program. No new permanent roads are anticipated within the exploration stage of the Project. **Figure 1-10** shows the maximum potential winter road network to the exploration sites. Each winter road's number, location and length will be determined as the exploration program develops. As the program unfolds, the access road network's size will depend on drilling results (success). If drilling results are discouraging, the road network may be less than shown.

This Project's proposed winter road construction method will be a compaction of the natural snow cover. Water may be needed in some areas to reinforce the packed snow. Some snow may be hauled to low areas or areas that are wind-blown. The natural vegetation cover will be preserved and remain undisturbed as much as possible. Compacted snow roads are appropriate to serve low ground pressure geotechnical field programs or winter roads with low traffic volumes. This method will suit this exploration program, as the expected traffic on this road will include transportation of a drilling rig with anticipated one to two moves (this number could be up to five depending on the time needed to drill and evaluate a given well) per season, and a small number of support vehicles. Winter roads will be restricted from public access for safety reasons.



Note: Roads on this map only include primary winter road access network. Proposed spur roads to well sites are not shown.

Figure 1-10. Conceptual Winter Road Network

1.4.7.1.1 Routing Rationale for the Winter Roads

The routing of a winter road needs to consider the following criteria (discussed in detail below):

- road geometry, such as grades and curves to suit the intended vehicles;
- number and width of water crossings;
- avoidance of unfavorable terrain;
- avoidance of selected areas determined by historical resources, vegetation, and wildlife habitat; and,
- sensitivity of permafrost terrain.

Road geometry: Ideally, for vehicle safety, the maximum gradients on the road should be 6% or less, with only short sections up to 10%. The routing developed for this Project generally falls within this range, although route adjustments will likely be undertaken in the field if these desirable gradients are met.

Number and width of water crossings: Selecting routes that minimize the number and width of water crossings reduces the complexity of the winter road construction and the uncertainty or risk during operation. All crossings are expected to be completely frozen during the operating season.

Avoidance of unfavourable terrain: Chance has undertaken terrain mapping of the area. The route is located on bedrock, weathered bedrock and colluvial sediment where possible.

Sensitivity of permafrost terrain to constructing a winter road: Chance has undertaken permafrost mapping in combination with terrain mapping. The route, where possible, is generally located on ice poor to ice-moderate permafrost. Ice-rich permafrost is sensitive to the activities associated with the construction and use of winter roads and will be avoided to the extent possible. Specific mitigation to preserve permafrost will be undertaken when it must be crossed.

The development of the routing for the potential winter road network has considered these criteria. The potential routes have been selected to minimize the effect on unfavourable terrain and thaw sensitive permafrost terrain while balancing the need to access sites.

1.4.7.1.2 Construction Considerations and Operating Season

The winter road will not be constructed until the ground is sufficiently frozen and has adequate snow cover to limit disturbance to the ground and vegetation.

Winter road construction will commence when the depth of snow cover is sufficient to cover low-lying vegetation after compaction (estimated to be greater than 60 cm before packing), thereby minimizing effects on the ground. This can be supplemented by hauling snow from other areas such as the Chance Camp or by utilizing snow-making equipment. The winter road will be constructed with dozers supplemented with steel frame drags. Other equipment may be required to haul snow as necessary.

The winter road widths will be dependent on the size of vehicles to be used each season. Single-lane winter road for smaller lighter equipment and very low traffic volumes will be as narrow as 5 m. Wider two-lane winter roads, approximately 8 to 10 m in width, will be constructed for larger equipment and greater numbers of vehicles.

Closing a winter road is based on observed snow cover depletion and current and forecasted weather. Once the insulating snow softens and disappears and the daily air temperatures rise above 0 degrees Celsius (°C) for a few days, the winter road will be operated only at night, and eventually closed before the ground thaws. Diligent and ongoing observations of the conditions and forecasts will be undertaken so equipment is moved off site and the winter roads are closed appropriately.

The general operating season for a winter road in this area is estimated to be from the end of January to the end of March but could last longer depending on the opening and the end of winter.

1.4.7.1.3 Mix Bury Cover (MBC) Sump Access Road

Chance also proposes the construction of a 400 m long, 6 m wide winter road to the proposed MBC sump area. This road will be built as early in the operating season as possible (soon after mid-January as snow and weather permitting) and will take approximately two weeks to complete. It will be reopened each winter season that drilling occurs. The proposed route follows an existing access road; no major clearing will be

required. The proposed route includes no watercourse crossings and is 800 m from the nearest surface water body.

1.4.7.1.4 Access Road Maintenance

Maintenance of winter access routes may include low-ground-pressure vehicles, a road grader equipped with a wing snow plough, some water application, and use of matting where required. Grading may be required over certain stretches of the route, and depressions along the roads will be filled with snow to smooth the surface. If required, water will be withdrawn from approved water sources using adequately sized intakes and screened to prevent debris blockage and fish mortality; refer to *Interim Code of Practice: End-of-Pipe Fish Protection Screens for Small Water Intakes in Freshwater* (Fisheries and Oceans Canada 2020).

1.4.7.2 Transportation

During the exploration program, Chance will attempt to limit traffic on the winter access roads to authorized personnel.

Transportation of workers, materials, and equipment to the Project will be accomplished using light-weight service trucks, service delivery trucks for fuel and water, and airplane. Personnel will be transported to camp from town using light-weight service trucks or buses or by airplane following the construction of a 1.5 km long winter airstrip at km 4 of the Chance winter road. Personnel and gear will be transported from the camp to well sites via the Dempster Highway and Project winter roads using light-weight service vehicles. Fuel and water will be delivered directly from their respective filling stations to each camp and to well sites as needed.

A typical description of road traffic during the prime operating periods (winter) is presented in **Table 1-5.**

Table 1-5: Typical Road Traffic During Operating Windows

	Activity Description	Peak Traffic	Normal Traffic
1	Early Season Mobilization (Winter)	High	Light /High
2	Rig Mobilization (Winter)	High	Light /High
3	Drilling (Winter)	Light/High	Light
4	Access Road Construction (Winter)	Light/High	Light
5	Extended Flow Testing (Winter)	Light/High	Light
6	Seismic Line Preparation (Winter)	High	Light/Medium
7	Seismic Recording (Summer)	High	Light

Notes:
1. High: 20–40 vehicles per 24-hour day
2. Light: less than 20 vehicles per 24-hour day

Chance expects vehicle volumes on the winter access roads during exploration drilling activities to range between medium and light traffic volumes but may be high temporarily during mobilization of equipment such as the drilling rig. Transportation of supplies, water and fuel trucks will be on demand, as needed. At

a minimum, if required, the essential traffic volume to maintain minimum and safe drilling operations is estimated to be as low as 10 vehicles per day using winter roads to support the drilling operation.

The traffic for the seismic program will primarily be travelling on the Chance and Blackie roads and other proposed winter access trails as well as a small section of the Dempster Highway. The traffic for the line preparation activities in the winter months is estimated to be up to 20 vehicles per day. Any use of the Dempster Highway is scheduled to occur during specific times of the day as crews will be transported to and from their work site at day break, and sundown. The number of vehicles that typically travel the Dempster Highway during winter is 40–50 per day. As this is a very low highway usage time the added traffic for the seismic program is not expected to interfere with regular highway users. The winter line preparation traffic will include mobilization/demobilization and crew transport to and from the main Chance Camp. Using a remote camp will reduce vehicular travel on all roads, including the Dempster Highway, as the proposed remote camp locations are 40 km closer to the seismic program area than the Chance Camp. The traffic of the recording crew is expected to be greatly reduced as helicopters will be used to transport personnel and equipment to the program area rather than vehicular traffic.

Weekly traffic on the Dempster Highway to/from town to the camp, or to/from town directly to the well site may include seven to ten water trucks, two to three fuel trucks, and 10 light-weight service vehicles, each way. Project factors influence transport rates, including weather (more fuel consumed during colder weather), drilling rate (faster penetration requires more water deliveries in a shorter time), winter road water requirements, and well site maintenance. The capacity of the fuel and water haulers, as well as the storage capacity on site is also expected to influence transport rates.

Daily, the Project anticipates using approximately 10 light-weight service trucks to transport supplies and personnel to and from camp to site. During the day, between two and five trucks will be used every 12 hours at shift change to transport personnel to and from camp and the well site. Environmental and wildlife monitors will use two or more additional trucks to conduct their activities.

There will also be occasional transport of drill cuttings from the well sites to the MBC sump area.

Traffic volume on winter access roads is relative to the phase of the drilling program, with highest volumes expected when during drill site mob/demob (e.g. demobilizing a drill site, then mobilizing the drill rig and constructing the site infrastructure) and when setting casing. Inventory management can reduce traffic volumes by sending casing loads in advance of casing activities. Mobilization and drill rig set up takes approximately five days and requires transport of up to 30 loads in 12–24 hours.

Air traffic is estimated at two flights in/out per week to transport workers, materials, and equipment to the Project.

Chance’s contractors will transport crews between the camp and the well site using company vehicles. Vehicles will be equipped with radio communication and, particularly during busy times (i.e., setup and demobilization), will be radio-controlled. For safety reasons, personnel accessing the areas (i.e., winter roads) must notify the appropriate staff (i.e., security personnel or managers/supervisors) when they leave the Dempster Highway and arrive at the well sites. Chance staff or contractors hired as environmental monitors and security personnel will monitor access to the winter roads.

Trucking a stabilized crude oil cargo in specially constructed transporting tanks presents the same risk as transporting the diesel fuel required and used in the Yukon. The process of loading and dispatching trucks

at regular intervals will be planned and handled by licenced professionals who will also maintain constant communication and GPS tracking of trucks travelling down the Dempster Highway and on other connecting routes to their destination.

Chance will employ Journey Management practices during Project activities as part of overall safety management procedures. Any unit transporting materials to Chance's Camp at km 325 will be called and tracked periodically by the dispatcher. This will support road safety for the truck driver and other road users and the safety of the cargo. It also provides critical planning information for receiving staff to plan for offloading its cargo and possibly loading backhauls.

Transportation journeys may include truck delivery to terminals in Fort Nelson and Fort St. John, British Columbia (BC), or Grand Prairie, Alberta. The driving times will vary depending on which of these options is used, but the management procedures will remain the same.

Chance and its trucking contractor(s) will include transportation safety in the Health, Safety and Emergency Response Plan (HS/ERP) to manage potential risks and provide a clear chain of communication and action in the event of an accident while in transit on Yukon roads and highways. The plan will address any other Provincial routes. All reputable trucking contractors versed with transporting flammable liquids and petroleum products generally are mandated to follow the *Transportation of Dangerous Goods Act, 1992, SC 1992, c 34* (Government of Canada 1992). Ensuring the truck is safety-checked and the drivers are qualified and adhere to their company's safety policies are the key to preventing an incident or accident. Tracking the drivers to check on transit speed on a real-time basis means the truck's progress is never neglected and the driver is on notice to observe all road traffic rules at all times.

All incidents affecting Chance's trucking contractor will be reported to Chance and form part of Chance's safety statistics. Each incident will be investigated, and the causes for each occurrence will be closely analyzed and discussed with the truck owner. Should any trucking contractor exhibit an undue number of close calls/near misses or a series of incidents with the same causes, they would be removed from the contract without delay and replaced with a more competent and safety-minded contractor.

1.4.8 Workforce and Accommodation

Workforce requirements will vary over the life of the Project and will ultimately be limited by the existing camp capacity. During past drilling and seismic exploration programs undertaken between 2012 and 2014, the camp had no more than 75 to 80 people on site at any time. During drilling, operations occurred 24 hours per day with a 20-day-on and 10-day-off crew rotation cycle, meaning that one-third of the crew was off duty at any point. The seismic exploration occurred on a 12-hour clock and cycled the various services as the program unfolded with limited crew changes, mostly connected with the camp catering activities.

Chance aims to offer training, employment and contracts to its First Nation/Yukon partners as required in accordance with Section 68 of the Yukon *Oil and Gas Act*, RSY 2002, C.162 (Government of Yukon 2002h) (*YOGA)*. During its last drilling/seismic program, Chance successfully hired a workforce from the communities of Old Crow, Fort McPherson, Dawson, Whitehorse, and Inuvik.

The camp (Chance Camp), office, and storage yard were established in October 2011 and are located at km 325 of the Dempster Highway. The existing 75-person camp will house many workers and be a central location for processing and storage.

The camp is accessible year-round unless the highway is closed due to weather or construction. For this Project, Chance plans to use the camp for storing and transporting equipment and supplies needed for service and personnel accommodations. The Chance Camp is the Project's main accommodation facility, and it can house up to 75 people in trailers alongside a kitchen, sanitary and potable water treating facilities. Camp waste management consists of an incinerator for burning non-toxic and food waste and a secure storage area for other forms of waste. Non-incinerated waste will be transported to an appropriate municipal waste facility for disposal.

Due to the remoteness of seismic activities, a remote camp (fly-in) will be established near the proposed East Greaves and West Greaves Winter Roads, roughly 40 km from the Chance Camp, to accommodate approximately 25 personnel. It would be used as an operations camp with full services, including food, fuel, sleeper trailers, bathrooms, water storage, project management, and HSE offices. The fly-in camp is necessary for activities planned in the winter months due to the cold temperatures approaching - 50°C, the nearly 24-hour darkness, and the potential for "white out" snow storms threatening crew member safety.

In addition, a mobile camp will be established at each active well for onsite accommodation for the rig manager, wellsite geologist and safety/first aid personnel. This will be a trailer accommodating sleeping and a small medical/first aid trailer equipped with heat, power, water, and sewer service that may be installed at the well site during well operations to provide essential first aid supplies and refuge for workers. All wastewater and sewage will be collected in tanks approved by the Canadian Standards Association (CSA) and transported off-site for disposal at an approved facility in Fort McPherson or treated at the Chance Camp.

For the 10-year lifespan of the Project, up to three secondary camps will be established in more remote parts of the area to further support safety and staging of operations. Additional personnel may also be accommodated at the Eagle Plains Hotel if needed.

1.4.9 Project Resource Requirements

1.4.9.1 Water Requirements

The Project proposes the use of up to 300 m³ of water per day (or per permitted limits) for making snow to build winter roads, ice roads and temporary well sites, not exceeding 10% of the instantaneous flow from the following extraction points:

- year-round extraction from the Eagle River, Ogilvie River, and Whitestone River; and,
- seasonal extraction from Glacier Creek.

Water use up to 20 m³ daily (for washing, showers, toilets) is anticipated and bottled drinking water will be supplied to the camp. The majority of water withdrawal is expected to occur in the winter. A water reservoir may be constructed at the camp for water storage and use during low water periods; two insulated water tanks are available for water storage with a capacity of 400 and 700 US barrels (liquid).

1.4.9.2 Chemicals

Chemicals required for the Project may include H_2S Scavenger, clay stabilizers, drilling mud (water- based), weak hydrochloric acid (10–20% concentration) for well acid stimulation, methanol, corrosion additives, demulsifiers, and cement. Specific quantities of chemical usage will depend on the number of wells drilled, as determined by seismic data analysis. Chemicals will be used and stored in compliance with territorial and federal requirements.

1.4.9.3 Explosives

Small dynamite charges for up to 1,500 km^2 of 3D seismic and up to 2,000 km of 2D seismic (using 1 kg per source point) will be required for seismic source points. The specific number of source points required is yet to be determined and will depend on the quantity and quality of the data available. A primary explosives magazine will be required at a staging site near the Chance Camp, and a smaller daily magazine will be required near the specific work area.

1.4.9.4 Fuel Supply and Storage

A fuel storage facility will be required to store diesel, gasoline, propane and Jet-A fuel. Chance Camp will require diesel and propane for on-site power generation, heating and cooking. Diesel will be stored on-site in 15,000 L and 50,000 L Enviro Tanks. There will be up to six tanks at the camp and up to two at the drilling rig site (where the drilling rig is drilling a well). The tanks are bulk fuel, double-walled storage tanks with built-in secondary containment. The drilling rig, boilers, and light towers at the drilling rig site will have built-in fuel storage tanks.

Propane will be used to fuel the furnaces, hot water tanks, and the kitchen at the camp and drilling rig sites and stored in 1,500 L propane bullet tanks. It is anticipated there will be up to six tanks at the camp and up to two at the drilling rig camp. Fuel for seismic activities will be contained at the main camp in double-walled tanks and transported to staging sites in a tank trailer for use. The seismic equipment is expected to use a combination of gasoline and diesel depending on the machine. Additional fuel including diesel, propane and gasoline will be required in smaller quantities for the remote camp and secondary camps.

1.4.9.5 Equipment and Machinery

The Project will require equipment and machinery for each Project component including seismic activities, drilling, EFT activities, well maintenance (workovers), construction of access roads, construction and operation of the MBC sump, construction and use of the CPF, construction and use of the airstrip, use of the camps, and reclamation and closure activities.

Trailers will be required for offices, First Aid, rig crew sleeping quarters, water storage and treatment, sewage storage, and the food waste incinerator.

Anticipated resources required for Project activities are also described in **Section 1.4** and the sequence of well development activities based on the success of DST, EFT and primary type of hydrocarbon discovery was presented in **Table 1-4** and includes a list of key Project components for each exploration activity scenario for further clarity. A more refined list of required resources for each Project component will be prepared after further Project development.

The list of required equipment and machinery for the Project components will likely include, but not be limited to:

- artificial lift systems;
- ATV and snowmobiles;
- battery truck;
- blowout preventor accumulator system;
- boilers;
- canvas tents;
- casing;
- Challenger Cats, D6 cats, snow cats and graders;
- dehydrators;
- double-walled storage tanks for drilling mud, cement, crude oil and formation water;
- drags;
- drilling mud tanks, pumps and mud mixing and separation systems;
- drilling pipe (e.g., conductor, casing, production, liner);
- drilling rig
- flare tank and flare stack;
- flatbed trailers;
- flow lines and valves;
- heaters;
- helicopter & fuel tanker;
- LIS tracked seismic air drilling units;
- explosive magazines;
- medivac units;
- metering equipment;
- mulchers and mulching equipment;
- multi-stage and multi-phase separators;
- packer, tubing and gauges;
- picker trucks (1-ton trucks with equipment);
- portable generators;
- power generators;
- rig matting;
- seacans and storage bins for storage and tools;
- seismic recording equipment;
- separator and treating vessels and storage tanks;
- snow-making equipment;
- vapour and gas collection system;
- vehicles/trucks (1/2, 3/4, and 1 ton);
- waste bins;
- wastewater and sewage tanks;
- water trucks; and,
- wellhead valve assembly.

1.4.10 Project Emissions, Discharge of Wastes, and Disturbances

1.4.10.1 Project Emissions

Please refer to **Section 1.9 Air and Greenhouse Gas (GHG) Emissions**.

1.4.10.2 Waste Discharge

Sources of waste at the Project include domestic and sewage waste at the camps, and drilling waste at the well sites. The main waste discharge from the Project is anticipated to be drilling waste produced at the well sites.

Discharge of wastes will be managed following applicable territorial and federal legislation. Where feasible, Project design will incorporate features to enhance efficiency, reduce waste, and minimize general effects on the surrounding environment.

1.4.10.2.1 Seismic

There is no waste discharge associated with the seismic program. Waste is limited to garbage generated on site. Once the program is complete, a crew may be deployed to clean up any remaining material used on the lines for the seismic program. The garbage is returned to a staging point and discarded in an approved bin to be transported to an approved waste facility.

1.4.10.2.2 Camp

At the Chance Camp, waste management consists of an incinerator for burning non-toxic and food waste and a secure storage area for other forms of waste. Incineration will generate discharges to air, which are discussed in **Section 1.9**. All non-incinerated waste will be transported to an appropriate municipal waste facility for disposal.

Bottled water will be provided for human consumption. Wastewater disposal at the Chance Camp consists of a wastewater treatment plant, a holding lagoon, and an exfiltration system.

For other remote and mobile camps, wastewater and sewage will be collected in tanks approved by the CSA and transported off site for disposal at an approved facility in Fort McPherson or Yukon Lagoon at km 4 on the Dempster Highway.

1.4.10.2.3 Well Sites

At each well site during drilling, there will be sewage storage, and a food waste incinerator related to the operation of the related camp accommodation. There is no discharge of wastewater or sewage as they will be collected in tanks.

Waste discharge at well sites during drilling will comprise drilling waste that includes rock chips and cuttings. The drilling fluid returned to the surface is sent through a shale shaker to separate rock cuttings, and the drilling mud is returned to the well to continue drilling. The recovered cuttings are put through a centrifuge, where the drill cuttings are further separated from any residual water before being disposed of in the MBC sump. At the end of drilling, the mud slurry is run through the centrifuge to separate the water for future use in the next well. Recovered mud is disposed of in the MBC sump.

Chance has selected well site dimensions to provide an appropriate perimeter for containing liquid or solid waste from the Project. The well site will be lined to contain potentially released fluids.

The Oil and Gas Branch of the Yukon Government has adopted *Directive 050: Drilling Waste Management* (AER 2023) procedures for the disposal of drilling wastes within the Yukon. Chance will follow the MBC requirements of the Directive for the remote sump locations.

1.4.10.2.3.1 Solid Drill Cuttings

Drill cuttings are a direct byproduct of the drill bit grinding through rock. Cuttings are brought to surface with the drilling mud and separated via shale shakers and centrifuges.

“Stripping” is running the drilling mud through centrifuges as it returns to the surface to separate the water from any solids suspended in the fluid stream. Cuttings are separated during stripping and stored separately on the well site until they can be disposed of. The fluid is then either recycled back into the mud system in the drilling operation or retained for use in future drilling locations.

Close attention to the dryness of the cuttings moving across the shale shakers and collected in the shale bins is required for the following reasons:

- Less total weight in the cuttings equals less cost associated with future handling of the drill cuttings.
- In the winter, handling and moving dry cuttings is easier as they do not freeze and create large blocks of material.
- Recycling more fluid separated from the cuttings reduces the need for additional make-up drilling fluid.

Drill cuttings will be removed from the well sites for disposal at the MBC sump.

1.4.10.2.3.2 Drilling Mud

Chance is proposing to use water-based drilling fluid systems. After drilling a few wells using recycled drilling fluids, the mud system may need to be partially or fully reconstituted (disposal of the current fluid and mixing fresh water and new drilling fluid products). This ensures the drilling fluid is fresh and capable of drilling through the different rock types found in the proposed wells and is performing to meet exploration needs. Chance has successfully re-used drilling fluid systems across multiple wells to reduce the overall need for make-up water and the total fluid volume for disposal.

The following conditions were established for the selection of the drilling mud system:

- low-toxicity mud system confirmed through laboratory analysis;
- meets program requirements (maintain formation stability, hole cleaning and well control); and,
- suitable for disposal at the MBC sump.

Any drill fluid selected must satisfy Section 32 "*Approved Drilling Fluid"* of YOGA's *OGDPR* (Government of Yukon 2004).

1.4.10.2.4 Mix Bury Cover (MBC) Sump

As described and detailed in *Directive 050 Drilling Waste Management* Section 13 (AER 2023), and accepted in the Yukon, MBC is a method of disposing of drilling waste (both drill cuttings and drilling mud) by which the byproducts and spent mud are mixed with a local receiving soil at a specific mix ratio, deposited into a sump area, and then covered with clean subsoil.

A typical MBC sump design consists of three distinct layers:

- A clean subsoil layer 1 to 1.5 m deep on top of the drill cuttings and soil mix acts as an insulator between the subsoil/drill cutting mix and the vegetative layer to support that, after final reclamation, the site is returned to its original state.
- The subsoil/drill cutting mix layer is where the receiving subsoil is mixed at a specified mix ratio with the disposed of material (e.g., drill cuttings, spent drilling mud).
- Clay-rich material exceeding 1 m depth below the drill cuttings and soil mix, or alternative impermeable liner, acts as a hydraulic isolator.

The identified MBC sump location will be investigated for suitability via drill cores to confirm the following conditions are present and at what depth:

- Sump soil has appropriate deposits of clay-rich soils.
- Appropriate clay-rich material of 1 m is beyond the horizontal and vertical dimensions of the sump for hydraulic containment.
- There is an absence of hydraulic defects or ways for fluid to leak out of the sump.
- A composite sample, made up of five subsamples, is required for every 3,000 m³ proposed to be used for MBC.

Before Project-related drilling activities begin, a test sample of the drilling fluid will be analyzed and compared against the receiving soils at the proposed MBC site to estimate the soil/waste mix ratio to determine if the final soil composition complies with *Directive 050 Drilling Waste Management* Section 3 (AER 2023). While the MBC sump is actively being used, Chance will monitor and inspect the site to evaluate sump integrity, the volumes of material involved, and if further work is needed to the sump location. Project drill cuttings will be transported to and disposed of at the MBC sump, while drill fluids will be reused until the end of the Project or the end of the season. Chance plans to construct a new MBC sump (see **Figure 1-4**). The preferred MBC location for this Project is an undisturbed area of approximately 63,910 m², adjacent to the historic Devon sump accessed at km 336 of the Dempster Highway.

Figure 1-11 shows the proposed MBC sump area with conceptual MBC pods. Each conceptual pod is 800 m², representing the estimated area required to dispose of 300 m³ of drill cuttings (approximately one well worth). The additional area between and around the MBC pods is to accommodate spacing between MBC pods for truck access and to stockpile excavated material. Chance will operate one MBC pod at a time to minimize potential permafrost exposure to ambient air temperature.

As per the AER directive, sampling drill waste will undergo the following sampling procedures:

- During drilling, the environmental monitor will be onsite to conduct sampling in compliance with *Directive 050 Drilling Waste Management* (AER 2023) to verify that the drilling waste is compliant and accurate records are being kept, and to respond to spills.
- The environmental monitor will take soil samples at the MBC site before use for MBC and after closure and reclamation.

If drilling byproducts do not meet *Directive 050 Drilling Waste Management* (AER 2023), the disposal materials will be transported to an appropriately permitted facility for disposal. Chance has previously used permitted facilities that can accept specified waste, located in Whitehorse and northeast BC.

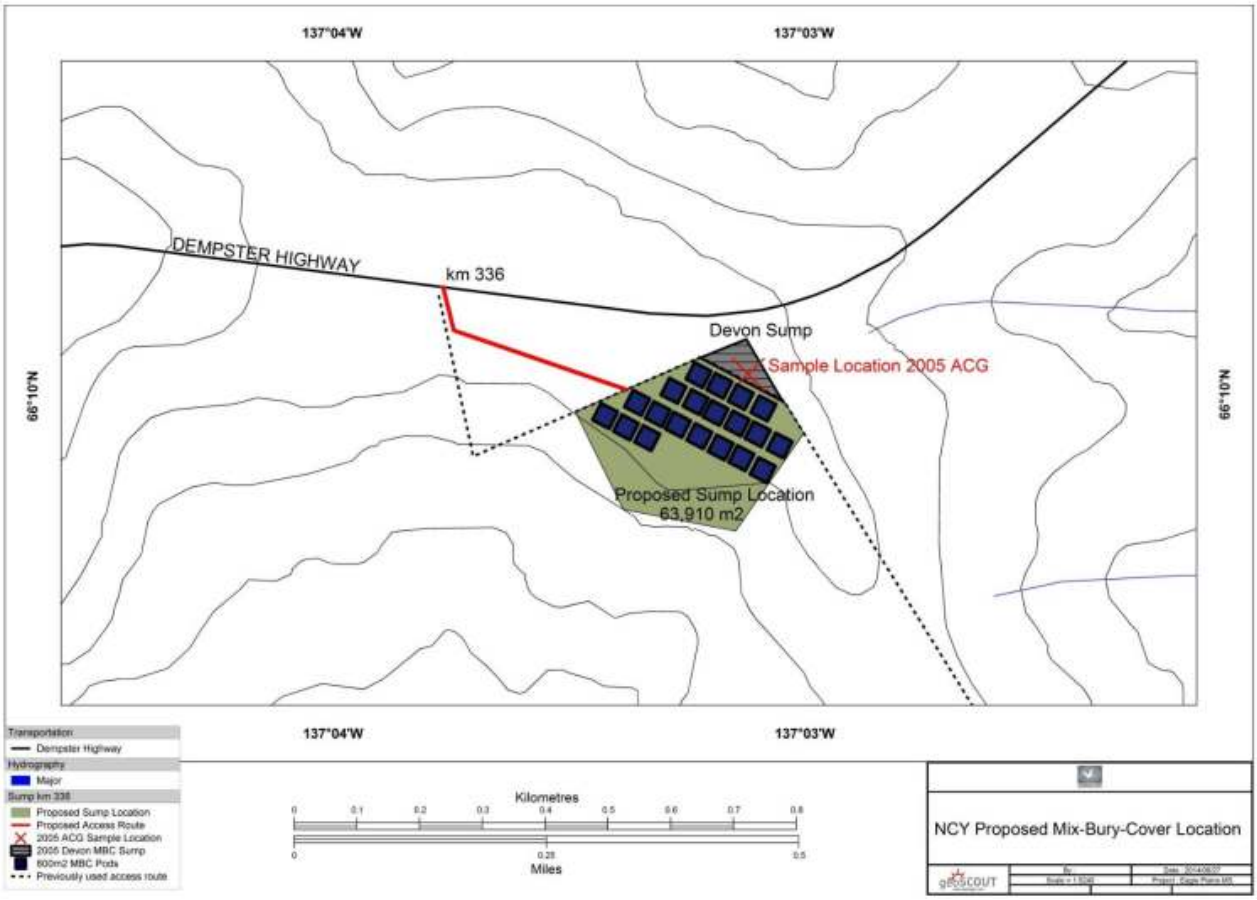


Figure 1-11. General Location and Plan of the Proposed Mix Bury Cover (MBC) Sump

1.4.10.2.5 Injection Well

An active injection well may be used for disposal of waste liquid at depths that are unlikely to affect groundwater and are isolated from surface access by impermeable layers of bedrock, permafrost or other geologic layers. Active injection wells can be converted back to suspended status but cannot be used as production wells without refitting; injection wells do not produce oil or gas products. Existing (historic), suspended wells, or wells drilled as part of the Project will be converted into injection wells for disposal of fluids including produced water, drilling fluids, and rig wash. Produced water refers to water (e.g., formation water) that returns to the surface as a wastewater byproduct when oil and natural gas are extracted. Chance has two wells already screened and are pending permitting for deep zone disposal; they are existing suspended wells A-25 and E-78. It is likely that one or both of these wells will be used for disposal/injection.

Directive 050 Drilling Waste Management (AER 2023) covers the disposal of drilling fluids. Drilling fluid will be stripped back to the clear portion and disposed of in an approved injection well. Disposal of production fluids will meet the environmental standards as well the oilfield waste disposal standards and limits per the relevant Sections in YOGA *OGDPR* (Government of Yukon 2004).

Injection wells require injectivity and suitability investigations before approval and use. This cannot occur until the wells are re-entered and ready for the investigation trials. As such, injection well locations were not confirmed at the time of Project proposal development. Injection well testing and suitability investigations will be in compliance with the applicable legislation including:

- the zone within which injection is proposed must have an impermeable barrier above it to prevent migration of the injected fluid;
- the zone within which injection is proposed must be greater than 750 m below the ground surface;
- within the proposed injection zone, the rock's permeability and porosity must permit fluid pumping at low surface pressure and well below formation breakdown pressure;
- testing must determine injection fluid compatibility between the rock and native reservoir before injection; and,
- testing must determine the porosity and permeability of the formation and reservoir by measuring the pressure and rate of injection.

Once their disposal suitability is confirmed, the following types of liquid materials (treated with bactericide) will be disposed of within injection wells following Project permits/licences:

- produced water per well;
- workover fluids;
- rig wash;
- saline fluids (completion brines); and,
- liquid fraction of drilling fluids.

To support best reservoir management practices, the re-injection of produced water back downhole may sometimes be required.

1.4.10.3 Disturbances

Seismic exploration will occur across an area of up to 1,500 km² (2.75 m wide source lines, 1.75 m wide receiver lines all mulched) for 3D seismic, and up to 2,000 km (2.75 m wide) for 2D seismic. To minimize surface disturbance, the line preparation (access road construction, line cutting, surveying, and drilling) will be conducted during the winter months (potentially starting in October but likely December through April) under frozen ground conditions, and recording would then follow in the summer months (July through September). Existing disturbances including previous cut lines, burn areas, and natural open areas will be used, where possible. The calculated disturbed area from seismic exploration over the life of the Project is estimated to be approximately 6,336 hectares (ha).

Each season, a maximum of 125 km of new winter access roads will be created. This will require clearing woody vegetation above the surface of the snow for the length of the route. The roads will be 8–10 m wide with 16–20 m pullouts every 5 km. Approximately 15% of the roads will be built on previously disturbed ground such as old roads and cutlines. A maximum of 200 km of winter access roads (new winter access + previously cleared winter access) will be active each season. To minimize disturbance, the winter road will not be constructed until the ground is sufficiently frozen and has adequate snow cover to limit ground and vegetation disruption. Existing shrub-stage vegetation will be pushed over or cut as high as possible. Access to winter roads will be restricted during and after exploration, allowing the road to fully melt in spring,

thus reducing the potential for additional disturbance caused by outside users. Over the life of the Project, approximately 563 ha of area will be disturbed for winter access roads.

Each well site is approximately 1.44 ha. Total disturbance due to Project well sites is anticipated to be a maximum of 43.2 ha if all 30 wells are drilled. To minimize disturbance, trees and shrubs are cleared but ground vegetation left intact. Where trees and large shrubs exist, they will be hand cut and piled to form brush piles for later use in the site's reclamation. The sites are levelled using a minimum of 10 cm packed snow or ice, and rig matting provides insulation and protection to the underlying snow and ground surface.

The MBC sump area is planned to be approximately 6.4 ha total. Each MBC "pod" will be 800 m² and contain the drill cuttings from one well; only one pod at a time will be active/excavated. The preferred MBC sump location for this Project is located adjacent to the historic Devon sump accessed at km 336 of the Dempster Highway.

The Chance Camp, including the CPF and all other proposed camp infrastructure, is located within an existing disturbed area, approximately 9 ha in size. No additional surface disturbance is expected in this area, beyond historically disturbed to construct the camp.

The airstrip will create a disturbance consisting of a 1,500 m long runway with associated aviation fuel storage. Approximately 6.8 ha will be disturbed as part of constructing the airstrip.

Surface disturbances will be mitigated using measures and best management practices (BMPs) recommended by the NYLUP and PWLUP. All disturbances will be subject to the Reclamation and Closure Plan measures, including progressive decommissioning and reclamation of areas when no longer required for the Project.

Noise and light disturbances are discussed in the context of potential disturbances to receptors, and as such are discussed in **Sections 4-11** of the Project Proposal as applicable.

1.4.11 Third-Party Project Activities

Third-party activities and contractor/subcontractor support that are anticipated for the Project may include, but not be limited to, the following contractors, subcontractors, supply services and vendors:

- drilling and engineering consultants;
- environmental and regulatory consultants;
- consultation and engagement consultants;
- environmental monitoring support (e.g., wildlife monitors);
- seismic exploration activities and data analysis support;
- construction contractors (e.g., road maintenance, equipment maintenance, vegetation clearing, well pad construction, reclamation and closure activities);
- safety contractors;
- camp contractors (e.g., camp catering, housing services, waste and sewage management);
- laboratory testing and analysis;
- logistics support (e.g., logistics services, equipment delivery, power, communications);
- transportation services (e.g., bus transport, hauling, flight operations); and,
- vendor support (e.g., material suppliers).

1.4.12 Project Alternatives

1.4.12.1 Seismic Alternatives Assessment

An alternatives assessment was conducted to determine the most appropriate methodology for collecting geological information for the Eagle Plains region. Many factors including the quality and quantity of existing data and the feasibility and accessibility of methods used to acquire new data were considered.

The initial phase was to analyze the existing 2D seismic data, well logs, and geological assessments currently available in the Eagle Plains basin. Although valuable, this information has been encouraging yet deemed insufficient to adequately develop a comprehensive exploration drilling program. The analysis of the 3D seismic data, conducted in 2014, offered greater detail and provided a comprehensive image of the geology within its footprint. The methodology used for the 3D design and program execution of the 2014 seismic exploration project revolved around minimizing surface disturbance while maximizing vegetation regeneration capabilities. The same process was used in developing the proposed seismic program for the Project.

The second phase of the alternatives assessment was to analyze the feasibility and accessibility considerations to execute an exploration program in Eagle Plains. The remoteness and terrain are key factors in assessing the feasibility of the different seismic acquisition methods. The difficult terrain eliminates some forms of exploration as the steep slopes and wooded areas adversely affect accessibility to most areas in Eagle Plains. In addition, the short daylight hours in the winter months limit the type of equipment that can be used for winter activities as visibility is limited and safety becomes a growing concern. The Permit Area is deep in Northern Yukon where the availability of equipment and qualified seismic personnel is limited or non-existent. This requires that all mobilization activities are carefully considered to verify that the plan is most appropriate for the Project. All equipment options were considered in developing this exploration plan and the analysis of alternative options are detailed below.

1.4.12.1.1 2D vs 3D Seismic Acquisition

Most exploration within the Eagle Plains Basin is the legacy 2D lines that exist from the 1960s to the early 2000s. The legacy lines within the Eagle Plains region used “cat cut” methods where a wide, straight line was stripped to provide accessibility for the seismic acquisition. 2D only refers to the line having a two-dimensional subsurface view and not the surface methods used to construct the line. The modern Low Impact Seismic (LIS) used today on both 2D and 3D programs has a greatly reduced footprint. It is less perceptible on the ground and from the air compared to the line construction method used on the legacy lines. The effect and regeneration review of the 2014 seismic program was a testament to using these LIS methods in Eagle Plains, as this was the first ever LIS 3D seismic program conducted in the region.

2D seismic acquisition is best for initial analysis of a formation to reduce the time and cost of acquiring the more detailed 3D seismic program. This type of exploration is better suited to image large structures as much of the geology between lines requires interpolation of the continuation of the stratigraphic features. This can help determine the closing of a stratigraphic feature. Both 2D and 3D methods will be used in the Eagle Plains area to image the basin’s complex geography and delineate the edges of the hydrocarbon resource.

1.4.12.1.2 Vibroseis

Vibroseis is an alternative to drilling shot points (i.e., the standard approach for seismic testing) and instead uses a “vibrator truck” to create the energy source. This is done by lowering a large plate onto the ground that vibrates at a specific frequency to produce strata penetrating sound waves. These sound waves are then recorded using geophones placed into the ground in the same fashion as a traditional shot point program.

The draw back to this technology is that the units are very large. Source lines need to be cleared to a much wider width of 6–8 m. In areas where the units would be required to turn around, such as at the intersection of the source line with a creek, there would be additional clearing requirements to provide enough room to maneuver. As Eagle Plains also has many 15–20 degree slopes, these units would require the additional support of a “tow cat” to aid the vibrator in ascending and descending the steep slopes. Another drawback of using the vibrators is that the seismic program must be conducted completely in the winter months. There is no flexibility to prepare the source point locations in winter and conduct the program recording in the summer.

1.4.12.1.3 Heli-Drilling

A heli-drill is a portable unit deployed by a helicopter from hole to hole that could be an alternative to the tracked air hammer drill rig for drilling of seismic shot holes. These units are long lined into position where a drilling crew waits at the surface. These drills require a helicopter pilot skilled in long lining as a helicopter is required to move each drill from hole to hole.

The size of the proposed seismic program would require multiple drilling units and several helicopters due to the volume of source holes. This poses several problems, primarily the availability of units and the safety of field personnel. The number of heli-portable drilling units available is limited as this technology is seldom used for seismic exploration and is time-intensive to deploy and cost-prohibitive.

Heli-portable exploration requires long hours of daylight, making winter work impractical due to the extended periods of darkness in the Northern Yukon. In addition to increased noise, safety is an additional concern with heli-portable use due to the increased number of helicopters in the area, the exposure of pilots to potential collision, and all ground crew to overhead hazards.

1.4.12.1.4 Hand Drilling

Hand drilling uses a short-stemmed auger drill that is typically manned by two crew members and could be an alternative to the tracked air hammer drill rig for drilling seismic shot holes. This type of drill in not mounted on a stabilization unit and is more challenging and dangerous to operate. Although this method is used in areas with access restrictions, it is limited in the number of holes that can be drilled, it poses more safety concerns, and the holes are shallower than any other forms of drilling.

As hand drilling requires the downward pressure of the two person operators, it is impossible to drill in areas with hard soils or permafrost. The operators are also closer to the exposed drill bit, increasing safety concerns. In addition, this technique is limited in the depth of the hole that can be drilled. This reduced depth would not be adequate to load a large enough charge with sufficient energy to obtain optimal records to image the subsurface layers at the targeted depth. When utilizing hand drilling, the shot point is drilled in

a muti-hole pattern with a reduced charge in each hole to compensate for the lack of charge that can be loaded at the shallow depth, resulting in triple the holes being drilled.

1.4.12.1.5 LIS Methodology

After review of the available seismic exploration methods and the effects assessment of the past seismic activity in the Eagle Plains area, it was deemed that the LIS methodology used to conduct the 2014 2D and 3D seismic programs is the preferred method for the Project. This method maximizes the quality of data collected while minimizing the effect on the environment by reducing the footprint and reducing the potential for safety incidents. Although this method is currently the best available option, new technologies will be reviewed as they become available and assessed for technological adequacy, environmental effects and safety of use.

1.4.12.2 Drilling and Extended Flow Testing Alternatives Assessment

Alternative technologies and methods for oil and gas exploration drilling and potential subsequent EFT for oil and gas extraction are not currently available. EFT will only be conducted on wells where petroleum products were encountered to gather information about the nature of the petroleum resource accumulation and its productive capability. Project activities follow current industry best practices and Government of Yukon standards. Conducting the drilling programs in the winter is expected to minimize terrain, terrestrial and aquatic environmental effects. Where appropriate, opportunities to eliminate or reduce flaring from any residual solution gas not consumed for process heating or engine power will be evaluated following the Yukon *Guidelines: Flaring, Venting Reduction, and Fugitive Emissions* (Government of Yukon 2019). Technologies and practices related to oil and gas flaring are evolving and will be reviewed by Chance as they become available.

1.4.12.3 Project Location Alternatives Assessment

Alternative locations for the proposed Project were considered. However, the proposed Project has been sited within the Eagle Plains sedimentary basin which contains proven natural gas and oil reserves (Government of Yukon 2019), including 4.6 billion cubic metres (m^3) of gas and 3.2 million m^3 of oil (Hannigan 2014). The Project area has had intermittent periods of oil and gas exploration since the 1950s. That activity has established winter roads, exploratory well sites, worker camp, and other infrastructure in the area that can be used during Project activities and produced available historical oil and gas data for evaluation to improve the success of a viable hydrocarbon discovery as a result of this Project.

The Project is located within the North Yukon Planning Region and Peel Watershed Planning Region and is therefore subject to the approved *North Yukon Regional Land Use Plan* (NYRLUP) (Vuntut Gwitchin Government and Yukon Government 2009) and the *Peel Watershed Regional Land Use Plan* (PWRLUP) (Peel Watershed Planning Commission 2019). Within both plans, the Project is within a designated Zone IV integrated management area which allows for the highest development level to occur, in comparison to Zone I through Zone III integrated management areas which are classified as having higher sensitivity to landscape disturbance, ecological and cultural values, risk of significant adverse effects, and level of acceptable change.

1.4.13 Proposed Project Benefits

Benefits for any oil and gas activity in the Yukon is a requirement under Section 68 of the *YOGA*. The *YOGA* generally prescribes opportunities to be offered for employment, training and contracting for services and goods for Yukon First Nations, its citizens, residents of communities affected by the oil and gas activity, and other Yukon residents. Potential Project benefits related to employment, economy, and community infrastructure and services have been identified in **Section 11 Socio-Economics** and summarized in a more generalized manner below for this section.

1.4.13.1 Energy Security

The Yukon has unique energy challenges including long distances from production centres, high demand for heat during cold winters, and an isolated electricity grid (Government of Yukon 2020). The Project proposes to explore a local/regional oil and gas source for the Yukon, ultimately providing longer term benefits by lowering the carbon footprint on fuel consumption and greenhouse gas emissions should the Project be successful.

1.4.13.2 Employment and Economy

There are potential beneficial effects on local/regional employment and contracting opportunities from Project demands on local/regional labour resources and third-party services. Given the exploratory nature of the Project, such opportunities are expected to be relatively small scale over the 10-year lifespan of the Project and be primarily related to winter Project activities. It is anticipated there may be employment opportunities hired from the northern Yukon region and Northwest Territories related to camp operations, logistics, winter road and well site construction and maintenance, wildlife and environmental monitoring, some services and labour opportunities for the drilling and testing activities, and some services and labour opportunities for seismic exploration.

The oilfield services required to undertake seismic, drilling, and extended flow testing activities are generally specialized and of limited availability in the Yukon. These services are generally imported from supply centres in Alberta and BC. Some limited employment opportunities for First Nation/Yukon partners may be available with these service providers.

Employment with supporting services such as camp catering, transport for crew changes, water (e.g., for camp use, drilling, snow making, road and well site construction) and waste hauling (e.g., produced water disposal, sewage transport from the remote camp back to the main camp), freight hauling, and rig transport may be available for First Nation/NWT/Yukon partners.

This Project may offer economic diversification and economic activity during a typically quiet period (winter months). The Project is small in scale and may foster conditions that allow local businesses to participate and develop expertise in new areas.

The capital spending of the Project may cause an indirect economic benefit in terms of income taxes paid by Yukon citizens and businesses participating in the Project. Depending on the activity, annual capital spending in Canadian dollars (CDN$) is estimated to range between CDN$15 and CDN$35 million per year for this Project.

1.4.13.3 Training Programs

There is potential for some beneficial effects for education services available within communities to offer specific training to First Nation/NWT/Yukon partners to support local residents meeting the requirements. The proposed Project is situated in a northern, remote area and personnel exposure to typical safety hazards associated with oil and gas industry operations are possible (e.g., high pressures, heavy machinery, hot fluids, flammable fluids, chemicals, explosive materials, extreme weather); therefore, training programs are planned to provide appropriate personnel with safety knowledge and a safe working environment. Examples of training will include Bear Aware, First Aid, H_2S Aware and H_2S Alive, Workplace Hazardous Materials Information System (WHMIS), Transportation of Dangerous Goods (TDG), Common Safety Orientation, Fall Protection, and other relevant workplace safety training as applicable. Training may be available for wildlife and environmental monitor positions.

1.4.13.4 Future Project Benefits

Should the exploration Project be successful, the benefits may expand to accommodate investment interest in infrastructure associated with a potential future development, if approved. The economic benefits of a potential longer-term oil and gas development (e.g., taxes and royalties, energy supply, employment and training) will be greater than can be offered during this early-stage exploration Project.

Chance is committed to ongoing consultation and discussions around potential Project benefits and associated Benefits Agreements, following Section 68 of the *YOGA*, including training, employment, and contracting opportunities with potentially affected First Nations.

1.5 RECLAMATION AND CLOSURE

Progressive reclamation and closure activities are planned to be ongoing during the exploration program. This includes the reclamation of winter roads, abandoned well pads, seismic lines, and clearings due to accessory activities. As this Project primarily involves winter activities (except for seismic recording), reclamation will mostly rely on low impact seismic, stem bending, and natural regeneration, intended to minimize ground surface disturbance. A Conceptual Reclamation and Closure Plan will detail reclamation, abandonment, and closure activities. A summary of reclamation and closure activities are outlined in **Table 1-6** with some of the key activities described in the following subsections.

Table 1-6. Summary of Key Reclamation and Closure Activities

Project Activity	Activity Description
Engagement	ongoing engagement with First Nations.
	ongoing engagement with community residents.
Seismic Lines	LIS, narrow construction, stem bending, natural regeneration
Well Suspension	Wells that have successfully undergone EFT will be suspended pending future development approval.
Well Abandonment	Unsuccessful wells and wells not used for disposal will be abandoned when testing or production phases are complete.
	Testing facilities are to be removed from each site.

Project Activity	Activity Description
Mix Bury Cover (MBC) Sump Site Reclamation	The site will be reclaimed as per *Directive 050 Drilling Waste Management* (AER 2023)
Central Processing Facility (CPF)	Upon completion of field decommissioning activities, the CPF will be removed.
Well Site Reclamation	Well site equipment will be removed.
	Area will be allowed to revegetate naturally.
Accessory Activities	Discussions with regulators (as necessary) before reclamation work to determine whether there should be changes to the plan
	Annual monitoring until vegetation regrowth is deemed satisfactory
	Conduct a Phase 1 Environmental Site Assessment (ESA) for each location.
	Obtain Regulatory Closure approval.

1.5.1 Seismic Lines

In addition to the low impact seismic method, with reduced line width and meandering paths, the remediation plan will include access deterrence. Although nominal, standing timber will be gently pushed across seismic lines to create a Leaning Tree Stand (LTS) using a “Stem Bending” method to decrease these sight lines. Although not expected to be required to a great extent in the Eagle Plains area, this technique is highly effective in reducing access and enabling sufficient cover for vegetation regeneration.

1.5.2 Mix Bury Cover (MBC) Sump Site Reclamation

The standard *Directive 050 Drilling Waste Management* (AER 2023) of action prescribes the following closure and reclamation actions for MBC sumps:

- Upon completion of the Project, remote disposal locations will be covered with a minimum of 1.0 m of capping material and contoured to meet background topography.
- A Phase 1 ESA will be completed for each well and corresponding remote MBC location to identify any potential areas of environmental concern.
- If the Phase 1 ESA triggers a Phase 2 ESA, soil samples will be collected and analyzed at an accredited laboratory.
- If contamination is identified, a Remediation Action Plan will be prepared and upon approval, the remedial program will be completed. Once all contamination is addressed in the Phase 1 ESA, Phase 2 ESA, or Remediation, a surface program will be conducted, including soil and vegetation.
- Once vegetation is established, a Detailed Site Assessment will be completed comparing soil lithology and vegetation on site to off site.

The stockpiled vegetative layer and soil will be re-applied to the MBC sump area on top of the capping materials and after completed contouring. Environmental monitors will follow the testing requirements following *Directive 050 Drilling Waste Management* (AER 2023).

1.5.3 Well Abandonment

As mentioned, the 30 proposed wells are part of an exploration program to help determine the region's oil and natural gas resource potential. Depending on the outcome of the results, some wells may be proposed for future production as part of a separate project, to be evaluated and assessed at that time based on relevant regulatory pathways. All other, unproductive wells will be decommissioned and abandoned. As the Operator, Chance is responsible for all wells deemed its property. This responsibility can never be delegated to any other party unless and until such time Chance relinquishes ownership according to *YOGA* and its regulations (Government of Yukon 2002, 2004).

Wells maintained for potential, future production or other operational uses will be suspended for future conversion to those uses. The *OGPDR* under *YOGA* (Government of Yukon 2004) have specific actions required from an operator to maintain a well in a suspended state; key among these actions is to periodically conduct inspections to verify that the integrity of the well is intact. While a well is in suspended status, the regulator requires a sum of money to be placed on deposit to cover the cost of abandonment and remediation of the site. Once abandoned, the status becomes permanent, and re-entering such a well would not be possible.

The normal stages before decommissioning/abandonment of a well are:

- The well is determined to be unusable.
- Perforations are cemented by placing a cement plug below and above them and squeezing cement into the formations to isolate them within the well bore permanently. A mechanical shut-off device called a bridge plug may also be wireline set above the cement plug to add protection or isolation.
- A second cement plug would be set higher in the production casing and below the estimated permafrost maximum depth. This plug is normally set on top of a bridge plug so that it does not leak down in the casing. The plug is also “felt” with a drill bit to confirm its existence and hardness.
- The casing at the surface is cut 1 m below the original ground and buried under the soil to remediate the location entirely. The soil will be left to achieve a frozen state naturally, and permafrost is expected to establish within it at the same depth as the surrounding area.
- The lease is remediated by removing all equipment and infrastructure to restore its original condition. The surface location will be left to revegetate naturally.

When appropriate, a decommissioning/abandonment plan for the well sites will be developed to comply with Part 7 of the *OGDPR* (Sections 95, 96, 97, 99) (Government of Yukon 2004). Wells would require final well abandonment according to the *YOGA OGPDR* (Government of Yukon 2004).

If the entire Project had to be suspended but not completed, the infrastructure would be preserved and maintained until the Project resumes. If it is decided to terminate the Project, the infrastructure will be decommissioned.

1.5.4 Winter Roads and Winter Well Sites

Reclamation activities will promote natural revegetation as quickly as possible throughout the life of the Project. Well site and winter road reclamation activities will be designed to meet the following objectives:

- Leave the site uncontaminated following the completion of Project activities.
- Remove all garbage, petroleum products, and equipment.
- Prevent long-term erosion or slumping and promote successful natural revegetation of disturbed areas.

Given the winter road construction methods that will be employed (i.e., packing snow to a minimum thickness of 10 cm), no additional reclamation is anticipated to be required for the winter roads. Proposed Project activities will take place during winter, and the winter access roads and well site pads will be constructed using snow and ice to minimize damage to the vegetative layer or compaction/scarification of the organic soil layer. The proposed measures to promote successful natural revegetation are:

- Complete removal of equipment, matting, materials and debris from well sites.
- Leaving the well sites and winter roads in such a condition that water ponding, slumping or soil erosion are unlikely outcomes – if (unplanned) soil disturbance takes place, the surface would be contoured to minimize erosion (depending on the area disturbed), roughened, and covered in a layer of mulch or cut vegetation.
- No stockpiles of snow or ice will be left at the well sites or along the winter roads, to minimize melt-related effects on vegetation.
- During winter road construction, trees and shrubs will be cleared but ground vegetation will be left intact and protected via minimum 10 cm packed snow or rig mats. Large trees and shrubs may be hand cut and piled adjacent to the road for later use during road reclamation when they will be used to form brush piles on the road would be expected to inhibit human travel and provide ongoing soil/non-woody vegetation protection post-melt.

Access to winter roads will be restricted during and after the Project. Restricting access will support spring melt, and reduce the potential for additional disturbance from outside users and reducing risk to Chance employees and the public.

1.6 REGULATORY CONTEXT

Permits, approvals, conditions, authorizations and licences that could be required for the Project include the following Decision Bodies, relevant Acts and associated regulations:

- Yukon Government:
  - *Boiler and Pressure Vessel Act, RSY 2002, c 16* (Government of Yukon 2002a);
  - *Dangerous Goods Transportation Act, RSY 2002, c 50* (Government of Yukon 2002b);
  - *Environment Act, RSY 2002, c 76* (Government of Yukon 2002c);
  - *Forest Protection Act, RSY 2002, c 94* (Government of Yukon 2002d);
  - *Forest Resources Act, SY 2008, c 15* (Government of Yukon 2008);
  - *Highways Act, RSY 2002, c 108* (Government of Yukon 2002e);

- *Historic Resources Act, RSY 2002, c 109* (Government of Yukon 2002f);
- *Lands Act, RSY 2002, c 132* (Government of Yukon 2002g);
- *Public Health and Safety Act, RSY 2002, c 176* (Government of Yukon 2002i);
- *Territorial Lands (Yukon) Act, SY 2003, c 17* (Government of Yukon 2003a);
- *Waters Act, SY 2003, c 19* (Government of Yukon 2003b);
- *Wildlife Act, RSY 2002, c 229* (Government of Yukon 2002j); and,
- *YOGA.*

- First Nations Decision Bodies;
- Federal agencies and Acts:
  - Natural Resources Canada;
  - *Canadian Environmental Protection Act, 1999, SC 1999, c 33* (Government of Canada 1999);
  - *Explosives Act, RSC 1985, c E-17* (*Government of Canada 1985);*
  - *Migratory Birds Convention Act, 1994, SC 1994, c 22* (Government of Canada 1994)
  - *Species at Risk Act, SC 2002, c 29* (Government of Canada 2002); and,
  - *Transportation of Dangerous Goods Act, 1992, SC 1992, c 34* (Government of Canada 1992).

A complete list of required permits, approvals, authorizations and licences will be verified as needed as the Project progresses through the approval process with the relevant Decision Bodies, as identified by YESAB. Permits and licences will be obtained from the appropriate regulators (e.g. territorial government, federal government, First Nations governments) specific to the Project activities and location before work starts.

1.6.1 Requirement for an Executive Committee Screening

In July 2014, Northern Cross (Yukon) Limited submitted a Project Proposal (YOR project # 2014-0112) to the Dawson Designated Office (DO) for an exploratory drilling program in the Eagle Plains region, consisting of up to 20 oil and gas wells, and supporting activities such as winter and all-season roads, disposal locations for drill cuttings and camp facilities for project personnel (Northern Cross (Yukon) Ltd. 2014). The proposal's adequacy review was completed on October 30, 2014, and the evaluation was completed in December 2015.

In February 2016, the Dawson DO referred the Project to the Yukon Environmental and Socio-Economic Assessment Board (YESAB) Executive Committee for screening under s. 56(1)(d) of the *Yukon Environmental and Socio-economic Assessment Act, S.C. 2003, c. 7* Government of Yukon. 2003c. (*YESAA*) The Project was referred for an Executive Committee screening as the DO was unable to determine the likelihood of significant adverse effects on the Porcupine Caribou Herd; the DO was unable to determine the probability or magnitude of changes to caribou migration and seasonal distribution in relation to project activities and the associated duration, reversibility, and extent of such effects. The report stated: "… *after taking into account any mitigative measures included in the project proposal, it cannot determine whether the project will have, or is likely to have, significant adverse environmental or socio-economic effects*". A copy of YESAB's Designated Office Evaluation Report is attached in **Appendix 1-A Designated Office Evaluation Report, YESAB, February 9, 2016.**

With ownership changes and a name change to Chance Oil and Gas Ltd., Chance reviewed its business plans and decided to proceed with a more ambitious exploration program over a larger area within the

Exploration Permits previously awarded to the company by the Yukon Government. Rather than undertake the project that YESAB Designated Office in Dawson referred to the Executive Committee in early 2016, the company proposed to launch an expanded exploratory drilling program as proposed in this submission.

Engagement with affected First Nations with their government officials and with the communities at large in respect to the expanded exploration project started in 2017 and continues to the present, but progress was adversely affected by restrictions imposed to address the COVID-19 pandemic from 2020 to 2022. Discussions also commenced with representatives of the Yukon Government in 2017 and have continued since then, subject to restrictions imposed by the COVID-19 outbreak.

Chance and their consultants have undertaken additional baseline data collection and analysis to support predictions of potential Project effects on the Eagle Plains environment, wildlife, and to better understand the potential socio-cultural interactions with the Project. In addition, Chance Oil and Gas Ltd. has developed and implemented a consultation and engagement plan with First Nations and residents of communities to meet the requirements of *YESAA* s.50(3). Environmental baseline data-gathering studies were undertaken in 2019, 2020, 2021, 2022, and 2023 to support the larger exploration project. Two Heritage Resource field studies were also done in the summers of 2022 and 2023.

Due to the Project changes and the implementation of YESAB's Pre-Submission Engagement process for Executive Committee screenings, a comparison of the original Project activities and the Project activities in their current iteration was prepared at the request of the Executive Committee. This comparison was intended to assist the members of the Executive Committee in determining whether the Project in its current form was sufficiently similar to Project YOR# 2014-0012 for them to be considered the same Project, or whether the Project as it is now should be considered a new project.

In July 2022, Chance submitted the comparison table of proposed Project information based on 2022 and 2014 details to the YESAB Executive Committee to verify the appropriate regulatory process (Aasman 2022). Upon review of that memorandum, YESAB (2022) stated, "*The Executive Committee has determined that while your 2022 project contains material changes, these changes are not fundamentally different than your 2014 project*." The 2022 project was defined as a referred project per s.4 of the Screening Rules. Further, Chance was directed to submit a revised proposal for evaluation to the Executive Committee under s.56(4) of the *Yukon Environmental and Socio-economic Assessment Act.* The letter went on to further describe the adequacy review process.

To continue the process and obtain clarity between Chance and YESAB, on August 23, 2023, Chance met with the YESAB Executive Committee, whereby the project and regulatory pathway were discussed and clarified. On September 5, 2023, YESAB followed up with a letter to Chance (YESAB 2023) defining the process for a referred project. The letter stated, "*As this is a referred project, the typical Pre-Submission Engagement process does not occur, and therefore no Project Description is expected, and no Project Proposal Report will be issued prior to Project Proposal submission*."

The letter also stated that a comprehensive revised Project Proposal was to be submitted to the Executive Committee, detailing the Project as proposed, the current conditions, associated data and Traditional Knowledge, and detailed effects assessments. In addition, the submission is to include a complete consultation and engagement record.

Therefore, the Project herein is subject to an Executive Screening by the Executive Screening Committee under the *Act* as a Referred Project.

1.7 CONSIDERATION OF REGIONAL LAND USE PLANS

The North Yukon (NYRLUP) and Peel Watershed (PWRLUP) Regional Land Use Plan boundaries (Vuntut Gwitchin Government and Yukon Government 2009, Peel Watershed Planning Commission 2019) encompass the Project RSA. The Project occurs in the area identified by both plans for higher levels of development, in part because of the expected oil and gas potential. Project mitigations address the RLUPs General Management Directions, and the Project is designed while considering the Recommended Best Management Practices. This section describes the key features of those plans relevant to the Project's environmental assessment.

Yukon RLUPs are developed to address Section 11 of the Umbrella Final Agreement (UFA, Council for Yukon Indians et al. 1993). The RLUPs are intended to help ensure that "…*social, cultural, economic and environmental policies are applied to the management, protection and use of land, water and resources in an integrated and coordinated manner so as to ensure Sustainable Development*" (Section 11.1.1.6 of UFA). Based on those intentions, the plans identify how and where land uses may or may not occur. Land Use Plans are developed and approved by the Yukon Government and affected First Nations as the areas apply to their land base (e.g., Traditional Territories).

The Project's RSA is encompassed within the approved North Yukon RLUP (NYRLUP; Vuntut Gwitchin Government and Yukon Government 2009) and approved Peel Watershed RLUP (PWRLUP; Peel Watershed Planning Commission 2019) (**Map 1-4, Table 1-7**). Most of the RSA is encompassed within the NYRLUP's Land Management Unit (LMU) #9. The southwest corner falls within the PWRLUP's LMU #7 (Dalglish Creek). Both LMUs recognized the high oil and gas development potential and are considered Integrated Management Area Zone IV — Highest Level of Development (Summarized in Table 3.1 in each plan).

The NYRLUP (Vuntut Gwitchin Government and Yukon Government 2009) divides the Planning Region into 23 land management units classified into three categories: protected area, integrated management area (IMA), and community area. IMAs are further classified into four zones: Zone 1 (lowest development), Zone II (low development), Zone III (moderate development), and Zone IV (highest development). IMA zones are classified based on the area's sensitivity to landscape disturbance, ecological and cultural values, risk of significant impacts, and level of acceptable change. The RSA is in a Zone IV IMA, with lower ecological and cultural values in a moderately sensitive biophysical setting. Subsequently, Zone IV IMAs allow for the highest development level to occur. Forty-nine (49) percent of the NYRLUP is categorized as some form of protection (**Table 1-7**).

Relevant to the Project, the NYRLUP acknowledges (pg. 5–29) that

> *"Standard oil and gas industry practices have a much smaller footprint and impact on ecological values than practices used in the 1960's [sic]. Current operating practices significantly reduce the potential for major long-term impacts. Given the current low levels of activity, existing site-specific best management practices, used in combination with the direction provided by this Plan, are considered adequate to mitigate potential impacts of oil and gas activity."*

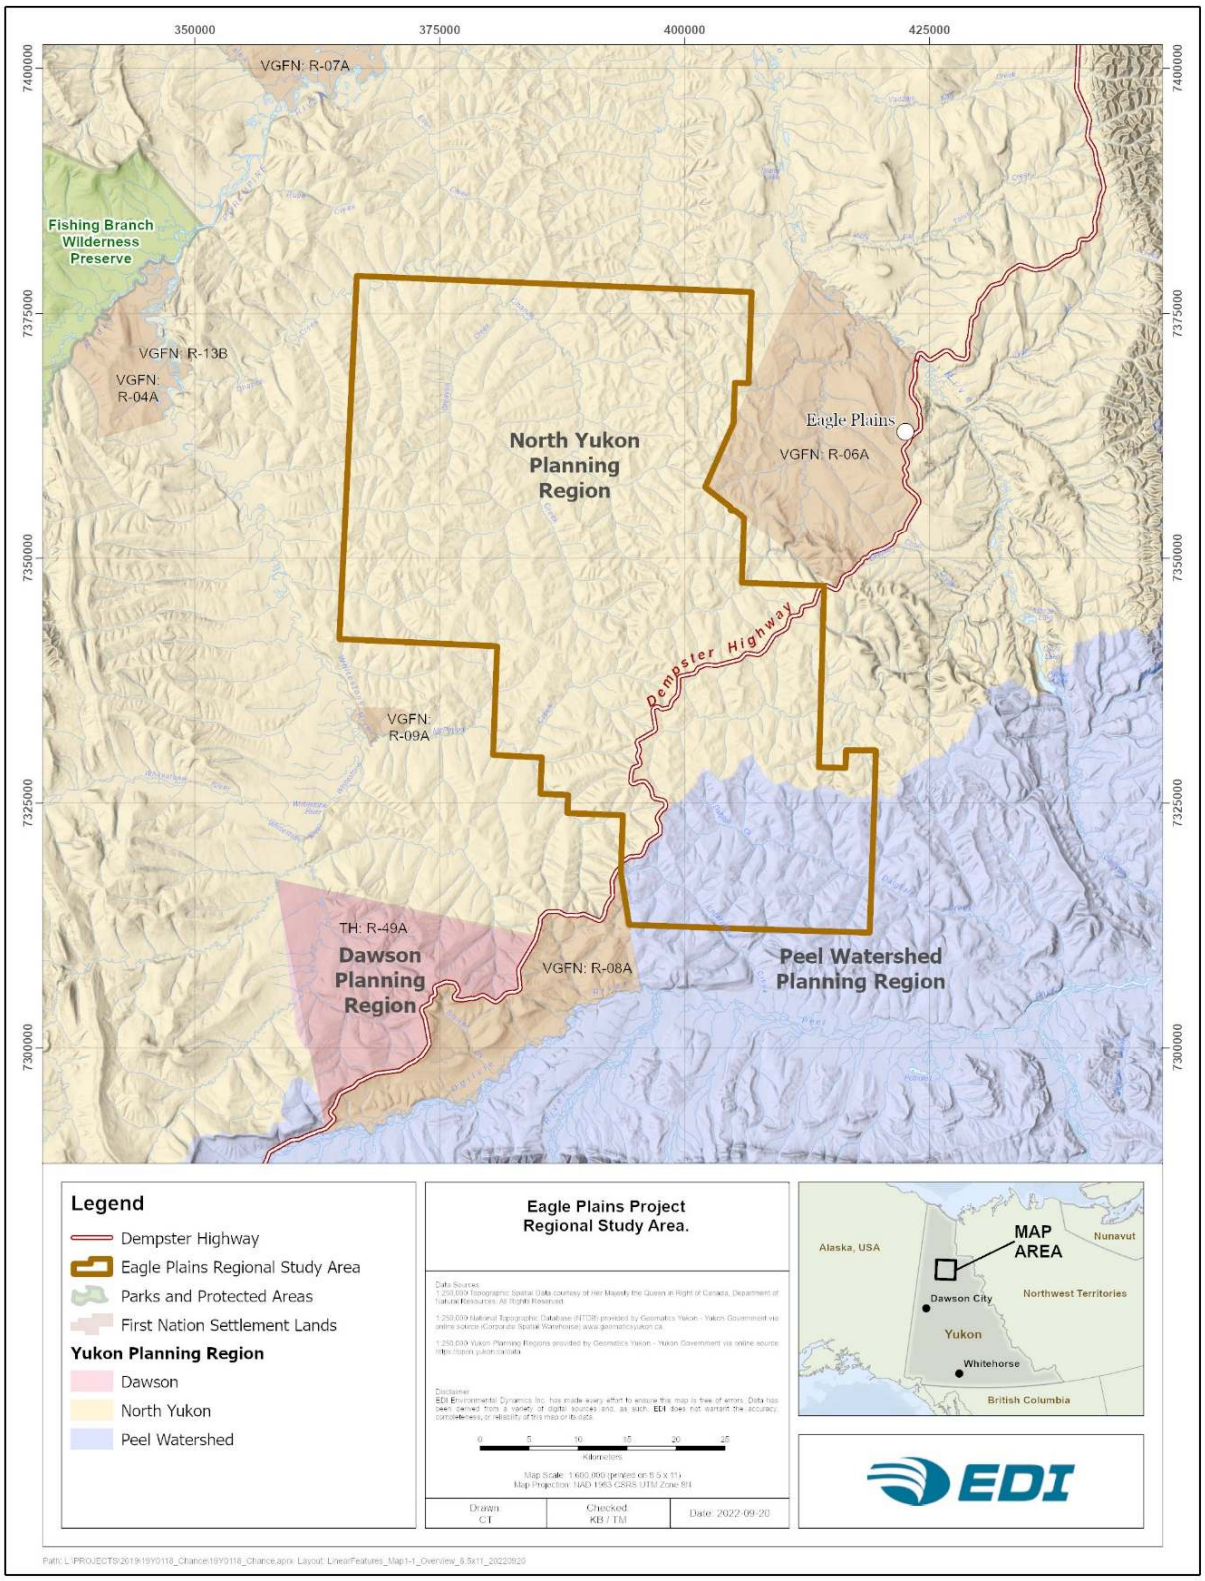
The southeastern corner of the RSA lies within the PWPRLUP (Peel Watershed Planning Commission 2019). Following a framework like the NYRLUP, the PWPR is divided into 16 LMUs, each with similar

ecological characteristics, planning issues, and management intent. Each LMU is categorized by a land-use designation system. Like the area designation in the NYRLUP, the RSA portion in the PWRLUP is in IMA Zone IV, LMU 7 (Dalglish Creek), allowing for the highest level of development. Eighty-three (83) percent of the PWPRLUP is categorized as some form of protection (**Table 1-7**).

Protected/Conservation areas[1] account for 61% of the combined planning areas (49% in the NYRLUP, 83% in the PWRLUP). The Project does not occur in any of those protected areas. The LMUs encompassing the RSA are 8,014 km² (6% of the combined NYRLUP and PWRLUP). The 2,386 km² RSA represents 2% of the combined area of the NYRLUP and PWRLUP (**Table 1-7**).

The NYRLUP identified some industry-specific disturbance issues, while the PRWLUP identified concerns as LMU Objectives. Those issues and how they cross-reference to how and where they are addressed in this Project Proposal are summarized in **Table 1-8**.

[1] Protected areas: removes an area from oil and gas and mineral disposition, and prohibits exploration activities (Peel Watershed Planning Commission 2019)



Map 1-4: Eagle Plains Project Regional Study Area

Table 1-7: Key Facts of the Regional Land Use Plans Relevant to the Eagle Plains Exploration Project

Spatial Features	NYRLUP		PWRLUP		Combined	
	LUP Area (km^2)	% of LUP Area	LUP Area (km^2)	% of LUP Area	LUP Area (km^2)	% of LUPs Area
The total area encompassed by the Planning Region	55,548	na	67,431	na	122,979	na
Conservation/Protected Area, Habitat Protection Area, and Land Withdrawal	27,145	49	55,858	83	75,497	61
LMU #9 (NYRLUP) and LMU #7 (PWRLUP)	6,415	11	1,599	2	8,014	6

Table 1-8: Environmental Issues Identified in the Land Use Plans with a Cross-Reference to How They Are Addressed in the Project Proposal

Identified Environmental Issue	How addressed in this Project Proposal	Relevant Section(s)
NYLUP (Vuntut Gwitchin Government and Yukon Government 2009, pg. 5–29)		
Oil and gas exploration and development activities and associated land uses (transportation, gravel extraction, and water withdrawal) can cause cumulative and adverse changes over large landscapes.	Acknowledged, and these issues are focus areas in the Project Proposal.	• Water withdrawal is addressed in **Section 5.** • Gravel extraction is not a part of the Project. • The Project Proposal addresses cumulative effects following methods outlined in **Section 3**.
Impacts could affect valued ecological resources, including Porcupine Caribou Herd (PCH), moose, marten, wetlands, lakes and rivers.	The potential Project-related effects on the PCH, moose, and marten are addressed explicitly in this Project Proposal. Wetlands, lakes and rivers are addressed as ecological landscape units of importance.	• PCH: Section 9 • Moose: Section 8 • Marten: Section 8 • Wetlands, Lakes and Rivers: **Section 7**
The construction and ongoing operations of large-scale oil and gas infrastructure would bring many new workers to the region.	The Project Proposal is for an oil and gas exploration project. It does not result in ongoing operations. There is no substantial infrastructure. Workers are temporarily housed in a remote camp. Largest work force no larger than 80 people	NA
Coordinated and effective management of the PCH habitat and population requires an integrated management approach in advance of increasing industrial land use.	Porcupine Caribou Herd management is integrated among the management authorities (territorial, state, federal, First Nation) and the Porcupine Caribou Management Board.	The Porcupine Caribou Herd management overview is provided in **Section 9**.
Land use conflicts might arise between: a) oil and gas and wilderness/cultural tourism;	Land use conflicts are possible, although no known or future tourism operators exist in the exploration area.	• Potential for land use conflicts are addressed in the **Section 11.** • The exploration project's potential effects on PCH use of

Identified Environmental Issue	How addressed in this Project Proposal	Relevant Section(s)
b) oil and gas and traditional economic activities and cultural pursuits; and, c) oil and gas and PCH use of winter range.		winter range are addressed in **Section 9**.
PWRLUP LMU #7 Objectives (Peel Watershed Planning Commission 2019, pg. 95)		
1. Ecological integrity is maintained.	The broad term "ecological integrity" is addressed by considering associated Valued Environmental and Socio-economic Components (VESECs) included within the water, fish, vegetation, and wildlife-focused assessments.	• Water: Section 8 • Fish: Section 6 • Vegetation: **Section 7** • Wildlife: **Section 8**
2. Some culturally and ecologically-aware resource exploration and extraction that supports the local economies.	This Project Proposal is intended to reflect that Chance's awareness of the area's ecology, values of interest, and protection plans that will be in place to support an exploration project in IMA IV-designated lands for the highest development level.	Project Proposal submission, effects assessment, and proposed protection plans.
3. All permitted land use activity does not significantly impact movement and habitats of caribou.	The Project's potential effect on caribou movement and habitat are addressed using all available information and best environmental assessment practices.	PCH: **Section 9**
4. Industrial activity does not result in any alteration to the Peel River's viewscape.	The Project is not visible to Peel River users and does not alter the Peel River's viewscape.	NA

1.7.1 Cumulative Effects Indicator Levels

The RLUPs encourage results-based management and use cumulative effects indicators to determine if goals and objectives are met. Direct surface disturbance and linear density are the two cumulative effects indicators included in the Plans. The Zone IV IMA guidelines (i.e., cumulative effects indicator levels) are 0.75–1.0% surface disturbance (of IMA – Zone IV) and 0.75–1.0 km/km² linear density (Table 3.2 in both RLUPs).

Activities considered exempt from functional disturbance restrictions are (1) new linear features less than 1.5 m wide; (2) land-use activities that occur on frozen water bodies; (3) winter work with no required clearing of trees; and (4) winter work that uses existing disturbances and linear features.

Although both plans suggest the indicator values noted above,

> *"The recommended indicator levels serve as a benchmark, and provide the Parties responsible for plan implementation an opportunity to review and consider the potential outcomes of resource management decisions. They will also assist in the YESAB process by providing an indication of potential cumulative effects within a LMU"* (NYRLUP, pg.3–6).

As surface disturbances and linear features reach a level of functional recovery and become part of the continuous landscape, they can be subtracted from the total amount of disturbed area (Vuntut Gwitchin Government and Yukon Government 2009). The RLUPs suggest using a height of 1.5 m for woody vegetation in forested areas, as vegetation above that height would likely inhibit travel or access by humans or wildlife and is, therefore, considered functionally recovered. In areas dominated by low-growing vegetation, a feature could be considered functionally recovered when covered by native species roughly the same height and composition as the surrounding vegetation. To be considered "functionally recovered", features must have similar sediment and run-off compared to background levels, roughly match original contours, and have no human-brought materials on the site.

1.7.1.1 Linear Features Study: Characteristics and Quantification

Intermittent exploration activities in the Eagle Plains area from the 1950s to 2014 have created a network of winter roads, 2D seismic lines and, most recently, 3D seismic lines within the RSA. Recognizing previous and planned activities and the concerns around the indicators presented in the RLUPs, Chance commissioned a study to determine the extent and characteristics of linear features in the Project footprint (**Appendix 1-B Linear Feature Study**). The study addressed three objectives: (1) comprehensive mapping and classification of existing linear feature footprints within the RSA; (2) quantification of structural aspects (e.g., widths) and functional aspects (ease of travel and sightlines) of linear features; and (3) quantification of regeneration pathways and structural stages of linear features. Key findings from that study relevant to this assessment and consideration as cumulative effects indicators include:

- Structural, vegetation, and functional characteristics differed substantially among linear feature types. 3D seismic accounts for the largest extent of linear features in the RSA and had the narrowest widths and limited functional effects (e.g., the proportion of features used by ungulates in the winter was less than a third of the rates of use on 2D and winter roads). Winter roads, except for the Dempster Highway, had the widest average widths and the greatest functional effects. However, a substantial portion (39%) had regenerated into or past the Tall Shrub stage (which this study suggests may be the best criterion for functional recovery). Most 2D lines had substantial vegetation regeneration, resulting in the shortest average sightlines and the slowest movement speeds. However, ungulates still appeared to select them to travel during winter.
- Four primary types of linear features occur in the RSA, totalling 4,269 km: 2D seismic (34%), 3D seismic (51%), winter roads (14%), and the Dempster Highway (1%). The unadjusted linear feature density for the RSA totalled 1.79 km/km². After accounting for burns, natural openings and regeneration, the adjusted linear feature density for the RSA totalled 0.52 km/km², below the cautionary (0.75 km/km²) and critical (1.0 km/km²) cumulative effects indicator levels in the NYRLUP and PWRLUP.
- Substantial vegetation regeneration has occurred on existing features in the RSA. Previous work by the Yukon Government identified the potential for atypical successional trajectories to occur on linear features in the region. Although atypical succession occurred to a limited extent, the study of the linear feature determined that 81% of the sites exhibited a normal succession (100% on 3D lines). Only 5% exhibited inhibited regeneration trajectories (mostly stagnated succession on winter roads). Regarding functional recovery, 53% of sites met the NYRLUP and PWRLUP criterion of vegetation reaching 1.5 m, and 38% met the criterion of attaining a

Tall Shrub structural stage. Using the Tall Shrub structural stage as a criterion of functional recovery may be a more ecologically appropriate criterion to meet LUP objectives.

- The extent of open habitats (e.g., burns, wetlands and shrublands) and the degree of regeneration on existing linear features (mostly the older 2D lines and winter roads) play an important role in calculating effective linear feature density in the RSA. Before accounting for open areas and regeneration, the total linear feature density was 1.79 km/km². After accounting for open areas and vegetation regeneration (to the Tall Shrub structural stage), the effective linear feature density was 0.52 km/km².

The results and their relationships to the cumulative effects indicators are discussed where relevant in the following sections of the Project Proposal.

1.7.2 Conformity with Land Use Plans

Chance has had preliminary written discussions with the Yukon Land Use Planning Council regarding the information requirements for a conformity check with the NYRLUP and the PWRLUP. A conformity check across the two plans will include several elements. New spatial disturbance and linear density calculations will be added to existing disturbances. Other components include a review of the baseline data. For the PWRLUP, the parties have attempted to clarify their expectations with the 2022 Standard Terms and Conditions (Peel Plan Implementation Committee 2022). Additionally, the conformity review will address the objectives for LMU # 9 and #7 of the relevant plans and any relevant "Special Management Considerations" set for each LMU. That information compilation and conformity discussions will be concurrent with this YESAB proposal review.

1.8 EFFECTS OF THE ENVIRONMENT ON THE PROJECT

Climate change, from the human-caused increase in greenhouse gases such as carbon dioxide, is reportedly increasing the frequency and intensity of extreme weather events including heavy precipitation, severe floods, prolonged droughts, and increased wildfires around the globe (National Aeronautics and Space Administration [NASA] 2023, Environment and Climate Change Canada [ECCC] 2019). Climate is changing in the Eagle Plains area, as it is throughout Yukon, more rapidly than at southern latitudes (BNQ 2023).

Given the remote, northern location of the Project, potential effects of the environment on the Project could result from climate change effects such as permafrost changes and terrain instability, extreme weather, increased wildfire frequency, and fluctuating water levels in lakes and rivers. Details related to mitigating associated risks to the Project are further discussed below.

1.8.1 Climate Change and Terrain Instability

The Project Area is underlain by continuous permafrost (Heginbottom et al. 1995), ground that remains below 0°C for more than two years. Permafrost is approximately 100 to 200 m thick, based on measurements and calculations from drill holes (See **Appendix 4-A** of **Section 4 Permafrost and Terrain**). The active layer, overlying permafrost and subject to seasonal freeze-thaw cycles, varies in thickness based on elevation, aspect, slope position, sediment texture, snowpack, and vegetation cover. It is commonly as

thin as 0.5 m and up to several metres thick in areas recently burned by wildfire. Active layer detachments are translational landslides that occur from thawing soil above permafrost in the summer. Although increasing since 1992, they are not prevalent but occur on some steeper slopes (Haseldine 2021). Thermokarst is very localized in some sections of valley bottom, and retrogressive thaw flows are rare.

Due to climate change, continued warming of air temperature and changes in precipitation patterns are already affecting near-surface permafrost and associated terrain stability. Gradual (mm/year) degradation (thawing) of permafrost is likely to increase thermokarst subsidence and the size and distribution of active layer detachments, which, in turn, may affect local hydrology, sediment delivery to watercourses, and rates of erosion. Additionally, more frequent and severe wildfires may exacerbate permafrost thaw by removing insulating vegetation and increasing summertime warming. Terrain stability is gradually decreasing, in certain areas, in association with climate change. Degrading permafrost, largely through its influence on terrain stability, has the potential to locally affect certain components of the Project.

Poorly routed or sited Project infrastructure could be subject to differential subsidence, driven by thermokarst subsidence, with potential effects on the integrity of the infrastructure and a heightened need for maintenance. It could also be unnecessarily exposed to mass movements such as rockfall, active layer detachments, retrogressive thaw flows or solifluction, all of which could damage surface infrastructure.

Exploration development suitability maps (See **Appendix 4-A** of **Section 4 Permafrost and Terrain**) highlight variability in observed and potential landscape response to climate change (and anthropogenic surface disturbance), and where the environment has the greatest potential to affect the Project, without mitigation. As discussed in Section 3 Methods, environmental constraints mapping, which outlines sensitive or high quality environmental and heritage values where Project work is to be avoided or minimized, was undertaken. The mapping of permafrost and terrain sensitive areas was included in constraints mapping for potential avoidance or minimization of Project work, where possible. Particular attention will be given to locating infrastructure, such as camps, staging areas and well pad sites, within appropriate areas of suitability. Winter roads are best established outside such areas, as well, although measures are readily available to mitigate risks where crossings of such areas are unavoidable (**see Section 4.3**). Further mitigation measures appropriate to address the potential effects on the Project due to permafrost related terrain instability are discussed in **Section 4 Permafrost and Terrain**.

1.8.2 Extreme Weather

The potential for extreme weather conditions will be discussed in the Chance comprehensive HS/ERP including appropriate mitigation measures related to extreme weather conditions that may affect field personnel and the undertaking of all Project components. For example, extreme weather events may include variable weather conditions including severely cold temperatures, intense winter storms (blizzard/white out conditions, heavy snow, freezing rain, high winds), which may cause delays in site mobilization and transportation of goods and services, increase personnel health and safety risks, and cause delays. Mitigation measures appropriate to address the potential effects on Project personnel and equipment due to extreme weather may include, but not limited to:

- Reduce the risk of hypothermia and frost bite by dressing in layers, carrying spare clothing, covering exposed skin, and utilizing available heated shelters.
- Provide adequate navigation and communication systems.

- Evaluate transportation conditions (road reports and closures, flight conditions, use of Journey Management processes).
- Provide First Aid training for personnel.
- Provide Common Safety Orientation (including extreme weather) for personnel.
- Design for and adjust exploration as appropriate for site conditions (e.g., cold-weather rated equipment, use of heaters for equipment, overhead hazard awareness during high winds, equipment tie downs, other activity considerations).

1.8.3 Wildfires

The potential for wildfires will be discussed in the Chance comprehensive HS/ERP and will include appropriate mitigation measures related to potential effects of increased wildfire frequency in the Project area which may affect field personnel and the undertaking of all Project components. For example, wildfires in the region could cause Project delays, increase personnel health and safety risks, and affect site mobilization and transportation of goods and services due to air quality concerns and road closures. In addition, as stated above, more frequent and severe wildfires may exacerbate permafrost thaw by removing insulating vegetation and increasing summertime warming. The interactions between wildfires and permafrost are detailed in various regional studies (French et al. 2016, Kokelj et al. 2017, Perrin and Jokowski 2022). Wildfire mitigation measures may include, but not limited to:

- Evaluate forest fire conditions/reports in the area.
- Work closely with representatives on Yukon Fire Management if fires in area
- Evaluate air quality conditions and forecasts from wildfire smoke in relation to relevant air quality health indices.
- Follow appropriate procedures for storage of flammable goods.
- Provide forest fire response procedures (personnel notification, evacuation).
- Provide forest fire reporting procedures.

1.8.4 Fluctuating Surface Water Levels

Water levels in Yukon lakes and rivers are affected by several processes that are influenced by climate change, including amount and timing of snowmelt, precipitation, permafrost thaw, groundwater flux and melting glaciers. Such processes may affect water levels in the proposed water extraction sources identified for the Project. Measures to mitigate the potential low water levels from Project-identified water sources are described in **Section 5 Water Resources** and will be a component to a Chance Environmental Management Plan (EMP). In winter exploration, it is more likely that the Project will be affected by low flow versus high flow water events due to water source and quantity requirements for various processes. Mitigation measures may include, but not limited to:

- All works with the highest water requirements will be planned to occur in November, December, and, to a lesser degree, January, increasing the confidence that adequate water is available for the proposed work and to manage access to available flow during the lowest flow periods (February and March).
- Collect weekly or bi-weekly flow measurements at the point(s) of withdrawal to determine 10% of the actual flow instantaneous discharge and monitor discharge.

- Develop and implement plans to reduce water withdrawals, should the instantaneous monitoring data indicate unacceptable direct hydrologic effects (e.g., flows below 10% instantaneous flows) or indirect effects (e.g. increased channel erosion.
- Bottled drinking water will be supplied to the camp.
- Construction of a heated water reservoir at the camp for water storage and use during low water periods will be completed.

Please refer to the list of management and monitoring plans anticipated for the Project included in **Section 12.** Each management and monitoring plan will be prepared for the Project's specific needs and will include a complete list of associated mitigation measures, when developed.

1.9 AIR AND GREENHOUSE GAS (GHG) EMISSIONS

According to Natural Resources Canada (2014), greenhouse gases (GHGs) include carbon dioxide, nitrous oxide and methane, where carbon dioxide is the principle GHG. Carbon dioxide is a colourless, odourless, non-flammable gas produced by the combustion of fossil fuels including gasoline and diesel. Carbon dioxide emissions contribute to climate change.

1.9.1 Direct Air Emissions

1.9.1.1 Flaring

Flaring is the principal source of air emissions related to EFT of natural gas discoveries and will be conducted in compliance with regulatory controls over a short time period, likely a week to one month in duration, as EFT activity at a predominantly natural gas bearing zone may be completed within several weeks in comparison to a predominantly crude oil-bearing zone where EFT activity may require up to 2 winters (but with minimal flaring of natural gas required). Natural gas is dissolved in crude oil in most instances so there will likely be some flaring at EFTs of oil discoveries. Natural gas may be flared but preferentially used as fuel for process heating, mechanical power, and onsite power generation for the Project. It is not anticipated that any oil produced during EFT will be burned during flaring, as it will be captured and trucked offsite.

Flaring consists of burning off natural gas at height. The resultant combustion products are water vapour, carbon dioxide and possibly small quantities of sulphur dioxide (if hydrogen sulphide is present in the natural gas). Hydrogen sulphide is not expected based on data obtained historically and during drilling activities conducted by Chance between June 2012 and June 2013. It is expected that exhaust gases will dissipate upwards into the atmosphere.

Flaring of residual solution gas that is not consumed for use of process heating or engine power (mechanical or electrical) will occur. Use of natural gas extracted from crude oil during EFT will displace use of propane or diesel for consumption and may result in emissions reduction by an estimated 50% compared to propane and diesel use.

Depending on surface conditions, the flare stack will be a minimum of 18 m high and a maximum of 30 m high to assist in air dispersal of combustion end products and mitigate effects on vegetation, trees and permafrost. Flaring of gases during the EFT will occur under regulatory controls. Gas will be control-burned through the flare stack following the flare permit issued by the Government of Yukon, Oil and Gas Branch.

The Yukon government regulates air quality under the *Environment Act,* RSY 2002, c.76 (Government of Canada 2002) and the *Air Emission Regulations*, YOIC 1998/207 (Government of Canada 1998), and by issuing Air Emissions Permits for specific activities which are required before proceeding. When an activity requires an Air Emissions Permit, it must comply with the published regulated air quality criteria in Yukon Ambient Air Quality Standards (AAQS) (Yukon Environment 2019 a). Flaring related to EFT requires an Air Emissions Permit from Yukon Environment. Data requirements for flaring are provided in the *Guidelines: Flaring, Venting Reduction, and Fugitive Emissions* (Yukon Environment 2019b). Following these guidelines, Chance will determine the sulphur dioxide content of the natural gas from each well where EFT is being conducted before flaring; if the content of sulphur dioxide exceeds 5 mol, air dispersion modelling will be prepared for submission to *OGDPR* (Government of Yukon 2004) for review and approval. The collection of sulphur dioxide data on specific wells must be determined in the field.

The proposed Project is an exploration project; therefore, outcomes of potential oil and gas discoveries and volumes are difficult to predict and depend on variables such as the actual presence, type and quality of hydrocarbon encountered (crude oil, natural gas) and production rates of the wells.

1.9.1.2 Other Combustion Sources

In addition to flaring, air quality effects may occur from Project activities that require the combustion of fossil fuels during seismic exploration, drilling, EFT, reclamation and closure activities, and are expected to be localized to areas in which equipment is being operated. These combustion sources may include:

- trucks and service vehicles (e.g., pickup trucks, water trucks, fuel trucks);
- ATVs and snowmobiles;
- heavy equipment (e.g. loaders, graders, snow cats, flatbeds);
- air transportation (airplane, helicopter);
- drilling rig;
- mulchers;
- LIS tracked air hammer drilling rig;
- camps (e.g., heating for Chance Camp, remote fly-in camp, wellsite); and,
- equipment (e.g., boilers, heaters, portable generators, mulchers).

The operation of an incinerator for domestic waste will occur and will be done following the *Air Emission Regulations* (Government of Yukon 1998) and permitting conditions, as required.

Fuel types for combustion for the above sources include diesel, propane, gasoline, and aviation fuel (Jet-A). Byproducts from the combustion of these fuel types may include carbon monoxide, carbon dioxide, nitrogen oxides, and particulate matter.

The Project is an exploration project and the number, location and sequence in which wells are drilled for the exploration program depends on seismic data, previous drilling success, EFT results and other conditions; therefore, quantification of air emissions from the combustion of the above fuel sources is not available at this time but will be reported following the relevant territorial and federal air emission regulations.

1.9.2 Fugitive Air Emissions

Fugitive emissions associated with the Project may include releases of fuels or production fluids related to accidents and malfunctions, equipment leaks (e.g., wellhead, well casing, valves, piping), and evaporation losses, including venting from fuel storage tanks and losses from fuel transfer activities.

Methane is the predominant type of greenhouse gas emitted as a fugitive emission in the oil and gas sector; however, carbon dioxide, and nitrous oxide emissions (to a lesser extent) may also occur (Picard 2000)

As outlined in **Section 1.4.9.4**, a fuel storage facility with double-walled fuel tanks for storage of diesel, gasoline, propane and Jet-A fuel will be required for fuel consumption. Operation of the Chance Camp will require diesel and propane consumption. Diesel will be stored on site in 15,000 to 50,000 L Enviro Tanks. It is anticipated there may be up to six tanks at the Chance Camp and up to two at the drilling rig site. The drilling rig, boilers, and light towers at the rig site will have built-in fuel storage tanks. Propane will be stored in propane bullet tanks (approximately 5700 L each): six at the camp and up to two at the rig camp. Fuel for seismic activities will be transported from the main camp area to staging sites in a tank trailer. The seismic equipment is expected to use a combination of gasoline and diesel depending on the machine. Fuel storage will also be required at the remote camp, mobile camps at each active well, and secondary camps required in remote parts of the Project area to support the safety and staging of activities.

Crude oil extracted during DST and, where applicable, subsequent EFT will be stored in up to five surface tanks at the CPF. Storage tanks for the Project will be in compliance with Yukon and Canadian standards and regulations.

Fugitive air emissions related to oil and gas activities are regulated by the YOGA and its regulations including the *OGDPR* (Government of Yukon 2004). Fugitive emissions management will follow the Guidelines: Flaring, Venting Reduction, and Fugitive Emissions (Government of Yukon 2019b) and other relevant legislation and will be included in the EMP.

Developing and implementing a program to detect and repair leaks will be undertaken. These programs will meet or exceed the CAPP BMPs for fugitive emissions management, as required in the Flaring, Venting Reduction, and Fugitive Emissions guidelines (Government of Yukon 2019b).

The Project is an exploration project and the number, location and sequence in which wells are drilled for the exploration program depends on seismic data, previous drilling success, EFT results and other conditions; therefore, quantification of air emissions from fugitive sources is not provided at this time but will be reported following the relevant territorial and federal air emission regulations.

1.9.2.1 Fugitive Dust

Airborne particulates in the form of fugitive dust are anticipated to result primarily from the use of vehicles and equipment on roads or seismic lines in the summer under dry conditions, helicopter take-offs and landings, clearing/mulching of woody vegetation for seismic line preparations, excavation of the MBC sump area, wind erosion on exposed soil, and seismic detonation activities. With the exceptions of seismic operations, Project activities occur mainly during the winter months when soils are frozen and site access can be accomplished via winter roads; therefore, fugitive dust produced by the Project is anticipated to be minimal.

1.10 ACCIDENTS AND MALFUNCTIONS

Accidents and malfunctions could potentially occur during any Project activity. Examples of potential incidents that could be anticipated are discussed in the following subsections. The Chance HS/ERP will further outline the potential accidents and malfunctions that are foreseeable and provide comprehensive management and mitigative measures.

1.10.1 Vehicular Accidents

Due to the remote location and limited availability of skilled personnel and equipment for the Project, people and equipment will likely be mobilized from Northeastern BC and Alberta. Some personnel and equipment may travel from as far as Calgary, Alberta (approximately 3,100 km). Risk of vehicular accidents during ground transportation of personnel and goods increases during adverse conditions (e.g., inclement weather). Chance will identify and mitigate the potential for vehicular accidents as part of the HS/ERP development. The following are examples of mitigative measures to limit the risk of vehicular accidents:

- Transportation of equipment to and from site will follow federal, territorial, and provincial regulations about service hours, dangerous goods transport, and equipment maintenance.
- Chance intends to use local personnel and equipment as much as possible for the Project.
- Posted speed limits must be adhered to and drivers must adjust to weather and road conditions as needed.
- Journey management practices will be used.

1.10.2 Helicopter Operations

During the recording phase of the seismic program helicopters will transport equipment and personnel to areas within the program. The use of helicopters greatly reduces the affects and potential risk to personnel and the environment; however, it does have the potential for crashes, noise, and contact with the propellers and downwash. The appropriate mitigative measures about using helicopters as transportation are:

- Daily flight schedule is to be reviewed along with weather conditions, helipad locations, and locations of all Program crews on the ground.
- Pre-flight checklists are to be complete.
- Pilot “fit for duty” forms and assessments are to be conducted daily.
- All helicopters are to be serviced daily, and a maintenance log and inspection form must be supplied prior to every flight.
- Post-flight inspections and operations debrief make sure that any unforeseen conditions that arise are communicated.
- In the case of a crash the Emergency Response Plan will be enacted.
- All personnel working around helicopters must be equipped with approved hearing protection so that no hearing loss is sustained.
- Wildlife monitors will be employed to scout for wildlife and contribute to operations plans to employ mitigation where wildlife is present.
- The pilot will give personnel general training on helicopter operations for the program as well as pre-flight briefings.

- Any incident involving propeller contact or downwash will be reported and investigated.
- Any disturbance or damage will be remediated to restore it to pre-disturbance condition.

1.10.3 Mulching Operations

During the line preparation activities small, tracked mulching units are used to open areas where timber impedes the ability to drill source holes or layout seismic receivers (geophones). The potential risks are potential contact with mulching debris and the potential to impact the active layer while mulching. The following are examples of mitigative measures of mulching operations:

- Personnel will be provided training regarding the operations and dangers associated with mulching.
- Daily route planning will improve awareness of where the mulchers will be present and determine successive activities outside of the area to be cleared.
- Wildlife surveys will provide feedback that will guide the field operations into an area of low wildlife activity.
- Mulching heads can be raised and lowered to control the distance to the ground. The mulcher head remains 10 cm above the active layer as it is unnecessary to mulch to the ground. Snow depths add buffer as the snow pack protects the ground.

1.10.4 Seismic Hole Drilling

Seismic holes must be drilled to varying depths for the seismic explosives to be loaded into and drill cuttings packed back in. The drill is a small (2.5 m) track mounted rig that will air drill up to 6 m. The hole is 10.2 cm (4”) in diameter. The drilling activity produces a mound of soil that will be packed back into the hole once the charge is loaded (see **Section 1.10.5 Handling, Loading and Detonating Seismic Explosives** for loading operations). The risks associated with drilling are the exposure to rough terrain and the potential for rollover and spills. Appropriate mitigative measures for the handling of explosives are:

- All personnel involved in seismic drilling are properly trained in safe operating and emergency shut down procedures. Drills are only to be operated with a minimum crew of 2 personnel so that a second person is available to assist in case of an emergency. All unnecessary personnel will be removed from the drilling area to limit exposure to the drill and the explosives.
- Routes are carefully selected so that extremely challenging terrain is avoided and lines are moved to less difficult and environmentally sensitive areas.
- Drilling units are top heavy and can pose a risk of tipping. This can lead to accidental spills from the drill unit and potential injury. Terrain must be assessed before drill commencement. As the source lines will have already been cut and surveyed the potential hazards for the drills will be well known and addressed at the pre-operative meeting. Spill kits will be made available and training on their use will be provided. Any spills will be quickly cleaned up, reported as needed, and inspected for appropriate reclamation.
- Drilling will cease in the event of a lightning or thunderstorm in the vicinity.

1.10.5 Handling, Loading, and Detonating Seismic Explosives

Seismic explosives are comprised of 1 kg dynamite charges and a detonator cap. These are transported in an approved truck designed for transporting the dynamite and detonator caps in separate compartments. The magazine will be stored at an approved and permitted staging site. Charges and caps are then moved to the drill hole locations in portable magazines mounted on the drilling rig. The risks associated with charges are the exposure to the explosives and detonator caps, potential for accidental detonation, potential for theft, potential for fire and the potential for a missed detonation. The risks associated with drilling are the exposure to rough terrain and the potential for rollover and spills. The following are examples of mitigative measures about shot-hole drilling:

- All personnel handling explosives and caps must have the appropriate PPE and the proper training and clearance for Ground Disturbance, Transportation of Dangerous Goods and Blasting as Yukon Territory requires.
- All sections of the Canada *Explosives Act*, RSC 1985, c E-17 (Government of Canada 1985) and Regulations shall be followed in purchasing, transporting, storing, and handling seismic explosives.
- Contractors must be covered under the Canadian Association of Geophysical Contractors Explosive Emergency Response Plan (EERP) or other approved plan by Natural Resources Canada (NRC).
- Unnecessary personnel will be removed from the areas where explosives are present.
- Explosives and detonators are to be transported provided that separate, enclosed and locked Type 6 magazines are used and separated by no less than 15 cm of solid lumber between the magazines.
- Magazines are to be kept locked except when opened for depositing or removing the contents. Contents are removed from the drill magazine and stored in the main magazine at the explosive staging site.
- A digital drill logging system will be used to record the date, time, depth and amount of explosives and detonators used at each drilling location (known as a source point). These digital drill logs are cross referenced to the coordinates of the source point as well as whether the detonation was successful. This produces a complete digital profile of all of the explosives used for the seismic acquisition.
- All materials are to be stored at staging sites approved by the Yukon Workers Compensation Health and Safety Board in NRC-approved explosives magazines that are locked, access-controlled and physically monitored daily. Magazine sites are carefully chosen for maximum security and fire control.
- Vegetation is cleared from the magazine site for a distance of 25 m.
- No smoking is permitted within the explosives magazine site.
- No use of cell phones or radios permitted in the vicinity.
- No storage of combustible materials or fuel on magazine site.
- Magazine will be frequently cleaned to remove grit, sand or abrasive materials, as these can compromise explosives.
- Vehicles must not be parked within the 25 m vegetation clearance zone.
- Fire extinguishers will be present.

- Fire procedures will be discussed with all employees and drills will be conducted so that the safe mitigation of the explosives and evacuation of personnel.
- Personnel are monitored as to their location in the field and proximity to explosives with the use of online tracking software and the use of geofencing around magazine sites.
- Small fires outside of the 8 m safety zone can be mitigated by making sure that the magazine is closed and locked and extinguished using the appropriate fire extinguishers.
- In the case of a lightning strike in the area of the magazine the door will be closed and locked and personnel evacuated from the area.
- In the case of a forest fire all authorities will be notified immediately of the magazine site so that they are aware of the danger in that location.
- All source holes are logged and during the seismic acquisition activities a team of seismic "shooters" are deployed to individually prime and set the charge off. Each hole is recorded as being successfully detonated or no detonation. In the result of a no detonation hole the leads are removed and the dynamite is left to disintegrate and become inert. No detonation holes are rare as all detonators are tested for working condition prior to loading the hole. Any unexploded charges are reported to the government with all of the information pertaining to the loaded hole including location and charge size.

1.10.6 Releases to the Environment

Although deemed unlikely, Chance will be prepared to deal with unanticipated releases to the environment including releases to the atmosphere, water and land surface, and these proven, appropriate mitigation measures will be included as part of the development of the Chance HS/ERP and EMP

Examples of atmospheric releases that may occur include methane and hydrogen sulphide (H_2S) releases (dependent on H_2S concentration in the reservoir). Appropriate mitigation measures pertaining to atmospheric releases may include:

- Onsite personnel will receive appropriate operational and safety training for each task undertaken and will use appropriate personal protective equipment (PPE).
- Onsite personnel will be trained in emergency procedures in the event of an atmospheric release.
- Best management practices and safe operating procedures will be adhered to, to minimize risk of releases.
- Well testing equipment with pressurized vessels and flare stacks will be used on site to mitigate atmospheric releases.
- Well heads and blowout preventers are designed with backup systems to support rapid containment in the unlikely event of a release.
- Neutralizing chemicals such as H_2S Scavenger will reduce the potential for H_2S release, where appropriate. However, the presence of H_2S at well locations for the Project is not expected based on historical data.
- Safety systems will prevent or minimize release at the source (e.g., automatic shut-offs, containment systems).
- Use of detection and monitoring systems to allow for early intervention and reduce the potential for accidental releases

- Scheduling of regular inspection and maintenance of equipment.

Examples of surface releases that may occur include hydrocarbons (e.g., diesel, gasoline), drilling mud, saline water, and chemicals including H_2S Scavenger, clay stabilizer, and methanol. Appropriate mitigation measures for surface releases may include:

- Onsite personnel will receive appropriate operational and safety training for each task undertaken and will use appropriate PPE.
- Best management practices and safe operating procedures will be adhered to, to minimize risk of releases.
- Onsite staff will be trained in the emergency procedures in the event of a surface release.
- Catchment trays will be used at fluid transfer points to prevent surface releases.
- Fuels and chemicals will be properly contained and stored in compliance with legislation.
- WHMIS documents will be on site to support the proper storage, handling, usage, and treatment requirements.
- TDG regulations will be followed.
- All personnel handling and transporting fuels and chemicals will be trained in the proper handling (WHMIS training) and transportation (TDG training) of such fuels and chemicals.
- Spill kits will be readily available on site and personnel will follow the procedures in the Spill Response Plan in the EMP.
- Use of safety systems are expected to prevent or minimize release at source (e.g., automatic shut offs, flow restrictors).
- If a surface release occurs, contaminated materials will be removed from the environment in accordance with the appropriate legislation.

1.10.7 Blowouts

Blowouts are uncontrolled gas or fluid releases to the atmosphere and/or surface. They are rare in the Canadian oil and gas industry but can result in severe injury to workers or possibly death. The Blowout Plan mitigation and response measures will be included within a comprehensive HS/ERP which would be enacted to mitigate personnel safety incidents and effects on the environment in the unlikely event of a blowout. The Blowout Plan may include the following examples of mitigation and response measures:

- Onsite personnel will receive appropriate operational and safety training for roles performed.
- Onsite personnel will use appropriate PPE.
- Best management practices and safe operating procedures serve to minimize risk of releases.
- Proper installation, testing and use of blowout prevention equipment will be undertaken.
- Emergency procedures will be followed in the event of a blowout, including roles and responsibilities of personnel, communication protocols (including emergency notifications to authorities, First Nations, and hunters' and trappers' associations);
- Identification of service providers for each circumstance (e.g., to bring a blowout under control),
- Preparation of medical emergency plans including locations of the nearest hospital, alternative hospital, and transportation protocols.

Once the blowout is controlled, clean up procedures will be followed in accordance with the appropriate legislation to remove released fluids and contaminants for disposal at an approved waste handling facility and will be in accordance with the EMP.

1.10.8 Perforating

During the well completions (e.g., installation of well casing) and at other specific times, the use of explosive perforating charges may be required to punch holes in the casing into geological formations containing crude oil and/or natural gas to allow the controlled flow of oil and/or gas into the well bore and up to surface at the commencement of EFT activities. This activity carries a risk of detonation of explosives at surface. Appropriate mitigative measures for well completion activities including perforating will be included in the development of the Chance HS/ERP. Some examples of mitigation measures related to perforating include:

- All personnel handling and transporting explosives will receive the appropriate training (e.g., TDG training).
- Unnecessary personnel will be removed from the area during the arming of the explosive equipment.
- Safety meetings will be held to inform personnel of their responsibilities during the well completion process; safety meetings will be held at the start of this procedure and at a shift change.

1.10.9 Cementing

During the drilling and completion operations, cementing will be required to cement the casing in place or isolate productive zones from each other. During these operations, there is a risk of spilling cementing materials. Appropriate mitigative measures for well completion activities including cementing will be considered in the development of the Chance HS/ERP and the EMP which will include a Spill Response Plan. Some examples of mitigation measures related to cementing include the following:

- Onsite personnel will use appropriate PPE.
- Best management practices and safe operating procedures serve to minimize risk of releases.
- Appropriate personnel will receive WHMIS training and WHMIS documents will be accessible to support the proper storage, handling, usage, and treatment requirements.
- If a spill occurs, the material will be removed from the environment in accordance with required legislation and the Chance Spill Response Plan in the EMP.

1.10.10 Radioactive Well Logging

During the drilling and completions operations, downhole “logging” tools on wireline delivery into the well bore may be used to measure the properties of the various rock formations and any fluids that have accumulated in these formations. Some of these tools contain radioactive materials in trace quantities. The use of these tools creates a risk of exposure to radioactive materials or release of small amounts of radioactive material from failed equipment. Measures used to mitigate the risk of radioactive well logging will be included in the development of the Chance HS/ERP; some examples may include:

- All personnel handling the materials will have the proper training as required by Canadian Nuclear Safety Commission.
- Unnecessary personnel will be removed from the areas where radioactive materials are present.
- All radioactive materials will be stored in locked and access-controlled containers and in compliance with appropriate legislation.

1.10.11 Human-Wildlife Conflicts

Human-wildlife conflict occurs when encounters between humans (e.g., site workers) and local wildlife lead to negative results such as loss or damage of property, bodily injury to a worker or animal, and direct wildlife mortalities associated with vehicular accidents and equipment strikes. The risk of human-wildlife conflicts or dangerous encounters is increased by the presence of wildlife attractants such as food, cooking grease, and garbage.

Chance will take measures to prevent human-wildlife conflicts associated with Project activities such as use of vehicles, camp/kitchen operations and operation of heavy equipment and will include relevant mitigation measures in the development of the Chance EMP and associated Wildlife Management and Monitoring Plan. Examples of mitigation measures pertaining to human-wildlife conflicts may include:

- All roads will have controlled access off the Dempster highway (some will have gates, controlled access, and/or security).
- Any use of winter roads is to be managed with radio communication for traffic control, safety management and notices of wildlife encounters.
- Winter road usage will abide by posted speed limits which must be reduced when wildlife is encountered.
- Notable wildlife observations (e.g., large mammals) will be reported to the Wildlife Monitors who will record and communicate observations, in compliance with the Wildlife Management and Monitoring Plan.
- A Caribou Interaction Response Plan will be used when caribou are observed during Project activities (**Section 9**).
- High visibility tape will be placed, and regularly replaced as needed, on guy wires of equipment such as the flare stack to promote visibility to birds and other wildlife.
- Best practices including appropriate management of attractants such as food and cooking oil will be undertaken to reduce opportunity for human-wildlife conflicts or dangerous encounters, in accordance with *Guidelines for Industrial Activity in Bear Country* (Government of Yukon and Mining and Petroleum Environmental Research Group 2008).
- Refuse containers will be bear proof to prevent wildlife access. Garbage collection will be undertaken regularly and either burned at the incinerator at the Chance Camp or removed to an approved landfill site to reduce presence of wildlife attractants and reduce opportunity for human-wildlife conflicts or dangerous encounters.

Potential wildlife encounters, direct wildlife mortality risks, human-wildlife conflict and associated mitigations have also been discussed in **Section 8 Wildlife**, **Section 9 Caribou**, and **Section 12 Effects Management** and will be incorporated into the Project EMP and Wildlife Management and Monitoring Plan where appropriate.

1.10.12 General Safety

Chance will develop a Project-specific, comprehensive HS/ERP to complete all Project components in the safest manner possible. General safety measures to mitigate and respond to potential accidents and malfunctions will be developed and included in the HS/ERP. Some examples of general safety mitigation measures may include:

- At each shift change, safety meetings will be held with the incoming crew.
- All personnel will be required to wear proper PPE including protection for potentially extremely cold weather.
- All personnel will have the required training necessary to perform their duties. Some examples of training requirements are:
    - First Line Blowout Prevention;
    - Second Line Blowout Prevention;
    - Well Service Blowout Prevention;
    - TDG training;
    - WHMIS training;
    - Detection and Control of Flammable Substances training;
    - First Aid training (Standard and Emergency); and,
    - Common Safety Orientation (including extreme weather and temperature exposure safety).

A nurse practitioner will be on site (at the Chance Camp) at all times during the Project to support the timely treatment of any and all injuries due to the remoteness of exploration activities.

2 CONSULTATION AND ENGAGEMENT

Chance Oil and Gas Ltd. (Chance) is submitting the Eagle Plains Exploration Project (the Project) for review to Yukon Environmental and Socio-economic Board's (YESAB) Executive Committee (EC) for a screening. As per the *Yukon Environmental and Socio-economic Act (YESAA*) requirements, Chance has undertaken consultation and engagement activities with potentially affected First Nations and residents of communities. This Consultation and Engagement Section describes Chance's First Nations Consultation and Engagement Program (the Program) since Project initiation in 2014, up to December 20, 2023. This section describes the Program, including:

- information about potentially affected First Nations and residents of communities;
- consultation and engagement requirements for the Project;
- consultation and engagement principles and objectives;
- consultation and engagement with potentially affected First Nations and residents of communities during challenges to the Program, including COVID-19 and natural disasters; and,
- consultation and engagement activities with potentially affected First Nations and residents of communities from 2014 to December 20, 2023.

2.1 POTENTIALLY AFFECTED FIRST NATIONS AND RESIDENTS OF COMMUNITIES

The Program encompasses consultation and engagement with First Nations and residents of communities potentially affected by the Project. Potentially affected First Nations and residents of communities were identified as being potentially affected based on meeting one or more of the following criteria under the *YESAA*:

- The Project footprint (**Map 2-1**) overlaps with First Nations whose Traditional Territory, as defined by the *Umbrella Final Agreement* (UFA) and including Settlement Land and/or Non-Settlement Land and includes Lands within the *First Nation of Na-Cho Nyäk Dun Final Agreement*, *Gwich'in Comprehensive Land Claim Agreement*, and *Vuntut Gwitchin First Nation Final Agreement*;
- residents of a community that overlaps with the Project; or,
- First Nations and/or residents of a community who may experience significant environmental or socio-economic effects from the Project (Yukon Environmental and Socio-economic Assessment Board [YESAB] 2022).

Potentially affected First Nations and residents of communities consulted and engaged about the Project are listed below (alphabetically):

- First Nation of Na-Cho Nyäk Dun;
- Gwich'in Tribal Council, comprising:
  - Ehdiitat Gwich'in Council;
  - Gwichya Gwich'in Council (Tsiigehtchic);
  - Nihtat Gwich'in Council; and,
  - Tetł'it Gwich'in Council.

- Tr'ondëk Hwëch'in;
- Vuntut Gwitchin First Nation; and,
- Residents of Aklavik, Dawson City, Fort McPherson, Inuvik, Mayo, Old Crow, and Tsiigehtchic.

The Program includes consultation and engagement with potentially affected First Nation Citizens that live outside of administrative centres and reserves.

The Project overlaps the Traditional Territories of

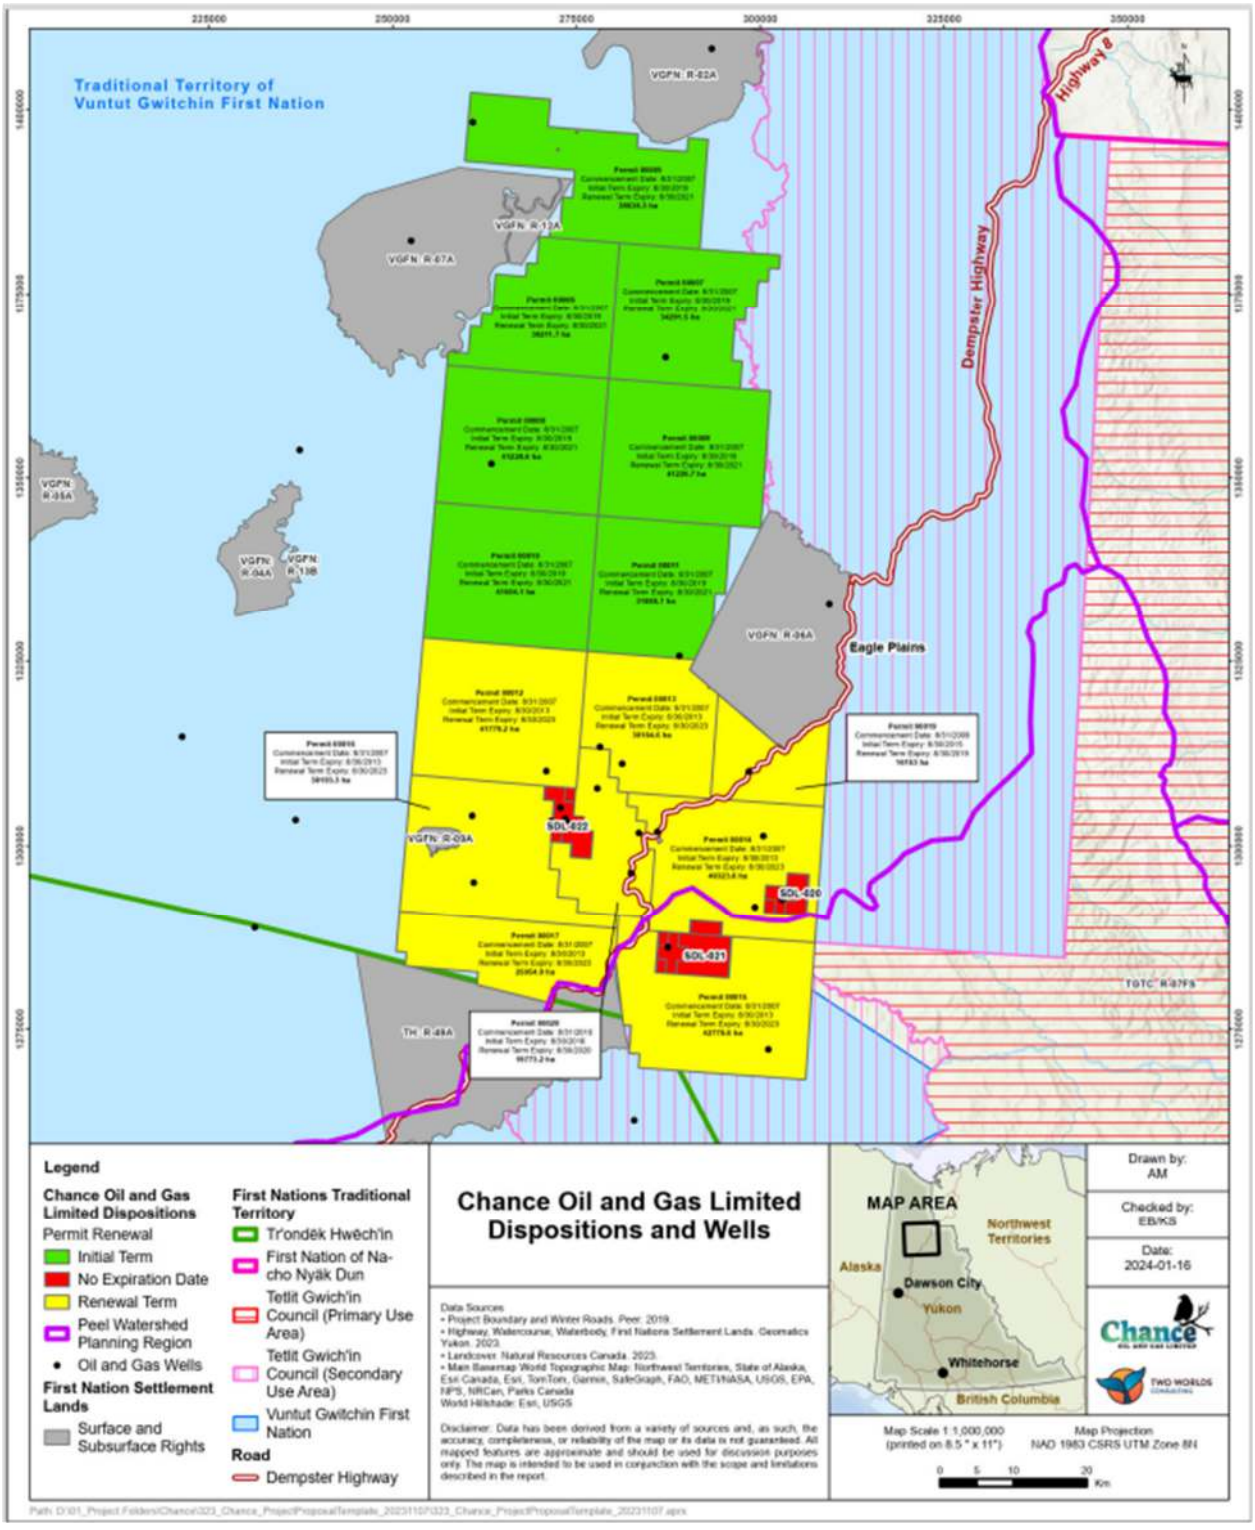
- First Nation of Na-Cho Nyäk Dun;
- Tetłʼit Gwichʼin Council; and,
- Vuntut Gwitchin First Nation.

Most of the Project is within the Traditional Territory of the Vuntut Gwitchin First Nation. The Project also overlaps small areas of the Traditional Territories of the First Nation of Na-Cho Nyäk Dun and Tetłʼit Gwichʼin Council. Tr'ondëk Hwëch'inʼs Traditional Territory does not overlap with the Project footprint but is adjacent to the southern edge of the Project.

The Project does not fall within any First Nation Settlement Lands but borders the east and southwest portions of the Vuntut Gwitchin First Nation Settlement Lands.

Since no residents of communities overlap with the Project footprint, residents of communities consulted and engaged on the Project were chosen based on the potential that they may experience significant environmental or socio-economic effects from the Project, and because the majority of potentially affected First Nation Citizens reside in these communities.

Map 2-1 shows the location of the Project within a larger permitted exploration area.



Map 2-1. Chance Oil and Gas Limited Dispositions and Wells

2.2 CONSULTATION AND ENGAGEMENT REQUIREMENTS

The Project is subject to a screening by the YESAB EC, as stated in the *Designated Office Evaluation Report*: *Eagle Plains Multi-Well Exploration Program* issued on February 9, 2016 (Project Number: 2014-0112). In addition to the YESAB EC screening, the Project also requires federal and territorial permits, licences, approvals, and assessments.

Proponent-led consultation is distinct from Crown requirements to consult First Nations (Government of Canada 2003a). The Crown has a duty to consult with affected First Nations about projects "and, where appropriate, to accommodate Indigenous groups [when] it considers conduct that might adversely affect potential or established Aboriginal or treaty rights" (Government of Canada 2023b). Chance is required to meet consultation requirements under Sections 3 and 50(3) of the *YESAA* (Government of Canada 2003). The *YESAA* requires Chance to consult with potentially affected First Nations and residents of communities prior to submitting its Project Proposal to the EC (Government of Canada 2003a).

Chance's engagement with potentially affected First Nations and residents of communities has and continues to be focused on meeting the following *YESAA* requirements:

- providing opportunities to share Project information, including information on potential Project-related effects to support potentially affected First Nations and residents of communities to prepare and present views about the Project; and,
- considering, fully and fairly, views presented by potentially affected First Nations and residents of communities about the Project.

This section describes Chance's activities through the Program to achieve these objectives. The Program was also developed to meet YESAB's consultation guidance outlined in the *Consultation Guidance for Proponents* and the *User Guide: Pre-Submission Engagement for Executive Committee Screenings* (Phase 6) (see **Figure 2-1**) (YESAB 2022).

Figure 2-1. Stages of 'Yukon Environmental and Socio-economic Assessment Board's Pre-Submission Engagement Process

2.3 CONSULTATION AND ENGAGEMENT PRINCIPLES AND OBJECTIVES

Chance strives to implement the following consultation and engagement principles during all Project-related consultation and engagement activities, based on YESAB guidance (Yukon Environmental and Socio-economic Board 2017):

- transparency and openness, which includes:

    - providing equal opportunity to access Project information; and,
    - making Project information to potentially affected First Nations and residents of communities available in a timely and digestible manner.
- adaptive management, which includes:
    - responding to First Nation and residents of communities' feedback; and,
    - mitigating, where possible, potential adverse Project-related effects on potentially affected First Nations and residents of communities.
- mutual respect, trust, and understanding which includes:
    - implementing consultation and engagement activities to support all potentially affected First Nations, residents of communities, and Chance working together; and,
    - creating opportunities for potentially affected First Nations and residents of communities to meaningfully understand and provide feedback about the Project.

Consultation and engagement objectives for the Project include:

- building collaborative relationships with potentially affected First Nations and residents of communities during all Project phases;
- developing a shared understanding of the Project with potentially affected First Nations and residents of communities;
- discussing potential Project-related effects, issues, and interests identified by potentially affected First Nations and residents of communities;
- potentially amending the Project design based on input and concerns from potentially affected First Nations and residents of communities; and,
- developing mitigation measures for potential Project-related adverse effects on potentially affected First Nations and residents of communities.

These objectives may evolve throughout the life of the Project in response to feedback from potentially affected First Nations and residents of communities.

2.4 OVERVIEW OF THE CONSULTATION AND ENGAGEMENT PROGRAM

Chance has undertaken consultation and engagement activities with potentially affected First Nations and residents of communities since 2014. Chance sought to solicit views, concerns, input, and feedback about the Project. However, various events and relationship constraints occurred between 2014 to 2023 that created barriers to the Program, such as:

- ability of potentially affected First Nations and residents of communities to participate in Project consultation and engagement activities; and,
- ability of potentially affected First Nations and residents of communities to share feedback about the Project.

This section provides an overview of the successes and challenges in the Program. Chance recognizes that First Nation governments and communities have faced capacity challenges and time and resource

constraints required to participate meaningfully in the Program. Chance acknowledges the importance of First Nations governments and communities having opportunities to provide feedback and be heard on their concerns related to the Project. Chance is committed to an engagement process that seeks to align with First Nation expectations, *YESAA* and related guidance, and best practices.

At a high level, the following timeline displayed in **Figure 2-2** shows important milestones in the Project and the Program up to submission of the Project Proposal in February 2024.

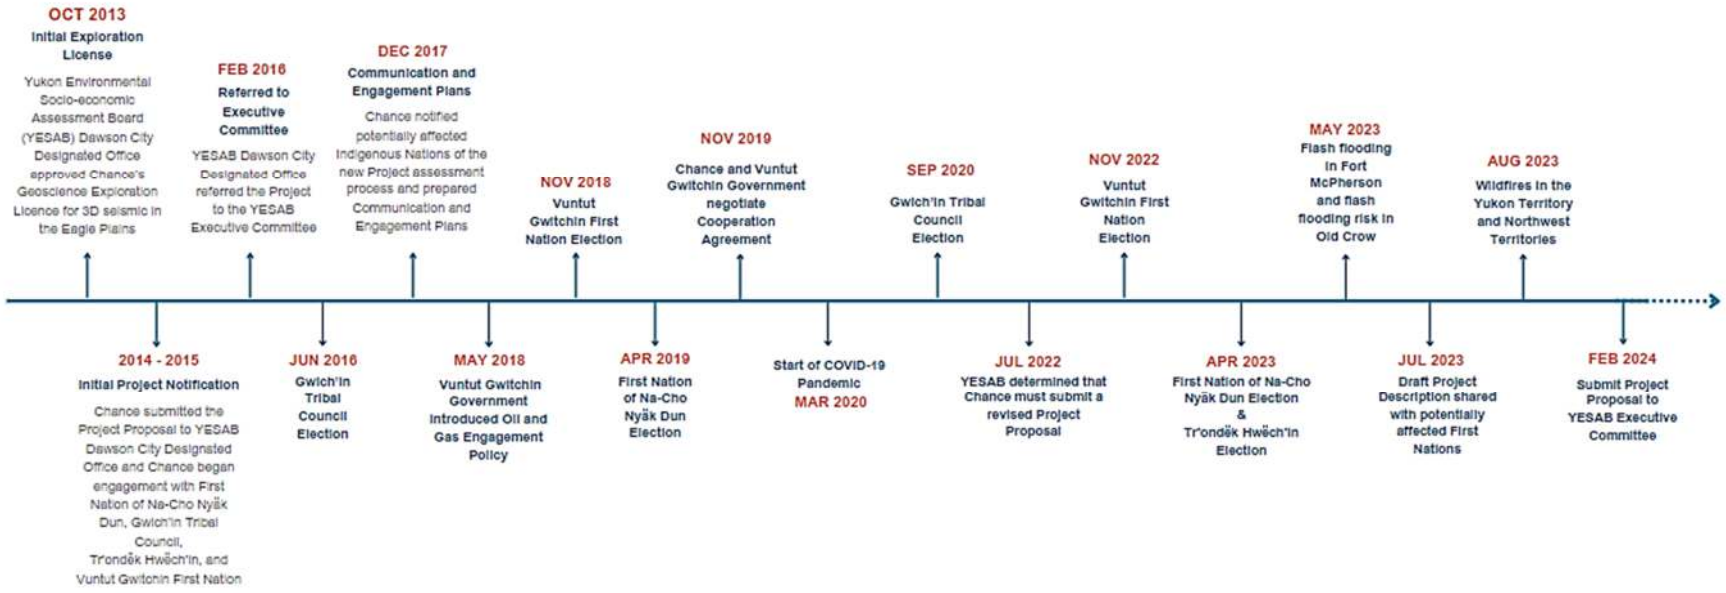


Figure 2-2. Milestones in Consultation and Engagement Related to the Eagle Plains Exploration Project

2.4.1 Yearly Summaries of Consultation and Engagement Activities and Events Shaping Involvement in the Program

This section summarizes consultation and engagement activities and events that shaped potentially affected First Nations and residents of communities' involvement in the Program.

2.4.1.1 2014

In July 2014, Northern Cross (Yukon) Limited, now named "Chance Oil and Gas Ltd", submitted a Project Proposal for the "Eagle Plains Multi-Well Exploration Program" for assessment by YESAB's Dawson City Designated Office (DO) (YOR# 2014-0112). The Project Proposal documents included a Project description, Project mapping and layout, a 2013 *Heritage Resource Impact Assessment* (*HRIA*), a 2013 *Heritage Resources Overview Assessment* (*HROA*), an *Emergency Spill and Response Plan*, an *Operational Plan*, an *Emergency Response Plan*, and a *First Nation Environmental Monitoring Plan*.

The Project assessment's first public comment period, which was extended by the Dawson City DO in response to extension requests from the Tetl'it Gwich'in Council, Vuntut Gwitchin First Nation, and First Nation of Na-Cho Nyäk Dun, was undertaken from October 30 to December 4, 2014 (inclusive of the extension) (YOR# 2014-0112-096-1). In 2014, the Dawson City DO put forward four Information Requests to Northern Cross Limited.

Chance-led consultation and engagement activities were paused during the public comment period.

2.4.1.2 2015

Throughout 2015, YESAB's Dawson City DO continued its assessment of Northern Cross (Yukon) Limited's "Eagle Plains Multi-Well Exploration Program" (YOR# 2014-0112). The Dawson City DO undertook an additional "Seeking Views and Information" stage, with a second public comment period from November 4 to December 9, 2015. The Dawson City DO held a public meeting in Dawson City during this time. On December 10, 2015, the Dawson City DO began preparing its recommendation, and extended the submission deadline five times between December 23, 2015, and February 9, 2016 (YOR# 2014-0112).

2.4.1.3 2016

In February 2016, YESAB's Dawson City DO released its evaluation report of the "Eagle Plains Multi-Well Exploration Program" (YOR# 2014-0112). As per s. 56(1)(d) the *YESAA,* the DO referred the Project to the EC for a screening, as it "could not determine whether the Project will have, or is likely to have, significant adverse socio-economic effects" (YOR# 2014-0112-274-1). This referral to a higher level of assessment requires Chance to submit more extensive information and involves additional and lengthier assessment steps.

In June 2016, the Gwich'in Tribal Council Election was held.

2.4.1.4 2017

In August 2017, Chance received renewal terms of exploration permits held by Chance (M.O. 2017/37). Yukon's *Oil and Gas Act*, section 14, requires consultation with Yukon First Nations to extend permits (Government of Yukon 2002).

In December 2017, Chance sent letters to Vuntut Gwitchin First Nation, Tetl'it Gwich'in Council, First Nation of Na-Cho Nyäk Dun, and Tr'ondëk Hwëch'in providing notification of the Project and requesting the development of a *Communication and Engagement Plan* in partnership with each First Nation.

2.4.1.5 2018

In January 2018, Vuntut Gwitchin First Nation transmitted its preliminary *Oil and Gas Engagement Policy* to Chance via email. This policy, officially disclosed to the public in May 2018, serves the purpose of "establishing a respectful, transparent, and meaningful framework" to govern consultation and engagement between the Vuntut Gwitchin First Nation and oil and gas proponents (Vuntut Gwitchin Government 2018). The document outlines the Vuntut Gwitchin First Nation's procedural approach for proponents to engage with its Citizens concerning oil and gas activities and dispositions.

In May 2018, Chance and First Nation of Na-Cho Nyäk Dun began developing the First Nation of Na-Cho Nyäk Dun and Chance Oil and Gas Limited Engagement and Consultation Plan.

In May 2018, Chance received extensions to renewal terms of exploration permits 0012-0017 held by Chance Oil and Gas Ltd. (M.O. 2018/42). Yukon's *Oil and Gas Act*, Section 14, requires consultation, including the development of communication and engagement plans, with Yukon First Nations to extend permits (Government of Yukon 2002).

In May 2018, the Vuntut Gwitchin First Nation publicly introduced its *Oil and Gas Engagement Policy*.

In August 2018, the Gwich'in Partners and Chance Oil and Gas Limited Communications and Consultation Plan was finalized.

In November 2018, the Vuntut Gwitchin First Nation election was held.

2.4.1.6 2019

In April 2019, the First Nation of Na-Cho Nyäk Dun election was held.

In November 2019, Chance and Vuntut Gwitchin First Nation met with a facilitator to negotiate a Cooperation Agreement required under Stage II of the *Vuntut Gwitchin Government Oil and Gas Engagement Policy*. The objectives and content of the Cooperation Agreement were discussed.

In August 2019, Chance was granted an extension to the renewal terms of oil and gas permits 0008-11 and 0019 held by Chance Oil and Gas Ltd. (M.O. 2019/27). Yukon's *Oil and Gas Act*, Section 14, requires consultation with Yukon First Nations to extend permits (Government of Yukon 2002).

2.4.1.7 2020

In February 2020, Chance requested an exemption from Vuntut Gwitchin First Nation under the *Vuntut Gwitchin Government Oil and Gas Engagement Policy* and the *Benefits and Stewardship Agreement* to accelerate entry into the *YESAA* process, given the tenure of existing exploration permits. Specifically, Chance wished to enter the *YESAA* process while simultaneously engaging Vuntut Gwitchin First Nation regarding the *Vuntut Gwitchin Government Oil and Gas Engagement Policy*. Vuntut Gwitchin First Nation advised Chance that their request for a waiver of the requirement under the *Vuntut Gwitchin Government Oil and Gas Engagement Policy* had not been granted by the Vuntut Gwitchin First Nation Natural Resources Committee.

In March 2020, the Government of Yukon declared a state of emergency at the start of the COVID-19 pandemic (McPhee-Knowles, Hoffman, and Kanary 2022). Chance's Program changed in response to COVID-19 protocols, processes, and preferences established by potentially affected First Nations, Government of Yukon, and the Government of Canada. Changes included pausing and rescheduling in-person consultation and engagement activities and focusing on virtual consultation and engagement methods, respecting safe distance and mask-wearing protocols during in-person meetings, as well as adapting and responding to ongoing requests from potentially affected First Nations and communities. Chance also developed a *COVID-19 Community Engagement and Consultation Procedures* document. Additional information on the impact of COVID-19 on potentially affected Indigenous Nations and the Program is described in **Section 2.5.1**.

- In December 2020, Chance submitted the Eagle Plains Well Maintenance and Exploration application to the Dawson City DO (YOR# 2020-0197). This involved the maintenance of 8 suspended oil and gas wells, extended flow testing (EFT) on 3 wells, the conversion of 2 wells to deep-injection wells for disposal of waste borehole fluids, and the abandonment of up to 6 wells[2] as part of the Project.

In August 2020, Chance was granted an extension to the renewal terms of oil and gas permit 0020 (M.O. 2020/55). As per Section 14 of the Yukon's *Oil and Gas Act*, consultation is required with Yukon First Nations to extend permits (Government of Yukon 2002).

In September 2020, the Gwich'in Tribal Council Election was held.

2.4.1.8 2021

While the Yukon received its first shipment of vaccine doses in January 2021, the effects of the COVID-19 pandemic continued to affect communities and First Nations throughout 2021. For example, until the end of May 2021, outside of territory travel for vaccinated individuals required a 2-week self-isolation upon return (McPhee-Knowles, Hoffman, and Kanary 2022).

In March 2021, Vuntut Gwitchin First Nation sent a letter to Chance expressing concerns about perceived non-compliance with their *Oil and Gas Engagement Policy* and the *Communication and Engagement Plan*. Consequently, Vuntut Gwitchin First Nation decided to pause communications with Chance temporarily, pending an internal review of the Vuntut Gwitchin First Nation's *Oil and Gas Engagement Policy*'s alignment with Chance's *Communication and Engagement Plan*. Future consultations would be discretionary on the part of the First Nation and would be by invitation only.

In April and May of 2021, Chance hosted two open house events in Old Crow and provided a Project overview including information on wildlife studies, historical linear features in Eagle Plains, water quality and other ecological data, and drilling.

In October 2021, Chance hosted an open house in Old Crow to discuss permafrost, seismic, and wildlife baseline studies.

[2] "When a company no longer needs a well to support its oil and gas development, the well must be permanently sealed and taken out of service. This part of the closure process is known as abandonment" ("How Are Wells Abandoned?" 2020).

2.4.1.9 2022

In May 2022, Chance held two community open house events in Old Crow to share Project information including details on the drilling program, heritage resources, permafrost, seismic testing, and wildlife studies.

In July 2022, YESAB determined that Chance must submit a revised Project Proposal.

In August 2022, Chance was granted extensions to its renewal terms of oil and gas permits 0010 and 0011 by the Government of Yukon (M.O. 2022/47). The Yukon's *Oil and Gas Act,* Section 14, requires consultation with Yukon First Nations to extend permits (Government of Yukon 2002).

In September 2022, the Chiefs of Vuntut Gwitchin First Nation, Tr'ondëk Hwëch'in First Nation, and First Nation of Na-Cho Nyäk Dun released a joint statement opposing the approved extension of two of Chance's permits to 2027. The Chiefs noted that development within their Traditional Territories creates barriers to achieving climate change mitigation goals, sustainable development, and protecting the culturally significant Porcupine Caribou Herd (PCH) that lives throughout the Eagle Plains region. Chance did not formally respond to this joint statement, however, continued to be available to discuss Chance permits directly with potentially affected First Nations, if interested.

In November 2022, the Vuntut Gwitchin First Nation election was held, and leadership changed.

2.4.1.10 2023

In January 2023, Chance hosted an in-person meeting in Vancouver, British Columbia (BC) with the Chiefs, staff, and technical advisors of potentially affected First Nations to re-establish collaborative working relationships, discuss consultation and engagement preferences, and to provide a Project update. Chief Frost from Vuntut Gwitchin First Nation shared concerns about and the importance of being more confident in numbers and determinations in the YESAB consultation and engagement process. Chief Frost also expressed that the northern First Nations want to participate collaboratively in the Project to ensure it is well managed and not going to create long-term environmental degradation. Chief Frost said the northern First Nations will share their interests and concerns with Chance and stop the consultation and engagement process from advancing if it does not consider local Indigenous Knowledge.

In April 2023, both the First Nation of Na-Cho Nyäk Dun and Tr'ondëk Hwëch'in held council elections. Chance sent letters to both governments and requested to meet and discuss the Project.

In May 2023, Chance travelled to Old Crow to conduct a community open house event with Vuntut Gwitchin First Nation Citizens and residents of Old Crow. High streamflow advisories were issued by the Government of Yukon due to ice jams on both the Porcupine and nearby Old Crow rivers. This event was cancelled due to a flash flooding risk.

In May 2023, Chance held a Project overview community open house with Gwich'in Participants and residents of Inuvik at the Nihtat Gwich'in Council Board Room in Inuvik.

In May 2023, Chance met with Grand Chief Ken Kyikavichik (Gwich'in Tribal Council), and the Gwich'in Development Corporation to discuss Project updates, consultation and engagement preferences, and an overview of the open house in Inuvik with Gwich'in Participants and residents of Inuvik.

In May 2023, there was a flash flooding event in Fort McPherson. The Peel River flooded the Dempster Highway and cut off access to the airport. Concurrently, there was a death in the community. Chance cancelled a community open house event in response to these circumstances.

In June 2023, Chance submitted the application for the *Eagle Plains Camp: For Well Inspection and Maintenance* project to YESAB's Dawson City DO (YOR# 2023-0099). Project activities for this application included operation of the existing Chance main camp for five consecutive years for a 4-week period between mid-June and mid-August, if approved. Well site inspections (3 by road and 5 by helicopter) would occur at 8 well site locations. Within that 5-year period, the camp would be opened for two winter seasons between the months of early November to mid-April to support well maintenance at the 8 well sites.

In July 2023, Chance shared the *Draft Project Description* with potentially affected First Nations.

In August 2023, Chance met with technical advisors on behalf of First Nation of Na-Cho Nyäk Dun, Tr'ondëk Hwëch'in, and Vuntut Gwitchin First Nation to discuss the *Draft Project Description* and proposed consultation and engagement activities with each First Nation.

In August 2023, multiple wildfires occurred across the Yukon and the Northwest Territories (NWT). The 2023 wildfire season was Canada's most severe on record. Effects from wildfires included an evacuation order, implementing emergency response plans, loss of power, infrastructure damage, and adverse effects on human health. Chance shifted its Program in response to natural disasters and emergency response measures implemented by each First Nation and community. For example, Chance rescheduled 2 community open house events planned for Fort McPherson and Old Crow from August to September 2023.

In August 2023, Chance met virtually with potentially affected First Nations and YESAB to discuss the Project's assessment process. YESAB confirmed the Project's assessment would begin at Stage 6 of the EC's Pre-Submission Engagement (PSE) Process (See **Figure 2-1**).

In August 2023, Chance was granted extensions to its renewal terms of oil and gas permits 0012-0017 and 0019-0020 (M.O. 2023/38). Yukon's *Oil and Gas Act*, Section 14, requires consultation with Yukon First Nations to extend permits (Government of Yukon 2002).

In August, September, and October 2023, Chance met virtually with Gwich'in Tribal Council staff to discuss the Project and proposed consultation and engagement activities.

In October 2023, Chance, potentially affected First Nations, Government of Canda, YESAB, and Government of Yukon met virtually to discuss the Project's assessment process, capacity funding, and possible efficiencies through a coordinated approach (e.g., sharing consultants to support potentially affected First Nations' review of the Project Proposal).

In December 2023, Chance held community open house events in Fort McPherson and Old Crow. Chance held a World Café event[3] in Old Crow to share information on potential Project-related effects and proposed mitigation measures to support Vuntut Gwitchin First Nation Citizens and residents of Old Crow to prepare views about the Project. This event provided an opportunity for Vuntut Gwitchin First Nation Citizens and residents of Old Crow to provide feedback on consultation and engagement, potential Project-related

[3] A World Café event is an engagement method that creates an informal method of discussion. Participants are separated into smaller groups to discuss different subjects.

effects, general Project-related concerns, and proposed mitigation measures. Chance held a hybrid online and in-person open house event in Fort McPherson to provide a Project overview to Gwich'in Participants and residents of Fort McPherson, Tsiigehtchic, and Aklavik. This event provided an opportunity for Gwich'in Participants and residents of Fort McPherson to prepare and share views about the Project.

In December 2023, Chance held a hybrid online and in-person technical working group meeting with a technical advisor for First Nation of Na-Cho Nyäk Dun and Tr'ondëk Hwëch'in, a technical advisor for Vuntut Gwitchin First Nation, the Porcupine Caribou Management Board, and the Government of Yukon to share information and receive feedback about the Project's wildlife studies (notably the PCH) including baseline conditions, potential Project-related effects, and proposed mitigation measures. Chance invited all potentially affected First Nations to a hybrid technical working group meeting on heritage resources and permafrost on January 16, 2024[4].

2.5 EFFECTS ON THE CONSULTATION AND ENGAGEMENT PROGRAM

From 2014 to 2023, numerous events hindered active consultation and engagement activities between Chance, and potentially affected First Nations and residents of communities. Chance also acknowledges that during this time, there were periods of strained relationships with potentially affected First Nations and residents of communities. The following sections describe key challenges and opportunities to the Program since Project initiation.

2.5.1 Navigating Collaboration: Consultation and Engagement During the COVID-19 Pandemic and Natural Disasters

Rural communities encounter unique obstacles when it comes to accessing health and social services, which are more easily accessible in larger urban centres (e.g., Whitehorse and Yellowknife). Consequently, these communities responded quickly and with abundance of caution to the start of the COVID-19 pandemic in March 2020. Potentially affected First Nations and residents of communities were affected by the pandemic, with many requiring the reprioritization of limited resources to protect individual and community health and well-being (Auditor General of Canada 2023). Actions to protect communities included cancelling events, restricting visitors, and redirecting resources to develop risk mitigation policies and monitor outbreaks (Vuntut Gwitchin Government 2021a; 2021b; MacIntyre 2020). In March 2020, the Chief of First Nation of Na-Cho Nyäk Dun called for mining activities to pause due to concerns that fly-in workers would pose an exposure risk to the community (Rudyk 2020).

Restrictions on gathering sizes constrained potentially affected First Nation governments' capacity to internally meet and review information shared by Chance (Auditor General of Canada 2023). Chance's Program changed in response to COVID-19 protocols, processes, and preferences established by potentially affected First Nations, Government of Yukon, and the Government of Canada. Changes included pausing and rescheduling in-person consultation and engagement activities and focusing on virtual

[4] Meeting summaries for the technical working groups in December 2023 and January 2024 were not available at the time this chapter was drafted.

consultation and engagement methods, respecting safe distance and mask-wearing protocols during in-person meetings, as well as adapting and responding to ongoing requests from potentially affected First Nations and communities as needed. Chance acknowledges and appreciates potentially affected First Nations' commitment to engagement and consultation despite the circumstances introduced by the COVID-19 pandemic.

During this time potentially affected First Nations and residents of the associated communities were also affected by natural disasters. Notably, in 2023, potentially affected First Nations and residents of communities were affected by potential and actual flooding events, as well as wildfires. Effects from natural disasters included an evacuation order, implementing emergency response plans, loss of power, infrastructure damage, and effects on human health. Chance shifted its Program in response to natural disasters and emergency response measures implemented by each First Nation and community. For example, Chance rescheduled 2 community open house events planned for Old Crow in May 2023 and August 2023 to September 2023.

Sections 2.7 to **2.10** summarize consultation and engagement activities with potentially affected First Nations and residents of communities. These sections are presented in alphabetical order.

2.5.2 Vuntut Gwitchin Government's *Oil and Gas Engagement Policy*

Vuntut Gwitchin First Nation's *Oil and Gas Engagement Policy* came into force in May 2018. The policy serves the purpose of "establishing a respectful, transparent, and meaningful framework" to govern consultation and engagement between the Vuntut Gwitchin First Nation and oil and gas Proponents (Vuntut Gwitchin Government 2018). The document outlines the Vuntut Gwitchin First Nation's procedural approach for Proponents to engage with its Citizens concerning oil and gas activities and dispositions.

In March 2021, Vuntut Gwitchin First Nation sent a letter to Chance expressing concerns about perceived non-compliance with their *Oil and Gas Engagement Policy* and the *Communication and Engagement Plan*. In the letter, Vuntut Gwitchin First Nation said they perceived that engagement activities fell short of constituting consultation. Vuntut Gwitchin First Nation stressed the importance of Chance adhering to the principles of free, prior, and informed consent in relation to the Project.

Vuntut Gwitchin First Nation then suspended communications with Chance, pending an internal review of the *Oil and Gas Engagement Policy*'s alignment with the *Communication and Engagement Plan*. Future consultations would be discretionary on the part of the First Nation and would be by invitation only.

In September 2022, the Chiefs of Vuntut Gwitchin First Nation, Tr'ondëk Hwëch'in First Nation, and First Nation of Na-Cho Nyäk Dun released a joint statement opposing the approved extension of two of Chance's permits to 2027. The Chiefs noted that development within their Traditional Territories creates barriers to achieving climate change mitigation goals, sustainable development, and protecting the culturally significant PCH that lives throughout the Eagle Plains region (see **Section 8** of the Project Proposal documents for more information). Chance did not formally respond to this joint statement, however, continued to be available to discuss its permits directly with potentially affected First Nations, if interested.

Chance followed up with Vuntut Gwitchin First Nation to request re-engagement. Since the election of Chief Frost in 2022, Chance and Vuntut Gwitchin First Nation have moved forward with consultation and engagement, resulting in more active consultation and engagement activities. Chance has met with elected

Vuntut Gwitchin Government representatives, met with Vuntut Gwitchin First Nation technical advisor and staff, and was invited to host two community events with Vuntut Gwitchin Fist Nation Citizens.

Moving forward, Chance is committed to following consultation and engagement guidelines and protocols established by Vuntut Gwitchin First Nation, and to follow consultation and engagement guidelines and protocols outlined by all potentially affected First Nations. Chance continues to refine the Program in response to feedback shared from potentially affected First Nations. Chance strives to provide information with sufficient time to review, create opportunities to receive and respond to questions, feedback, and concerns, and to carefully consider all feedback from potentially affected First Nations and residents of communities.

2.5.3 Relationship-Building

The process of change in government is a multifaceted undertaking that involves political, administrative, legislative, and societal dimensions. Complexity arises from the need to address numerous issues, engage with various stakeholders, and implement changes in a systematic and responsible manner. After elections, the dynamics between companies and governments undergo a transformation, marked by the need for building relationships and familiarizing new council members with the essential aspects of proposed projects. Cultivating these new relationships takes time, which requires additional consultation and engagement activities.

Potentially affected First Nations' elected governments have changed since the Project was initiated in 2014. Since February 2016, when the Project was referred to an EC screening by the Dawson City DO, there have been seven elections within the governments of potentially affected First Nations (see timeline in **Section 2.4**). With every election, Chance has responded by connecting with newly formed governments to reintroduce the Project and consultation and engagement activities.

Chance is committed to respectfully consulting and engaging with all current and future First Nation governments of potentially affected First Nations. Prior to moving forward with community-level consultation and engagement activities, Chance will request feedback from potentially affected First Nations' governments on the preferred level and methods of involvement in the Project's assessment process, the Project, and Project-related consultation and engagement activities.

Sections 2.7 - **2.10** summarize consultation and engagement activities with potentially affected First Nations and residents of communities. These sections are presented in alphabetical order.

2.5.4 Consultation and Engagement Record Management and Legislative Requirements

Consultation and engagement requirements and best practices have evolved since the Project was initiated in 2014 (e.g., tracking and reporting expectations). The Project was initially developed to comply with the DO level assessment's consultation and engagement tracking and reporting requirements. After the Dawson City DO referred the Project to an EC screening, Chance was required to complete additional work to fulfill EC consultation and engagement tracking and reporting requirements. The introduction of the new assessment process led to Project delays, including delays to Project-related consultation and engagement and the development of the Project Proposal, while Chance navigated unfamiliar requirements, provided

additional information requested by assessment authorities, and aligned their application with the revised assessment criteria.

In 2023, YESAB determined that the Project would be advanced to Phase 6 of the EC's new PSE Process (See **Figure 2-1**). This required Chance to amend and update its consultation and engagement record for the Project in accordance with YESAB's *Consultation Guidance for Proponents*.

The record of contact with potentially affected First Nations and residents of communities includes all available records as of December 20, 2023.

2.5.5 Moving Forward: Consultation and Engagement Next Steps

Chance recognizes that additional challenges may affect its ability to consult and engage in the most effective way with potentially affected First Nations and residents of communities. However, Chance is committed to continuing to work with, and to have open dialogue with, potentially affected First Nations and communities throughout all stages of the Project. This includes providing information, giving sufficient time for review and consideration, accepting feedback, and taking input into consideration. Additionally, Chance will follow consultation and engagement guidelines and protocols established by potentially affected First Nations, Government of Yukon, and the *YESAA.*

While Chance has submitted its Project to the EC, it will continue its efforts to consult and engage with potentially affected First Nations and residents of communities. At the same time, Chance will be following the EC screening closely, tracking and taking into consideration all comments received by the EC during the assessment process. Chance may consult and engage with potentially affected First Nations and residents of communities to further understand comments, concerns, and/or questions shared with or by the EC.

2.6 RESULTS OF CONSULTATION AND ENGAGEMENT

In January 2023, Chance reinitiated consultation and engagement activities with potentially affected First Nations. Chance sought to establish positive and collaborative relationships that would continue through the YESAB EC screening assessment process and into future Project phases, if approved. Consultation and engagement activities between 2014 and 2023 included ongoing Project communications and updates via email, phone call, and text message, community open house events, virtual and in-person meetings, and document sharing. Chance shared an updated *Draft Project Description* with potentially affected First Nations in July 2023. Consultation and engagement activities since July 2023 focused on developing a shared understanding of the Project; specifically, how the Project design has changed in response to First Nation and resident of communities' feedback from 2014 to 2023. Chance provided opportunities to discuss and share information about the Project, Project-related effects, and mitigation measures with potentially affected First Nations and residents of communities. Chance also created opportunities for Chance, potentially affected First Nations, YESAB's EC, and Government of Yukon to meet collectively to develop a shared understanding of the screening process and discuss opportunities to support potentially affected First Nations' involvement in the Project's assessment process.

Feedback shared by potentially affected First Nations and residents of communities, and how Chance has responded and adapted the Project to feedback shared, is outlined in **Table 2-1**.

Table 2-1. Key Feedback Shared from 2014 to the Present

First Nation and Residents of Communities' Feedback	Chance's Response to Feedback Shared
Importance of land, water, and resources to First Nation culture and way of life	Chance recognizes and values the culture and way of life of First Nations and appreciates the First Nations' connection to the land. Chance modified the Project design to reduce potential Project-related effects on land, water, and resources. This includes spreading Project activities over 10 years to reduce annual environmental effects, optimizing the location of Project activities to avoid sensitive features, and scheduling most work during the winter. Additionally, Chance will implement mitigation measures, management plans, and a monitoring program to further reduce potential Project-related effects.
Concern for potential Project-related effects on the PCH	Chance has modified the original Project design submitted to the Dawson City DO to reduce potential Project-related effects on the PCH. This includes the modifications identified in Chance's response to feedback shared on the importance of land, water, and resources to First Nation culture and way of life (above), focusing many activities on previously disturbed areas and access networks to the extent possible, and implementing horizontal and directional drilling techniques to allow Chance to locate drilling locations to avoid sensitive and land and resource use activities as needed.
Importance of the PCH for cultural continuity, food, and other traditional purposes	Chance recognizes the importance of the PCH for cultural continuity, food, and other traditional purposes. Chance is committed to minimizing negative effects on the communities and First Nations who rely on the PCH by reducing potential effects on the herd as described in Chance's response to feedback shared on the concern for potential Project-related effects on the PCH.
Concern for negative effects on watercourses and wetlands	Chance conducted additional baseline studies in 2018/19 to understand potential Project-related effects on waterbodies and wetlands and shared relevant studies with interested First Nations. Additionally, Chance will optimize the location of activities that have the potential to affect waterbodies by minimizing the placement of winter roads and well sites, avoiding riparian areas and implementing mitigation measures, management plans, and on-site environmental monitoring.
Concern for seismic line clearing effects on predator-prey relationships and visual effects on people driving on the Dempster Highway	Chance proposes using low-impact seismic techniques and primarily winter seasonal activities to reduce seismic lines' functional and visual effects. This includes using dog leg designs where seismic lines cross the Dempster Highway, narrow seismic lines, and line construction that meanders across the land instead of being straight.
Concern regarding effects on permafrost	Chance conducted additional baseline studies in 2018/19 and 2022/23 to understand potential Project-related effects on permafrost and shared relevant studies with interested First Nations.
The perception that the Project involved fracking	Chance confirmed that fracking is not part of Project activities. If sufficient oil and/or natural gas resources are discovered, Chance may propose to conduct a future extraction project. Any future extraction project would undergo an environmental assessment. There is currently no plan for a future extraction project.
Interest in contributing to Project heritage studies	Chance shared heritage studies with potentially affected First Nations and committed to notifying potentially affected First Nations immediately if heritage resources are discovered. Chance will invite potentially affected First Nations to involve Citizens in heritage fieldwork studies. These studies are

First Nation and Residents of Communities' Feedback	Chance's Response to Feedback Shared
	partly investigative, but also demonstrative of how heritage work is done and how it can influence the Project.
Interest in employment, training, and procurement opportunities	Chance proposes to spread Project activities across a period of up to 10 years to create longer/steadier employment opportunities and to host career fairs. During its last drilling/seismic program, Chance successfully hired workers from the communities of Old Crow, Fort McPherson, Dawson, Whitehorse, and Inuvik.
Concern about lack of involvement in Project planning and mitigation development	Chance confirmed its willingness to continue discussing expected Project activities, potential Project-related effects, and mitigation measures with potentially affected First Nations and residents of communities.
Concern about Project-related potential effects on climate change	Chance shared that the long-term intent of the Project is to define a local source of oil and gas and reduce the overall carbon footprint of fuel consumption in the Yukon and neighbouring jurisdictions. Chance shared that the Project is explorative in nature, so the only emissions are connected to fuel consumption for camp operations, transportation of goods and services, exploration activities which includes potential for flaring during flow testing, and seismic programs. An estimate of this is pending.
Concern regarding cumulative effects	Chance conducted a *Linear Features Study* of the functional effect of existing linear features in the Project footprint, focused on wildlife, which was shared with interested First Nations. The Project effects assessment includes an evaluation of the creation of new linear features, as well as an assessment of cumulative effects to which the Project may contribute. The Project is focused on newer, low-impact seismic technology.
Concern about temporary and permanent Project roads	Chance modified the Project design to change from using year-round permanent roads to winter ice roads. Chance will restrict public access to roads.
Concern about year-round drilling	Chance switched the Project design from year-round to winter-only drilling activities.
Concern regarding non-compliance with Vuntut Gwitchin First Nation's *Oil and Gas Engagement Policy*	Chance acknowledges that there were challenges with its early engagement activities and aligning them with the Vuntut Gwitchin First Nation's *Oil and Gas Engagement Policy*. Chance confirmed its willingness to continue discussing Project activities, potential Project-related effects, and mitigation measures with potentially affected First Nations and residents of communities.

2.7 CONSULTATION AND ENGAGEMENT WITH FIRST NATION OF NA-CHO NYÄK DUN AND RESIDENTS OF MAYO

Section 2.7 outlines consultation and engagement activities with First Nation of Na-Cho Nyäk Dun and residents of Mayo. Information on Project notification, consultation and engagement planning, methods, activities, and agreements, issues, interests, and feedback shared through consultation and engagement activities are described in **Sections 2.7.1 – 2.7.9**.

2.7.1 Community Profiles

The following subsections describe First Nation of Na-Cho Nyäk Dun and the community of Mayo.

2.7.1.1 First Nation of Na-Cho Nyäk Dun

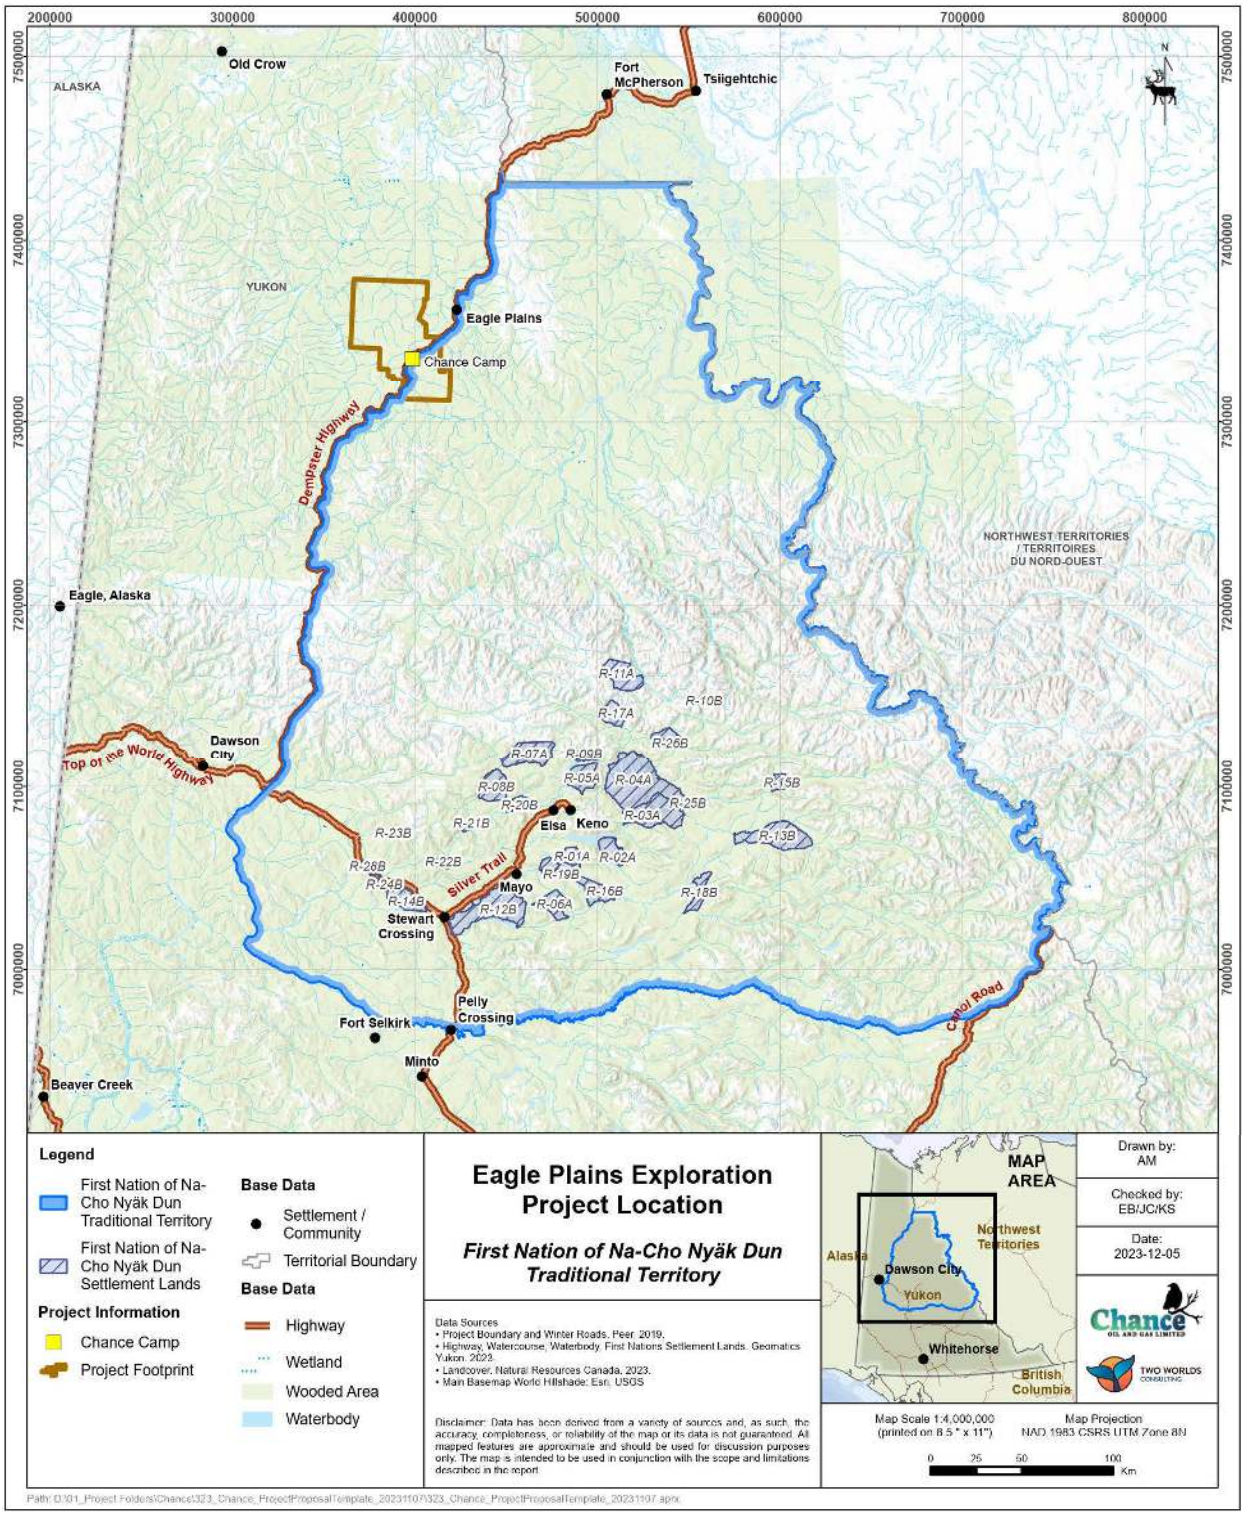
> "First Nations people have lived in our Traditional Territory since time began. Historically our ancestors lived on the land, maintaining a balance between the environment, the animals and our people." (Peter, Hogan and the First Nation of Na-Cho Nyäk Dun Lands Department 2006)

Na-Cho Nyäk Dun, means the Big River People in Northern Tutchone (Fred 2010). Na-Cho Nyäk Dun people are culturally affiliated with Northern Tutchone people of Selkirk First Nation and Little Salmon Carmacks First Nation (McClellan 2015).

The First Nation of Na-Cho Nyäk Dun has promoted the use of their traditional language and created initiatives including online Northern Tutchone language training for names of places, household items, and emotions to revitalize the use of the language within their community (First Nation of Na-Cho Nyäk Dun Elders et al. 2019).

> "Language can permeate every part of life in the community… There is no doubt the language we use is influential in who we are and how we think. Currently, our Northern Tutchone language has fallen into disuse. We don't use it because we don't know it, and we don't know it because there are no apparent benefits. To re-awaken the language, we have to teach it and make it a viable option, and then we have to follow that with the motivation to learn and use the language." (First Nation of Na-Cho Nyäk Dun 2023).

The First Nation of Na-Cho Nyäk Dun's Traditional Territory spans 162,456 kilometres square (km^2) in the Yukon and the NWT and overlaps with the Village of Mayo (326 kilometres (km) north of Whitehorse). First Nation of Na-Cho Nyäk Dun's Traditional Territory extends east to west from the NWT border to the Dempster Highway in the Yukon, and south to north from the Macmillan River to the Teetł'it Gwinjik (Peel River) watershed (**Map 2-2**). Additionally, the First Nation has an unsettled claim, which is currently being negotiated after the signing of a Framework Agreement in 2015, with the Government of Northwest Territories regarding potential transboundary territory (Government of Northwest Territories n.d.).



Map 2-2: First Nation of Na-Cho Nyäk Dun Traditional Territory

First Nation of Na-Cho Nyäk Dun's total registered population[5] as of November 2023 was 551 Citizens, (Government of Canada 2021). The First Nation is part of the *Umbrella Final Agreement* and signed its Self-Government Agreement in 1993 (Government of Canada 1993). First Nation of Na-Cho Nyäk Dun owns or manages 2,408.69 km^2 of Category A Lands and 4,748.95 km^2 of Category B Lands (Government of Canada 1993).

First Nation of Na-Cho Nyäk Dun's governance structure includes the Assembly and Council (Na-Cho Nyäk Dun 2009). The Assembly comprises all First Nation of Na-Cho Nyäk Dun Citizens who are 16 years of age or older (Na-Cho Nyäk Dun 2009). The Council is composed of a Chief, Deputy Chief, four councillors, 1 Elder Councillor, and one Youth Councillor. **Figure 2-3** outlines the Council's governance structure.

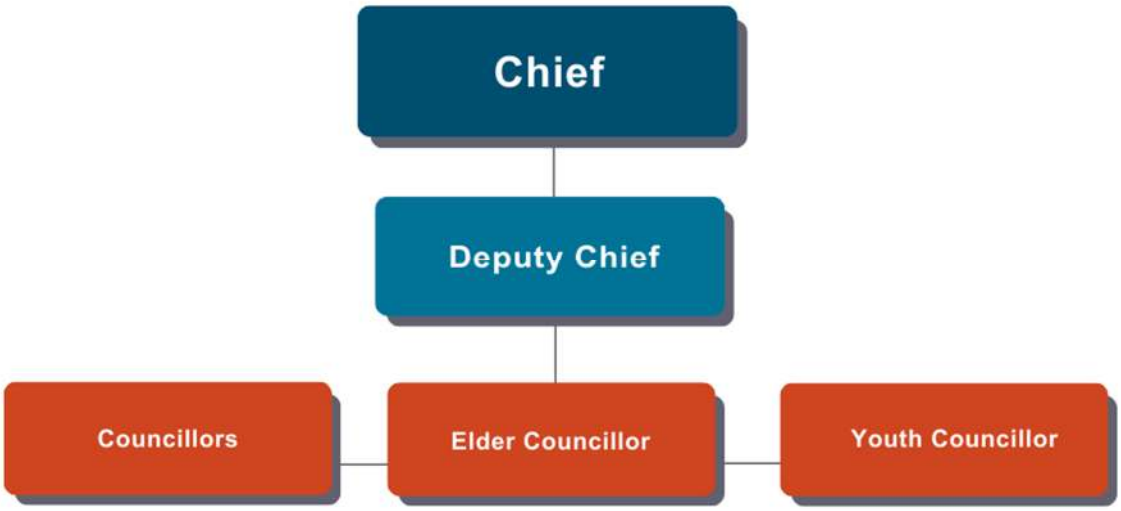


Figure 2-3. First Nation of Na-Cho Nyäk Dun Governance Structure

The Council has an overall responsibility to provide direction and guidance for the management, operation, and administration of First Nation of Na-Cho Nyäk Dun in a manner consistent with direction provided by the General Assembly (Na-Cho Nyäk Dun 2009). These terms are outlined in the *First Nation of Na-Cho Nyäk Dun Constitution* (Na-Cho Nyäk Dun 2009). The 2023 to 2027 First Nation of Na-Cho Nyäk Dun leadership is Chief Dawna Hope, Deputy Chief Roberta Hager, and councillors Edward Brown, Helaina Moses, Geri-Lee Buyck, and Paul Profeit.

2.7.1.2 Mayo

The Village of Mayo (Mayo) is located approximately 400 km north of Whitehorse at the confluence of the Mayo and Stewart rivers within the Traditional Territory of First Nation of Na-Cho Nyäk Dun. Mayo was founded in 1903 by Alfred Mayo, an early prospector and trader. By 1920, Mayo became one of the main

[5] Registered population refers to population data gathered by Statistics Canada through censuses. Chance recognizes First Nation citizenship data may differ from registered population data gathered by Statistics Canada. Registered population data available through Statistics Canada is limited to censuses completed.

points for shipping silver ore from Keno Hill to Whitehorse (Village of Mayo n.d.). In 1950, an all-weather road was built connecting Mayo to the Klondike Highway. In 2021, Mayo's total population was 188 people (Government of Canada 2022).

The Mayo municipal government is composed of one mayor and four councillors, each of whom are elected for a 4-year term (Village of Mayo, n.d.). In 2021, the industries with the largest proportion of the workforce were public administration, construction, and educational services (Government of Canada 2022).

Mayo is served by the Mayo Health Centre, an ambulatory healthcare facility for primary care that offers immunization clinics, prenatal classes, postnatal care, school health clinics, 24/7 emergency services, and ambulance services that respond to highway accidents (Government of Yukon 2018). Emergency response services, specifically ambulance and firefighting services, are run by local community volunteers (Village of Mayo, n.d.).

The local J.V. Clark School runs from Kindergarten to Grade 12. Mayo also has a Yukon University campus that offers in-person and distance learning certificates, diplomas, degrees, vocational and upgrading programs and courses (Government of Yukon 2022).

2.7.2 Project Notification

Chance initiated consultation and engagement with First Nation of Na-Cho Nyäk Dun on December 1, 2017. Chance sent a letter (**Appendix 2-A First Nation of Na-Cho Nyäk Dun and Residents of Mayo Consultation and Engagement Records**) that proposed the development of an engagement and consultation plan and next steps to develop a partnership with First Nation of Na-Cho Nyäk Dun.

2.7.3 Consultation and Engagement Planning

Chance developed a *First Nation of Na-Cho Nyäk Dun and Chance Oil and Gas Limited Engagement and Consultation Plan* (**Appendix 2-A**) outlining a proposed consultation and engagement approach with First Nation of Na-Cho Nyäk Dun. This plan included information on communication pathways, meeting processes, engagement documentation, and adaptive management. Chance shared the plan with First Nation of Na-Cho Nyäk Dun on May 16, 2018 for review and comment.

Implementation of consultation and engagement activities remains ongoing.

2.7.4 Consultation and Engagement Methods

Consultation and engagement methods with First Nation of Na-Cho Nyäk Dun up to December 20, 2023 included:

- meetings (virtual and in-person);
- letters;
- correspondence via phone call, text message, and email;
- Projects handouts; and,
- Information sharing (e.g., sharing Project documents for review and comment).
- Chance will adjust consultation and engagement methods in response to feedback from First Nation of Na-Cho Nyäk Dun throughout the life of the Project.

2.7.5 Consultation and Engagement Activities

Table 2-2 outlines an overview[6] of consultation and engagement activities undertaken with First Nation of Na-Cho Nyäk Dun up to December 20, 2023.

Engagement materials such as presentations and handouts shared with First Nation of Na-Cho Nyäk Dun and residents of Mayo have been compiled in **Appendix 2-A** of this Project Proposal. Where appendices were unavailable for compilation, **Table 2-2** indicates as such with an asterisk.

[6] The overview of consultation and engagement activities include meetings and events between, as well as letters and documents shared between, Chance and First Nations.

Table 2-2. Key Consultation and Engagement Activities with First Nation of Na-Cho Nyäk Dun

Recipient or Participant	Engagement Activity	Date	Description of Chance Consultation and Engagement
First Nation of Na-Cho Nyäk Dun	Correspondence via phone call, text message, meeting, and email	Ongoing	Coordinating engagement activities and sharing Project information.
First Nation of Na-Cho Nyäk Dun Residents of Mayo	Community Open House Event	17-Jun-2014	Held an open house in Mayo at First Nation of Na-Cho Nyäk Dun's Multi-Purpose Room in their government building (**Appendix 2-A**)*.
First Nation of Na-Cho Nyäk Dun	Document sharing for records	13-Sep-2016	Provided a 2-page document outlining key elements of the Project (**Appendix 2-A**).
First Nation of Na-Cho Nyäk Dun	Letter	15-Sep-2016	Provided a draft of their Yukon First Nation Engagement and Consultation Strategy (**Appendix 2-A**)*.
First Nation of Na-Cho Nyäk Dun	Letter	01-Dec-2017	Requested to co-develop a communications and engagement plan (**Appendix 2-A**).
Chance First Nation of Na-Cho Nyäk Dun	Meeting	22-Jan-2018	Requested an update of engagement planning mandates (**Appendix 2-A**)*[7].
Chance First Nation of Na-Cho Nyäk Dun	Meeting	09-Apr-2018	Discussed relationship building and opportunities to share views on the relationship and the proposed communications and engagement plan (**Appendix 2-A**)*.
First Nation of Na-Cho Nyäk Dun	Phone Call	01-May-2018	Provided the Chief an update on the progress made to the communications and engagement plan being developed with all potentially affected First Nations (**Appendix 2-A**)*.
First Nation of Na-Cho Nyäk Dun	Meeting	05-May-2018	Discussed the Project (**Appendix 2-A**)*.
First Nation of Na-Cho Nyäk Dun	Letter	07-May-2018	Notified that Chance would be submitting a tenure extension request of the Exploration Permits 0012-117 (**Appendix 2-A**)*.
First Nation of Na-Cho Nyäk Dun	Document sharing for review and comment	16-May-2018	Shared the First Nation of Na-Cho Nyäk Dun and Chance Oil and Gas Limited Engagement and Communication Plan (Draft Version 1) (**Appendix 2-A**).

[7] Engagement records between December 20, 2023 to February 2024 were not available at the time this chapter was written.

Recipient or Participant	Engagement Activity	Date	Description of Chance Consultation and Engagement
Chance First Nation of Na-Cho Nyäk Dun	Meeting	03-Aug-2018	Discussed the First Nation of Na-Cho Nyäk Dun and Chance Oil and Gas Limited Engagement and Communication Plan (Version 1) (**Appendix 2-A**)*.
First Nation of Na-Cho Nyäk Dun	Document sharing for review and comment	05-Aug-2018	Shared the First Nation of Na-Cho Nyäk Dun and Chance Oil and Gas Limited Engagement and Communication Plan (Version 2) (**Appendix 2-A**)*.
Chance First Nation of Na-Cho Nyäk Dun	Meeting	06-Nov-2018	Discussed the implementation of the First Nation of Na-Cho Nyäk Dun and Chance Oil and Gas Limited Engagement and Communication Plan (Version 2) (**Appendix 2-A**).
Chance First Nation of Na-Cho Nyäk Dun Vuntut Gwitchin First Nation Gwich'in Tribal Council Government of Yukon	Meeting	01-Feb-2019	Discussed the First Nation engagement plans, the *Vuntut Gwitchin First Nation Oil and Gas Engagement Policy*, and the *Draft Project Description* (Version 1) (**Appendix 2-A**).
Chance First Nation of Na-Cho Nyäk Dun	Meeting	10-Jun-2019	Discussed the Draft *Project Description* (Version 1) and annual reporting requirements for the Government of Yukon (**Appendix 2-A**).
First Nation of Na-Cho Nyäk Dun	Document sharing for records	14-Jun-2019	Provided information on summer field work participation opportunities (**Appendix 2-A**).
First Nation of Na-Cho Nyäk Dun	Document sharing for records	14-Jun-2019	Shared a notice letter with First Nation of Na-Cho Nyäk Dun stating Environmental Dynamics Inc. (EDI) will be conducting fish and environmental studies scheduled from July 1 to July 10, 2019 pending authorization from the Fisheries and Oceans Canada (DFO) license (**Appendix 2-A**).
First Nation of Na-Cho Nyäk Dun	Document sharing for records	24-Jul-2020	Shared the Project Proposal (Version 1) (**Appendix 2-A**).
First Nation of Na-Cho Nyäk Dun	Document sharing for records	24-Jul-2020	Shared the Emergency Spill Response Plan (**Appendix 2-A**).
Chance First Nation of Na-Cho Nyäk Dun	Meeting	05-May-2021	Presented the *Draft Project Description* (Version 1). Provided information on baseline studies. Discussed consultation and engagement next steps (**Appendix 2-A**).

Recipient or Participant	Engagement Activity	Date	Description of Chance Consultation and Engagement
First Nation of Na-Cho Nyäk Dun	Document sharing for review and comment	18-May-2021	Shared the Chance Eagle Plains Exploration Project: Baseline Information on Terrain Permafrost and Suitability Maps (**Appendix 2-A**).
First Nation of Na-Cho Nyäk Dun	Document sharing for review and comment	02-Aug-2021	Shared the Draft 2021 Annual Report on the Implementation First Nation of Na-Cho Nyäk Dun and Chance Oil and Gas Engagement and Communication Plan (**Appendix 2-A**).
Chance First Nation of Na-Cho Nyäk Dun Vuntut Gwitchin First Nation Gwich'in Tribal Council Government of Yukon	Document sharing for review and comment	20-Jan-2022	Provided the updated Heritage Resource Impact Assessment: Eagle Plains Exploration Project 2022 Interim Report (22-22ASR) (**Appendix 2-A**).
Chance First Nation of Na-Cho Nyäk Dun Vuntut Gwitchin First Nation Gwich'in Tribal Council Government of Yukon	Document sharing for review and comment	29-Nov-2022	Provided the updated Heritage Resource Impact Assessment: Eagle Plains Exploration Project 2022 Interim Report (22-22ASR) (**Appendix 2-A**).
Chance Leadership and technical advisors from: Gwich'in Tribal Council First Nation of Na-Cho Nyäk Dun Vuntut Gwitchin First Nation	Meeting	26-Jan-2023	Hosted an in-person meeting in Vancouver, BC to re-establish collaborative working relationships, discuss consultation and engagement preferences, and to provide a Project update (**Appendix 2-A**).
Chance First Nation of Na-Cho Nyäk Dun Vuntut Gwitchin First Nation Gwich'in Tribal Council Government of Yukon	Document sharing for review and comment	15-Mar-2023	Provided the updated Heritage Resource Impact Assessment: Eagle Plains Exploration Project 2022 Interim Report (22-22ASR) (**Appendix 2-A**).
First Nation of Na-Cho Nyäk Dun	Document sharing for review and comment	13-Jul-2023	Shared the *Draft Project Description* (Version 1) (**Appendix 2-A**).
Chance Advisor acting on behalf of:	Meeting	03-Aug-2023	Discussed the *Draft Project Description* (Version 2) (**Appendix 2-A**).

Recipient or Participant	Engagement Activity	Date	Description of Chance Consultation and Engagement
First Nation of Na-Cho Nyäk Dun and Tr'ondëk Hwëch'in			Proposed consultation and engagement activities with First Nation of Na-Cho Nyäk Dun.
First Nation of Na-Cho Nyäk Dun	Document sharing for records	05-Sep-2023	Shared the Wildlife Baseline Studies (**Appendix 2-A**).
First Nation of Na-Cho Nyäk Dun	Document sharing for records	05-Sep-2023	Shared the *Linear Feature Study* (**Appendix 2-A**).
First Nation of Na-Cho Nyäk Dun	Document sharing for records	05-Sep-2023	Shared the 2D and 3D Seismic Plain Language Summary (**Appendix 2-A**).
First Nation of Na-Cho Nyäk Dun	Document sharing for records	05-Sep-2023	Shared the Draft Project Overview Video (**Appendix 2-A**).
Chance Gwich'in Tribal Council Advisor acting on behalf of: First Nation of Na-Cho Nyäk Dun and Tr'ondëk Hwëch'in Vuntut Gwitchin First Nation YESAB Government of Yukon	Meeting	13-Oct-2023	Discussed the Project's assessment process, capacity funding, and possible efficiencies through a coordinated approach (e.g., sharing consultants to support potentially affected First Nations' review of the Project Proposal) (**Appendix 2-A**).
Chance First Nation of Na-Cho Nyäk Dun Technical Advisor	Email	14-Nov-2023	Informed Chance that First Nation of Na-Cho Nyäk Dun is not interested in being consulted about the Project, but that they would like to receive Project-related information (**Appendix 2-A**).
Chance First Nation of Na-Cho Nyäk Dun	Letter	17-Nov-2023	Sent a letter to Chief and Council requesting confirmation that First Nation of Na-Cho Nyäk Dun are not interested in being consulted about the Project in response to email received on November 14, 2023 (**Appendix 2-A**).
First Nation of Na-Cho Nyäk Dun Gwich'in Tribal Council Porcupine Caribou Management Board Tr'ondëk Hwëch'in Vuntut Gwitchin First Nation Government of Yukon	Meeting	20-Dec-2023	Discussed completed environmental baseline studies; potential effects on fish and wildlife and potential mitigation measures for fish and wildlife; potential PCH effects and potential mitigations; and the *Linear Features Study* and North Yukon Land Use Planning conformity (**Appendix 2-A**).

Recipient or Participant	Engagement Activity	Date	Description of Chance Consultation and Engagement
Chance EDI TWC			
* = Appendix was not available at the time this section was drafted.			

2.7.6 Agreements

Chance and First Nation of Na-Cho Nyäk Dun signed a Benefits Agreement to support First Nation of Na-Cho Nyäk Dun's involvement in Chance's drilling and seismic programs and activities in Eagle Plains between 2011 and 2014. The agreement ended upon completion of the well maintenance activities in 2014.

Chance and First Nation of Na-Cho Nyäk Dun have not discussed any formal agreement for the Project to date. Though outside the scope of this Project, First Nation of Na-Cho Nyäk Dun, Vuntut Gwitchin First Nation, Government of Yukon, and Chance signed a Benefits Agreement on October 25, 2023 for their Well Maintenance Project.

2.7.7 Records Management

Appendix 2-A includes a record of contact documenting all consultation and engagement activities including emails, phone calls, text messages, letters, meetings, and events between Chance and First Nation of Na-Cho Nyäk Dun up to December 20, 2023.

2.7.8 Consultation and Engagement Feedback (Effects, Issues, and Interests)

Chance sought to obtain feedback from potentially affected First Nations and residents of communities through Project engagement activities. **Table 2-3** presents effects, issues, and interests shared by First Nation of Na-Cho Nyäk Dun with Chance up to December 20, 2023.

Table 2-3. First Nation of Na-Cho Nyäk Dun Key Issues and Consultation and Engagement Feedback

Interaction Type	Participant / Respondent	Date	Comment / Issue	Chance Response at the Time of Engagement	Chance Response at Project Proposal Submission
Project Design					
Meeting	First Nation of Na-Cho Nyäk Dun	09-Apr-2018	Requested information regarding resource extraction planning and timelines.	No response was provided at the time.	The purpose of the Eagle Plains Exploration Project is to determine the quantity and quality of oil and natural gas resources in Eagle Plains. Chance will then compare that data with existing data from other locations to assess the viability of future development activity. If sufficient oil and/or natural gas resources are discovered, Chance may propose to conduct a future extraction project. Any future extraction project would undergo an environmental assessment. There is currently no extraction plan.
Meeting	First Nation of Na-Cho Nyäk Dun	09-Apr-2018	Asked if the Project included a refinery.	No response was provided at the time.	The Project does not include a refinery.
Meeting	First Nation of Na-Cho Nyäk Dun	09-Apr-2018	Expressed concerns about oil spills.	Chance acknowledged and recorded the comment.	Chance will develop and implement procedures to prevent the inadvertent release of oil to the ground or waterways. Additionally, Chance will develop an Emergency Spill and Response Plan and implement an Environmental Protection Plan which will include details about environmental monitoring and internal compliance with the spill prevention and response measures.
Meeting	First Nation of Na-Cho Nyäk Dun	09-Apr- 2018	Requested information regarding the quantity of oil and natural gas resources in Eagle Plains in comparison to quantities in other known oil and gas regions.	Chance acknowledged and recorded the comment.	The purpose of the Eagle Plains Exploration Project is to determine the quantity and quality of oil and natural gas resources in Eagle Plains. Chance will then compare that data with existing data from other locations to assess the viability of future development activity. If sufficient oil and/or natural gas resources are discovered, Chance may propose to conduct a future extraction project. Any future extraction project would

					undergo an environmental assessment. There is currently no extraction plan.
Consultation and Engagement					
Community Open House Event	First Nation of Na-Cho Nyäk Dun	16-Jun-2014	Stated they were not pleased there was no question-and-answer period after the event and expressed disapproval for the Project.	Chance acknowledged and recorded the comment.	Chance is committed to providing question-and-answer periods at future Project-related community events with First Nation of Na-Cho Nyäk Dun Citizens.
Meeting	First Nation of Na-Cho Nyäk Dun	26-Jan-2023	Commented that the Project development process has been lengthy.	Chance acknowledged and recorded the comment. Chance responded that consultation and engagement is a priority, which requires time, and expressed the desire for open dialogue and feedback. Chance is committed to addressing potentially affected First Nations' concerns.	Chance is committed to building positive and open relationships with all potentially affected First Nations. Chance will consult and engage with potentially affected First Nations in a respectful manner and in accordance with First Nation protocols and preferences, and *YESAA* requirements.
Meeting	First Nation of Na-Cho Nyäk Dun	26-Jan-2023	Expressed a desire for positive relationships between northern Indigenous communities and Chance. Noted the importance of moving forward and for northern First Nations to work together and support one another.	Chance acknowledged and recorded the comment. Chance committed to understanding how each potentially affected First Nation wishes to be engaged and the best ways to share information.	Chance is committed to building positive and open relationships with all potentially affected First Nations. Chance will consult and engage with potentially affected First Nations in a respectful manner and in accordance with First Nation protocols and preferences, and *YESAA* requirements. Chance created and supported opportunities for all potentially affected First Nations to meet with YESAB, Government of Yukon, and Government of Canada to discuss the Project's assessment process and related capacity funding

Interaction Type	Participant / Respondent	Date	Comment / Issue	Chance Response at the Time of Engagement	Chance Response at Project Proposal Submission
					opportunities for potentially affected First Nations.
Wildlife and Wildlife Habitat					
Meeting	First Nation of Na-Cho Nyäk Dun	03-Aug-2023	Raised concerns on seismic-program related effects on predator-prey relationships.	Chance acknowledged and recorded the comment.	Chance undertook a study on linear features to evaluate potential Project-related effects on the movement of people and animals, as well as the dispersal of plants within a given landscape. Historical linear features are largely naturally revegetated, and more recent linear features are showing good signs of naturally recovering to their original state. Usage of these disturbed areas does not seem to indicate any predatory advantage nor human presence. Two localized conditions limit greater ease of travel. Vegetation is fairly open and has limited effect on impeding movement. Ground cover, thick peat, and graminoid tussocks limit movement (see **Section 9**). Chance utilizes design components, such as using meandering seismic lines, which aim to minimize visual disturbance and make it more difficult for predators and hunters to travel along the lines. Chance is open to further dialogue to best address this issue. Chance shared the *Linear Features Study* for review and records (See **Appendix 8-B**).
Heritage Resources					
Meeting	First Nation of Na-Cho Nyäk Dun	05-May-2021	Stated the importance of receiving contributions from First Nation of Na-Cho Nyäk Dun on heritage resources. Requested to review the heritage studies.	Chance acknowledged and recorded the comment. Chance responded that First Nation of Na-Cho Nyäk Dun's feedback and input on heritage studies is critical. Chance shared 4 heritage studies with First Nation of	Chance continues to be committed to sharing future heritage studies with the First Nation of Na-Cho Nyäk Dun for their review and comment. Chance will work with potentially affected First Nations to support their involvement in future heritage resources studies.

Interaction Type	Participant / Respondent	Date	Comment / Issue	Chance Response at the Time of Engagement	Chance Response at Project Proposal Submission
				Na-Cho Nyäk Dun in May 2021, January 2022, December 2022, and March 2023 for their review and records.	See **Section 10** for information on Project-related effects to and mitigation measures for heritage resources.

2.7.9 Ongoing Consultation and Engagement

While a consultant for First Nation of Na-Cho Nyäk Dun has indicated that the First Nation does not currently wish to be consulted about the Project prior to proposal submission, Chance will continue to share Project information and updates. However, at any time, if the First Nation of Na-Cho Nyäk Dun wishes to be actively consulted and engaged with, Chance will adapt the Program to reflect such changes. Planned and possible ongoing consultation and engagement activities include (and are not limited to):

- Project communications (e.g., updates regarding schedule, permitting, monitoring activities, incorporation of Indigenous Knowledge to Project plans, capacity funding);
- meetings to discuss Project-related effects, issues, input, and interests;
- opportunities to review and provide comment on Project plans and materials; and,
- opportunities to develop Project-related mitigation measures.

2.8 CONSULTATION AND ENGAGEMENT WITH GWICH'IN TRIBAL COUNCIL, AND RESIDENTS OF INUVIK, FORT MCPHERSON, TSIIGEHTCHIC, AND AKLAVIK

Section 2.8 outlines consultation and engagement activities with Gwich'in Tribal Council and residents of Inuvik, Fort McPherson, Tsiigehtchic, and Aklavik. Information on Project notification, consultation and engagement planning, methods, activities, and agreements, issues, interests, input, and feedback shared through consultation and engagement activities are described in **Sections 2.8.1- 2.8.10**.

2.8.1 Community Profiles

The following subsections describe Gwich'in Tribal Council and the communities of Inuvik, Fort McPherson, Tsiigehtchic, and Aklavik.

2.8.1.1 Gwich'in Tribal Council

> "Ek'italtsi' means Image, or Identity, and sets the tone of who we are as a people, who we see ourselves as, and how we conduct ourselves outwardly. It is a celebration and pride in our history, traditions, and culture." (Gwich'in Tribal Council 2021)

Gwich'in peoples have lived in Alaska, NWT, and the Yukon since time immemorial (Gwich'in Tribal Council, n.d.-a). There are more than 9,000 Gwich'in peoples who live in Alaska, NWT, and the Yukon today (Gwich'in Council International, n.d.). There are 3,500 Gwich'in Participants located in the communities of Aklavik, Inuvik, Teetł'it Zheh (Fort McPherson), and Tsiigehtchic (Gwich'in Tribal Council, n.d.-e).

The Gwich'in Tribal Council represents the interests of Gwich'in peoples in Aklavik, Inuvik, Teetł'it Zheh, and Tsiigehtchic (Gwich'in Tribal Council, n.d.-a; n.d.-h). Its government is comprised of a Grand Chief, the Tetł'it Gwich'in Council, the Ehdiitat Gwich'in Council, and the Nihtat Gwich'in Council.

The current government is composed of: Grand Chief Ken Kyikavichik, Director Grace Martin of the Tetł'it Gwich'in Council, Director Danny Green of the Ehdiitat Gwich'in Council, Director Michael Greenland of the

Ehdiitat Gwich'in Council, Vice President Chris Smith of the Nihtat Gwich'in Council, and Director Kelly McLeod of the Nihtat Gwich'in Council (Gwich'in Tribal Council, n.d.-c).

The Gwich'in Tribal Council owns the Gwich'in Settlement Corporation and the Gwich'in Development Corporation (Gwich'in Tribal Council, n.d.-a). The Gwich'in Settlement Corporation manages capital transfers that Gwich'in Tribal Council receives from the Government of Canada (Gwich'in Tribal Council, n.d.-b). The Gwich'in Development Corporation creates economic opportunities for the Gwich'in Tribal Council by acquiring investments and business partnerships (Gwich'in Development Corporation, n.d.).

Figure 2-4 outlines the governance structure of Gwich'in Tribal Council.

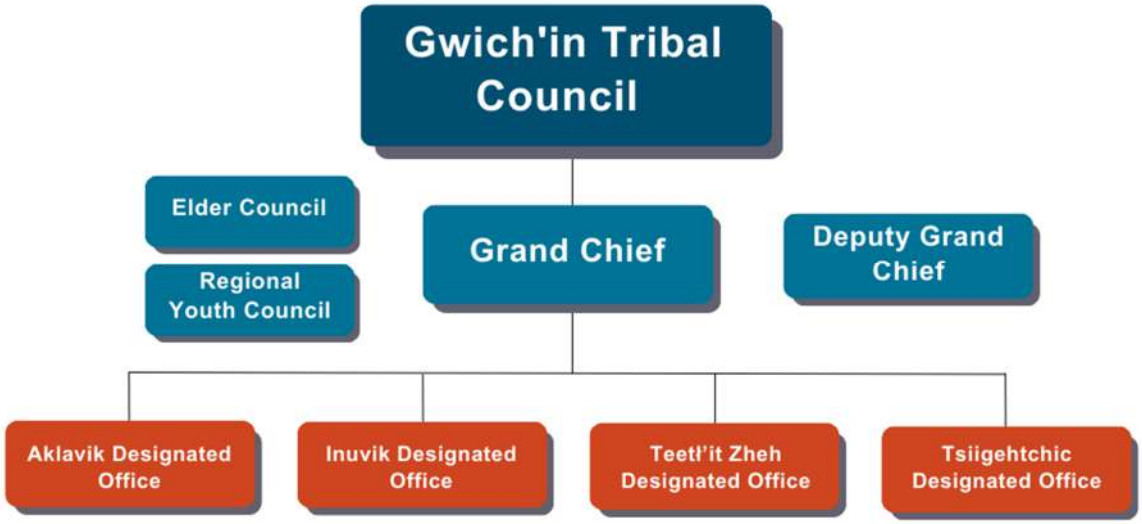

Figure 2-4. Gwich'in Governance Structure

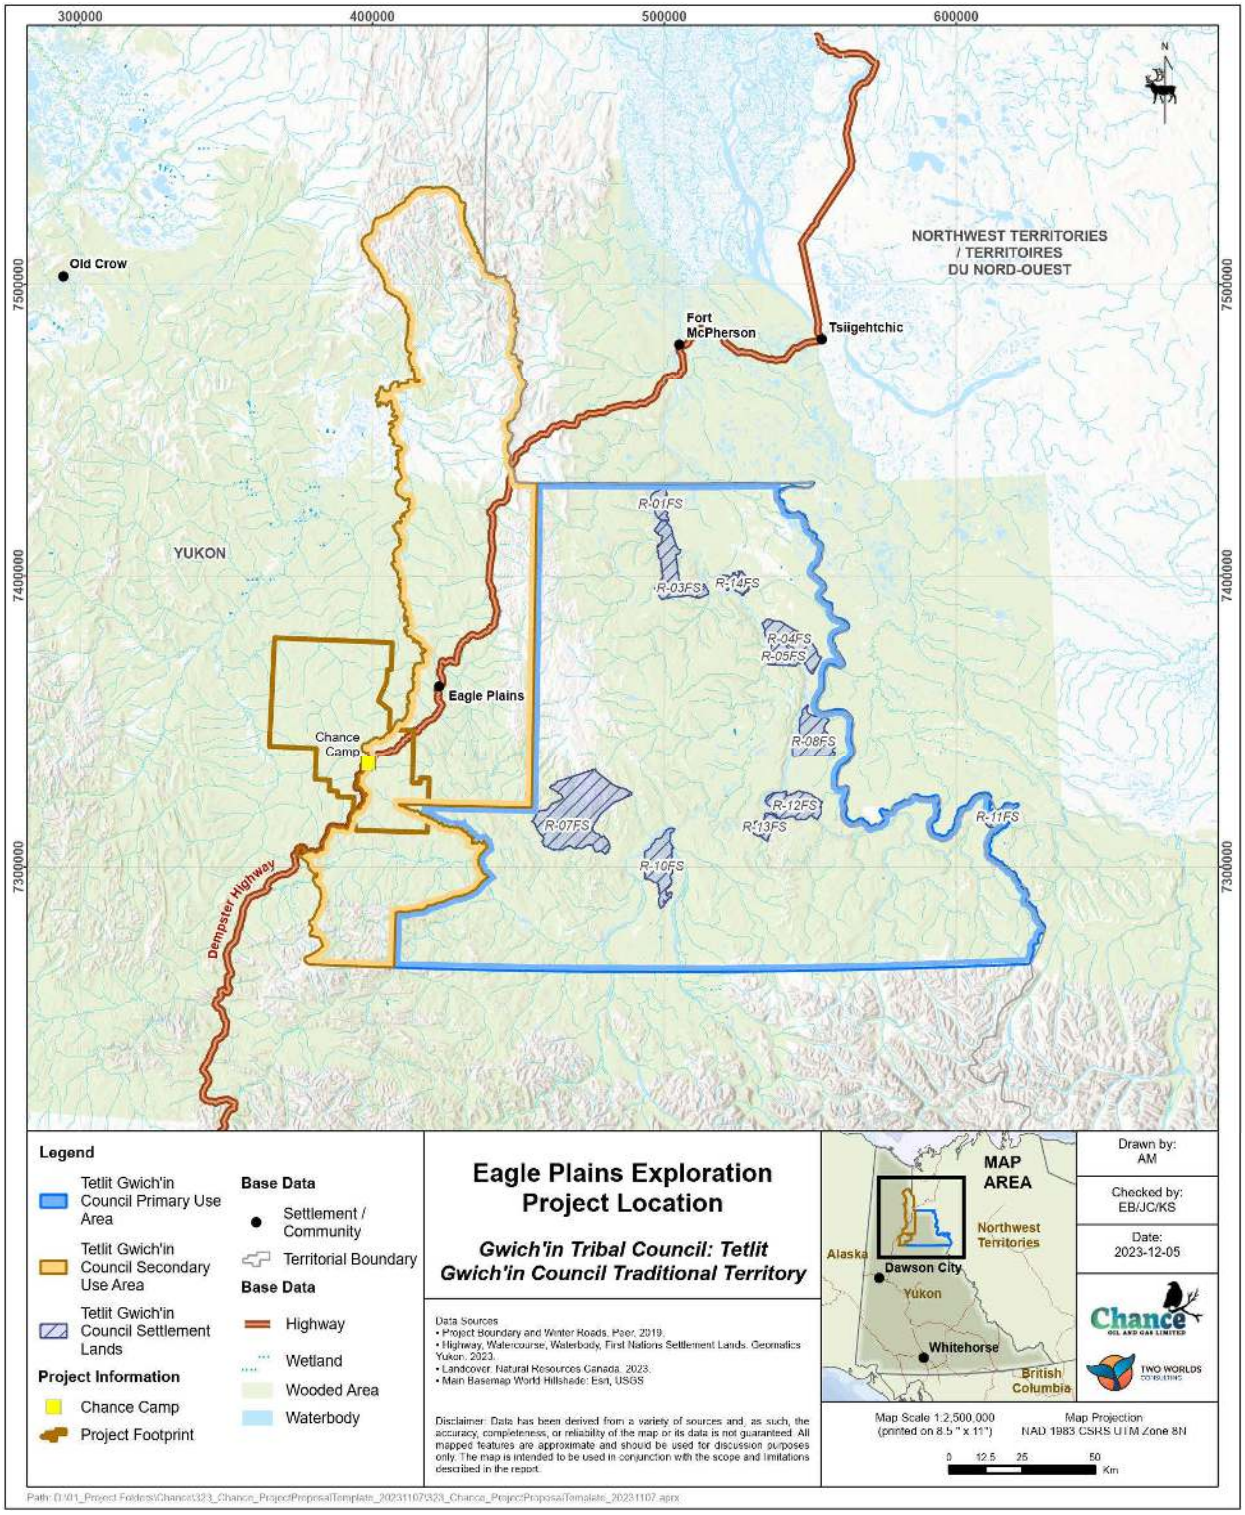
Grand Chief Ken Kyikavichik serves as the Lead Negotiator of the Regional Gwich'in Collaborative, responsible for negotiating the Gwich'in Collaborative Government on behalf of the communities of Aklavik, Teetł'it Zheh (Fort McPherson), and Tsiigehtchic (Gwich'in Tribal Council, n.d.-d).

Gwich'in Tribal Council's main office is in Inuvik, NWT (Gwich'in Tribal Council, n.d.-a). Other Gwich'in Tribal Council offices are in Yellowknife and Edmonton (Gwich'in Tribal Council, n.d.-a).

Gwich'in Tribal Council's Department of Cultural Heritage notes that the Gwich'in language Dinjii Zhu' Ginjik is one of the most endangered Indigenous languages in Canada (Gwich'in Tribal Council Department of Cultural Heritage, n.d.). There are approximately 270 Dinjii Zhu' Ginjik first language speakers as of 2016 (Clark 2020).

The Gwich'in Traditional Territory stretches from Alaska, through the Yukon, to the Mackenzie Valley in the NWT (Gwich'in Tribal Council, n.d.-e). Treaty 11 was signed in July 1921 by the Gwich'in of Tsiigehtchic (previously Arctic Red River) and Teetł'it Zheh (Gwich'in Tribal Council, n.d.-a). **Map 2-3** illustrates current Gwich'in land management and use areas (Gwich'in Tribal Council, n.d.-g). These also include their secondary and primary use areas to the west and south.

In 1992, the Government of Canada, the Government of the Northwest Territories, and Gwich'in Tribal Council signed the *Gwich'in Comprehensive Land Claim Agreement*—also referred to as the Gwich'in Agreement (Government of Canada and Gwich'in Tribal Council 1992; Gwich'in Tribal Council, n.d.-f). This modern treaty agreement includes information on ownership of land, economic benefits, land and environmental management, hunting and fishing, and self-governance.



Map 2-3: Gwich'in Tribal Council: Tetlit Gwitch'in Council Traditional Territory

2.8.2 Inuvik

The Town of Inuvik (Inuvik) is located 200 km north of the Arctic Circle, on the traditional lands of the Inuvialuit, Gwich'in, and Métis people (Town of Inuvik 2021a). It was established in the 1950s to support the federal government's relocation of the community of Aklavik, which was experiencing severe flooding damage. Today, Aklavik remains in its original location (Government of the Northwest Territories n.d.). Inuvik achieved municipal incorporation in 1979 and is currently the third largest community in the NWT (Municipal and Community Affairs n.d.b). It is the administrative centre for the Beaufort Delta (Town of Inuvik 2021b), and currently has a population of 3,137 residents (Statistics Canada 2023c).

Inuvik is governed by a council composed of one mayor and eight councillors. The current town council, in office from 2021 to 2024, is comprised of: Mayor Clarence Wood, Deputy Mayor Natasha Kulikowski, and Councillors Whitney Alexis, Ned Day, Tony Devlin, Grant Gowans, Jesse Harder, Alana Mero, and Kurt Wainman (Town of Inuvik 2021d).

Key economic sectors in Inuvik include transportation, construction, petroleum exploration, and public administration. Additionally, there is growth potential in the tourism industry (Town of Inuvik 2021b). Most residents are employed in territorial and local governments and Indigenous government offices (Town of Inuvik 2021a). Residents continue to engage in traditional economies through hunting, trapping, and fishing, which are an integral part of the community's culture and economy.

Inuvik has the only hospital facility in the Beaufort Delta region, offering diverse medical services, including emergency care, acute treatment, diagnostic imaging, laboratory testing, long-term care, rehabilitation, health education and promotion, obstetrical care, operating room services, and an on-site pharmacy. Specialists from Yellowknife and Edmonton offer services on a rotational basis, such as dermatology, ear, nose and throat care, gynecology, internal medicine, neurology, ophthalmology, orthopaedics, pediatrics, psychiatry, and surgery as needed (Town of Inuvik 2021e). The Inuvik hospital serves Fort McPherson, Aklavik, Tsiigehtchic, Tuktoyaktuk, Paulatuk, Sach's Harbour, and Ulukhaktok (Practice NWT n.d.).

There is one elementary school (Kindergarten to Grade 7), the East Three Elementary School, and one secondary school (Grade 7-12), the East Three Secondary School (Beaufort Delta Divisional Education Council 2021). Aurora College, a post-secondary institution, provides services including academic upgrading, diploma and degree options, technical training, apprenticeships, and continuing education opportunities (Town of Inuvik 2021c).

Please refer to **Section 11** for more socio-economic information regarding Inuvik.

2.8.2.1 Fort McPherson

The traditional name of the Hamlet of Fort McPherson (the Hamlet) is Teet'lit Zheh, which means "place at the head waters". The name's origin lies in its location on the east bank of Teetł'it Gwinjik in the Beaufort Delta (Spectacular Northwest Territories 2019). Incorporated as a municipality in 1986, the Hamlet was established in 1849 when a Hudson's Bay Company trading post was set up 4 miles from the current community (Hamlet of Fort McPherson 2010a). As of 2021, the Hamlet had a population of 647 (Statistics Canada 2023a).

The Hamlet's municipal government is composed of one mayor and eight councillors, each elected for a 3-year term. The most recent election was held in December 2023 (GNWT 2023), which resulted in the election of: Mayor Rebecca Blake and Councillors Stanley Snowshoe, George Nerysoo, Joyce Blake, Sierra

Daley, Kyla Ross, Ruby McDonald, Priscilla Itsi, and Lawrence Firth (Municipal and Community Affairs n.d.a).

Fort McPherson's economy is highly dependent on employment and economic opportunities from the Government of Northwest Territories. The Hamlet, the Designated Gwich'in Organization, and the school are the main employers (Hamlet of Fort McPherson 2010b). The Hamlet also relies on the construction and transportation industries, along with local businesses such as the Fort McPherson Tent and Canvas Factory (Hamlet of Fort McPherson 2010a; 2010b).

The William Firth Sriigwindaih Zheh Health Centre provides general healthcare services via nursing staff and visiting practitioners that provide primary care to Fort McPherson residents (Health and Social Services Authority n.d.b; Practice NWT n.d.). The nearest hospital is in Inuvik, 186 km away and accessible by road (Town of Inuvik 2021e).

Fort McPherson has one school (Kindergarten to Grade 12), the Chief Julius School, operated by the Beaufort Delta Education Council (Beaufort Delta District Education Council 2021).

Please refer to **Section 11** for more socio-economic information regarding Fort McPherson.

2.8.2.2 Tsiigehtchic

Tsiigehtchic, formerly known as Arctic Red River, is a charter community in the Beaufort Delta, which overlooks the confluence of the Mackenzie River and Arctic Red River (Ecology North 2010). Tsiigehtchic translates to "at the mouth of the iron river" in the Gwich'in language, which may be in reference to an iron mineral deposit found in the soil further up the Arctic Red River (Gwich'in Tribal Council, n.d.-a). In 2021, the population of Tsiigehtchic was 138 (Statistics Canada 2023d).

The municipal government is composed of the Gwichya Gwich'in Council's elected Chief and Council, one Chief and three councillors elected by the First Nation's election code, and two additional councillors elected through the NWT's *Local Election Act* (Ingrid Kritsch 2012).

The economy of Tsiigehtchic is primarily comprised of public administration, education services, utilities, administrative support, waste management and remediation services (Statistics Canada 2023d).

The Tsiighehtchic Health Centre provides general primary care services via nursing staff and visiting practitioners (Health and Social Services Authority n.d.c; Practice NWT n.d.). The nearest hospital is in Inuvik, 129 km away by road (Town of Inuvik 2021e).

Tsiigehtchic has one school (Kindergarten to Grade 12), the Chief Paul Nidtichis School, operated by the Beaufort Delta Education Council (Beaufort Delta District Education Council 2023a).

Please refer to **Section 11** for more socio-economic information regarding Tsiigehtchic.

2.8.2.3 Aklavik

Aklavik translates to "barren ground grizzly place" (Spectacular Northwest Territories 2023) and is located on the Peel channel of the Mackenzie River Delta (Gwich'in Tribal Council 2016). According to the 2021 Census, Aklavik's population is 536 (Statistics Canada 2023b).

Aklavik's economy is primarily supported by public administration, educational services, construction, retail, and health care and social assistance (Statistics Canada 2023b).

The Susie Husky Health and Social Services Centre, Aklavik's health centre, provides general health services via nursing staff and visiting practitioners that provide primary care to residents ((Health and Social Services Authority n.d.a; Practice NWT n.d.). The nearest hospital is in Inuvik, only accessible by plane (Town of Inuvik 2021e).

Aklavik has one school (Kindergarten to Grade 12), the Moose Kerr School, operated by the Beaufort Delta Education Council (Beaufort Delta District Education Council 2023b).

Please refer to **Section 11** for more socio-economic information regarding Aklavik.

2.8.3 Project Notification

Chance initiated engagement with Gwich'in Tribal Council on December 1, 2017. Chance sent a letter (**Appendix 2-B Gwich'in Tribal Council and Residents of Inuvik, Fort McPherson, Tsiigehtchic, and Aklavik Consultation and Engagement Records**) to Gwich'in Tribal Council about the *Gwich'in Partners and Chance Oil and Gas Limited Communications and Consultation Plan* and next steps to develop a partnership with Gwich'in Tribal Council.

Chance initiated consultation and engagement with residents of Aklavik, Inuvik, Tsiigehtchic, and Fort McPherson at community open house events in August 2019.

2.8.4 Consultation and Engagement Planning

Chance developed the *Gwich'in Partners and Chance Oil and Gas Limited Communications and Consultation Plan* (**Appendix 2-B**) outlining a proposed engagement approach with Gwich'in Tribal Council. The plan included information on communication pathways, meeting process, engagement documentation, and adaptive management.

Chance shared the *Gwich'in Partners and Chance Oil and Gas Limited Communications and Consultation Plan* with Gwich'in Tribal Council for review and comment and received a signed copy from Gwich'in Tribal Council on January 9, 2019. The implementation of this proposed engagement approach remains ongoing.

2.8.5 Consultation and Engagement Methods

Engagement methods with Gwich'in Tribal Council up to December 20, 2023, included

- meetings (virtual and in-person);
- teleconference;
- letters;
- handouts;
- correspondence via phone call, text message, and email;
- community open house event; and,
- information sharing (e.g., sharing Project documents for review and comment).
- Chance will adjust consultation and engagement methods in response to feedback from Gwich'in Tribal Council throughout the life of the Project.

Consultation and engagement methods with residents of Inuvik, Fort McPherson, Tsiigehtchic, and Aklavik up to December 20, 2023 included community open house events and handouts.

2.8.6 Consultation and Engagement Activities

Table 2-4 outlines engagement activities undertaken with Gwich'in Tribal Council and residents of Inuvik, Fort McPherson, Tsiigehtchic, and Aklavik up to December 20, 2023.

Engagement materials such as presentations and handouts shared with Gwich'in Tribal Council and residents of Inuvik, Fort McPherson, Tsiigehtchic, and Aklavik have been compiled in **Appendix 2-B** of this Project Proposal. Where appendices were unavailable for compilation, **Table 2-4** indicates as such with an asterisk.

Table 2-4. Consultation and Engagement Activities with Gwich'in Tribal Council and Residents of Inuvik, Fort McPherson, Tsiigehtchic, and Aklavik

Recipient or Participant	Engagement Activity	Date	Description of Chance Consultation and Engagement
Gwich'in Tribal Council	Correspondence via phone call, text message, meeting, and email	Ongoing	Coordinating engagement activities and sharing Project information.
Gwich'in Tribal Council	Letter	22-Jan-2015	Received a letter stating that Gwich'in Tribal Council reviewed Chance's Project application against their heritage databases and listed their concerns. These concerns are listed in Table 4: Consultation and Engagement Feedback from Gwich'in Tribal Council and Residents of Inuvik, Fort McPherson, Tsiigehtchic, and Aklavik (**Appendix 2-B**).
Gwich'in Tribal Council	Letter	26-Sep-2016	Sent a letter to Gwich'in Tribal Council discussing the Project, future meetings, partnership opportunities for First Nations, information regarding the Judicial Review, and the protection of the PCH (**Appendix 2-B**).
Gwich'in Tribal Council Tetł'it Gwich'in Council	Letter	01-Dec-2017	Provided Tetł'it Gwich'in Council with information on the Gwich'in Partners and Chance Oil and Gas Limited Communications and Consultation Plan that Chance wished to develop in partnership with Tetł'it Gwich'in Council (**Appendix 2-B**).
Chance Gwich'in Tribal Council	Meeting	22-Jan-2018	Discussed relationship-building, future Project consultation engagement activities, and the communications and engagement plan Chance hoped to develop (**Appendix 2-B**)*.
Chance Gwich'in Tribal Council Tetł'it Gwich'in Council	Meeting	24-Apr-2018	Discussed Project information, roles and responsibilities, relationship building, and the communications and engagement plan that Chance hoped to develop (**Appendix 2-B**).
Gwich'in Tribal Council	Document sharing for review and comment	07-May-2018	Shared the Draft Gwich'in Partners and Chance Oil and Gas Limited Communications and Consultation Plan (**Appendix 2-B**).
Chance Tetł'it Gwich'in Council	Document sharing for records	08-May-2018	Shared a map related to the extension of their exploration permits (**Appendix 2-B**). An updated map showing exploration permit areas is in **Section 1** of the Project Proposal.
Gwich'in Tribal Council Tetł'it Gwich'in Council	Letter	08-May-2018	Notified Gwich'in Tribal Council and Tetł'it Gwich'in Council about extending exploration tenure permits (**Appendix 2-B**).

Recipient or Participant	Engagement Activity	Date	Description of Chance Consultation and Engagement
Gwich'in Tribal Council	Meeting	29-May-2018	Discussed the Gwich'in Partners and Chance Oil and Gas Limited Communications and Consultation Plan and draft meeting minutes from April 24, 2018 (**Appendix 2-B**)*.
Gwich'in Tribal Council	Meeting	27-Jul-2018	Discussed and reviewed the Gwich'in Partners and Chance Oil and Gas Limited Communications and Consultation Plan (**Appendix 2-B**)*.
Gwich'in Tribal Council	Meeting	31-Jul-2018	Discussed and reviewed the Gwich'in Partners and Chance Oil and Gas Limited Communications and Consultation Plan (**Appendix 2-B**)*.
Gwich'in Tribal Council	Meeting	01-Aug-2018	Discussed final revisions to the *Gwich'in Partners and Chance Oil and Gas Limited Communications and Consultation Plan* and agreed that the plan did not need to be signed (**Appendix 2-B**)*.
Gwich'in Tribal Council	Document sharing for records	01-Aug-2018	Final Gwich'in Partners and Chance Oil and Gas Limited Communications and Consultation Plan (**Appendix 2-B**)*.
Gwich'in Tribal Council	Document sharing for review and comment	15-Oct-2018	Shared the Draft *Terms of Reference (TOR)* (Version 1) (**Appendix 2-B**)*.
Chance Gwich'in Tribal Council	Meeting	17-Oct-2018	Discussed implementation of the Gwich'in Partners and Chance Oil and Gas Limited Communications and Consultation Plan. Identified the members of the Communications and Consultation Management Committee (**Appendix 2-B**)*.
Gwich'in Tribal Council	Document sharing for review and comment	24-Oct-2018	Shared the Draft *Confidentiality Agreement* (**Appendix 2-B**).
Gwich'in Tribal Council	Document sharing for records	13-Nov-2018	Shared a map of Chance's permitted Project footprint (**Appendix 2-B**)*.
Gwich'in Tribal Council	Document sharing for records	13-Nov-2018	Shared the Gwich'in Partners and Chance Oil and Gas Limited Communications and Consultation Plan (**Appendix 2-B**)*.
Gwich'in Tribal Council	Document sharing for records	13-Nov-2018	Shared the Draft *TOR* (**Appendix 2-B**)*.
Gwich'in Tribal Council	Meeting	15-Nov-2018	Discussed implementation of the *Gwich'in Partners and Chance Oil and Gas Limited Communications and Consultation Plan* and next steps between Gwich'in Tribal Council and Chance (**Appendix 2-B**)*.

Recipient or Participant	Engagement Activity	Date	Description of Chance Consultation and Engagement
Gwich'in Tribal Council	Document sharing for records	21-Nov-2018	Shared the Draft *TOR* (Version 2) (**Appendix 2-B**)*.
Chance Gwich'in Tribal Council	Meeting	14-Dec-2018	Discussed the Gwich'in Partners and Chance Oil and Gas Limited Communications and Consultation Plan, draft Cooperation Agreement, TOR, and Confidentiality Agreement. (**Appendix 2-B**)*.
Chance	Document sharing for records	09-Jan-2019	Shared a signed Gwich'in Partners and Chance Oil and Gas Limited Communications and Consultation Plan with Chance for their records (**Appendix 2-B**).
Chance First Nation of Na-Cho Nyäk Dun Vuntut Gwitchin First Nation Gwich'in Tribal Council Government of Yukon	Meeting	01-Feb-2019	Discussed the First Nation Consultation Plans, the *Vuntut Gwitchin First Nation Oil and Gas Engagement Policy*, and the *Draft Project Description* (Version 1) (**Appendix 2-B**).
Gwich'in Tribal Council	Letter	26-Mar-2019	Notified Gwich'in Tribal Council of Chance's tenure extension request (**Appendix 2-B**).
Gwich'in Tribal Council	Fieldwork (Email)	21-May-2019	Provided Tetł'it Gwich'in Council a formal notification regarding fieldwork to extract rock samples out of Eagle Plains Basin planned between July 10 and 24, 2019. (**Appendix 2-B**).
Gwich'in Tribal Council	Document sharing for records	05-Jun-2019	Shared the Draft *Project Description* (**Appendix 2-B**).
Gwich'in Tribal Council	Meeting	07-Jun-2019	Met with Gwich'in Tribal Council leadership to discuss the Project, land tenure extension requests to the Government of Yukon, and consultation and engagement (**Appendix 2-B**).
Nihtat Gwich'in Council	Document sharing for records	10-Jun-2019	Shared a Draft *Project Description* with Nihtat Gwich'in Council (**Appendix 2-B**).
Gwich'in Tribal Council	Document sharing for records	14-Jun-2019	Shared the Eagle Plains Environmental Studies 2018 (**Appendix 2-B**).
Gwich'in Tribal Council	Letter	14-Jun-2019	Shared a notice letter with Gwich'in Tribal Council stating EDI will be conducting fish and environmental studies scheduled from July 1 to July 10, 2019, pending authorization from the Fisheries and Oceans Canada (DFO) license (**Appendix 2-B**).

Recipient or Participant	Engagement Activity	Date	Description of Chance Consultation and Engagement
Gwich'in Tribal Council	Fieldwork (Email)	17-Jun-2019	Invited Gwich'in Tribal Council to send 2 Gwich'in Participants to join the planned environmental monitoring programs for the summer (**Appendix 2-B**).
Chance Gwich'in Tribal Council Residents of Tsiigehtchic	Community Open House Event	19-Aug-2019	Chance met with Gwich'in Participants and residents of Tsiigehtchic to provide a Project update. The open house included a presentation and catered dinner. In total, 14 Gwich'in Participants and residents of Tsiigehtchic attended the open house (**Appendix 2-B**)*.
Chance Gwich'in Tribal Council Residents of Inuvik	Community Open House Event	20-Aug-2019	Met with Gwich'in Participants and residents of Inuvik to provide a Project update. The open house included a presentation and catered dinner. In total, 8 Gwich'in Participants and residents of Aklavik attended the open house (**Appendix 2-B**)*.
Chance Gwich'in Tribal Council Residents of Aklavik	Community Open House Event	21-Aug-2019	Met with Gwich'in Participants and residents of Aklavik to provide a Project update. The open house included a presentation and catered dinner. In total, 10 Gwich'in Participants and residents of Aklavik attended the open house (**Appendix 2-B**)*.
Chance Gwich'in Tribal Council Residents of Fort McPherson	Community Open House Event	22-Aug-2019	Met with Gwich'in Participants and residents of Fort McPherson to provide a Project update. The open house included a presentation and catered dinner (**Appendix 2-B**)*.
Chance	Letter	18-Sep-2019	Shared a letter with Chance that Gwich'in Social and Cultural Institute drafted for YESAB (**Appendix 2-B**).
Gwich'in Tribal Council	Meeting	22-Nov-2019	Met with Gwich'in Tribal Council about the Project (**Appendix 2-B**)*.
Gwich'in Tribal Council	Document sharing for records	22-Nov-2019	Shared the Project Summary (**Appendix 2-B**).
Gwich'in Tribal Council	Letter	22-May-2020	Shared a letter titled Initiation of Engagement for Eagle Plain Well Maintenance Project (**Appendix 2-B**).
Gwich'in Tribal Council	Document sharing for records	18-Jun-2020	Shared the Draft *Project Description* (Version 1) (**Appendix 2-B**).
Chance	Document sharing for records	08-Jul-2020	Shared the memo titled *Response to Gwich'in Tribal Council Comments* on the Eagle Plain Well Maintenance Project. These comments from Gwich'in Tribal Council were originally received by Chance on June 18, 2020 (**Appendix 2-B**).

Recipient or Participant	Engagement Activity	Date	Description of Chance Consultation and Engagement
Gwich'in Tribal Council	Document sharing for review and comment	13-Jul-2020	Draft 2020 Annual Report on the Implementation of Gwich'in Partners and Chance Oil and Gas Communications and Consultation Plan (**Appendix 2-B**).
Chance Gwich'in Tribal Council	Meeting	22-Jul-2020	Discussed Project design changes resulting from consultation and engagement feedback and refinement of the *Draft Project Description* (Version 1) (**Appendix 2-B**).
Chance	Document sharing for review and comment	30-Jul-2020	Provided comments on the Draft 2020 Annual Report on the Implementation of Gwich'in Partners and Chance Oil and Gas Communications and Consultation Plan (**Appendix 2-B**).
Chance	Document sharing for review and comment	02-Sep-2020	Provided comments on the Draft *Project Description* (Version 1) with Chance (**Appendix 2-B**)*.
Chance Gwich'in Tribal Council	Virtual meeting	16-Nov-2020	Met with recently elected Gwich'in Tribal Council leadership to introduce the company and Project (**Appendix 2-B**).
Chance Gwich'in Tribal Council	Meeting	03-Jun-2021	Presented on the Draft *Project Description* (Version 1) and provided updates regarding baseline information gathered by its consultants. Chance and Gwich'in Tribal Council discussed consultation and engagement next steps. Gwich'in Tribal Council brought up concerns regarding the Mix Bury Cover (MBC) sumps, water usage, depths of disposal wells, and the presence of aquifers in those areas (**Appendix 2-B**).
Gwich'in Tribal Council	Document sharing for review and comment	17-Jun-2021	Shared the Draft *Project Description* (Version 1) (**Appendix 2-B**).
Gwich'in Tribal Council	Document sharing for records	30-Jun-2021	Shared the *Suitability Map and Surficial Geology* document from Palmer (**Appendix 2-B**).
Gwich'in Tribal Council	Document sharing for review and revisions	16-Jul-2021	Shared the Draft 2021 Annual Report: Implementation of the Gwich'in Partners and Chance Oil and Gas Communications and Consultation Plan (**Appendix 2-B**).
Gwich'in Tribal Council	Document sharing for records	23-Jul-2021	Shared the ground photos of Devon Sump (**Appendix 2-B**).
Chance	Letter	30-Aug-2021	Shared feedback on the *2021 Annual Engagement Plan* (**Appendix 2-B**).

Recipient or Participant	Engagement Activity	Date	Description of Chance Consultation and Engagement
Gwich'in Tribal Council	Document sharing for review and signature	10-Sep-2021	Shared the updated draft *2021 Annual Engagement Plan* and outlined changes made based on Gwich'in Tribal Council's feedback. Gwich'in Tribal Council requested a change to the Gwich'in Tribal Council signatory name. Chance provided an updated copy for signing (**Appendix 2-B**).
First Nation of Na-Cho Nyäk Dun Vuntut Gwitchin First Nation Gwich'in Tribal Council Tr'ondëk Hwëch'in	Document sharing for records	17-Dec-2021	Shared the letter to the Government of Yukon, Land Tenure Extension Request for Exploration (Permits 0008-0017, 0019 and 0020 ("Permits") (**Appendix 2-B**).
Chance First Nation of Na-Cho Nyäk Dun Vuntut Gwitchin First Nation Gwich'in Tribal Council Government of Yukon	Document sharing for review and comment	20-Jan-2022	Provided an updated Heritage Resource Impact Assessment: Eagle Plains Exploration Project 2022 Interim Report (22-22ASR) (**Appendix 2-B**).
Gwich'in Tribal Council	Letter	07-Jun-2022	Stated Chance would like to propose initial terms of reference for ongoing engagement and for the collaborative process necessary to conclude a *Cooperation Agreement* (**Appendix 2-B**).
Chance First Nation of Na-Cho Nyäk Dun Vuntut Gwitchin First Nation Gwich'in Tribal Council Government of Yukon	Document sharing for review and comment	29-Nov-2022	Provided an updated Heritage Resource Impact Assessment: Eagle Plains Exploration Project 2022 Interim Report (22-22ASR) (**Appendix 2-B**).
Chance Gwich'in Tribal Council First Nation of Na-Cho Nyäk Dun Tr'ondëk Hwëch'in Vuntut Gwitchin First Nation	Meeting	26-Jan-2023	Hosted an in-person meeting in Vancouver, BC to re-establish collaborative working relationships, discuss consultation and engagement preferences going forward, and provide a Project update (**Appendix 2-B**).
Gwich'in Tribal Council	Letter	07-Mar-2023	Sent Gwich'in Tribal Council a letter regarding a land tenure extension for Exploration Permits 0012-0017, and 0020 (**Appendix 2-B**).

Recipient or Participant	Engagement Activity	Date	Description of Chance Consultation and Engagement
Chance First Nation of Na-Cho Nyäk Dun Vuntut Gwitchin First Nation Gwich'in Tribal Council Government of Yukon	Document sharing for review and comment	15-Mar-2023	Provided an updated Heritage Resource Impact Assessment: Eagle Plains Exploration Project 2022 Interim Report (22-22ASR) (**Appendix 2-B**).
Gwich'in Tribal Council	Letter	05-Apr-2023	Notified Gwich'in Tribal Council of potential future socio-economic data collection starting June 11, 2023. Requested a meeting in Old Crow on May 15, 2023. Included a summary of the Project and a proposed schedule for engagement (**Appendix 2-B**).
Gwich'in Tribal Council	Meeting	16-May-2023	Provided a Project update (**Appendix 2-B**)*.
Gwich'in Tribal Council Residents of Inuvik	Community Open House Event	16-May-2023	Held a community open house in Inuvik at the Nihtat Gwich'in Council Board Room. Six community members attended this event and provided feedback. Chance shared Project information on posterboards and a 1-page handout. Chance provided a catered dinner and presented Project information to open house attendees. (**Appendix 2-B**).
Gwich'in Tribal Council	Meeting	17-May-2023	Hosted an in-person meeting with Grand Chief Ken Kyikavichik staff from the Gwich'in Development Corporation, and Chance and the Project team to discuss Project updates, Gwich'in Tribal Council and Gwich'in Development Corporation's consultation and engagement preferences, and to give an overview of the May 16, 2023, Open House in Inuvik (**Appendix 2-B**).
Gwich'in Tribal Council	Document sharing for review and comment	13-Jul-2023	Shared the Draft *Project Description* (Version 2) (**Appendix 2-B**).
Tetłʼit Gwich'in Council	Document sharing for review and comment	14-Jul-2023	Shared the Draft *Project Description* (Version 2) (**Appendix 2-B**).
Gwich'in Tribal Council	Virtual meeting	29-Aug-2023	Shared the re-introduced the Draft *Project Description* (Version 2) and discussed engagement (**Appendix 2-B**).
Gwich'in Tribal Council	Virtual meeting	27-Sep-2023	Re-introduced the Draft *Project Description* (Version 2) and discussed engagement. Discussed topics included: information on exploration, design changes, baseline studies, and the assessment process (**Appendix 2-B**).

Recipient or Participant	Engagement Activity	Date	Description of Chance Consultation and Engagement
Chance Potentially affected First Nations Gwich'in Tribal Council Government of Canda YESAB Government of Yukon	Meeting	13-Oct-2023	Discussed the Project's assessment process including capacity funding and possible efficiencies through a coordinated approach (e.g., sharing consultants to support potentially affected First Nations' review of the Draft *Project Description* (Version 2) (**Appendix 2-B**).
Chance EDI TWC Gwich'in Tribal Council	Meeting	01-Nov-2023	Discussed Project Proposal updates and schedule, as well as upcoming Consultation and engagement activities. Discussed how the Gwich'in Tribal Council is experiencing ongoing capacity challenges. Gwich'in Tribal Council shared concerns about cumulative effects in the Peel Watershed and cumulative effects of greenhouse gas emissions (**Appendix 2-B**).
Chance EDI TWC Gwich'in Tribal Council	Meeting	04-Dec-2023	Discussed upcoming consultation and engagement activities. Gwich'in Tribal Council expressed concerns about lack of cultural or heritage baseline data. See **Section 2.8.9** for more information on how Chance responded to this feedback (**Appendix 2-B**).
Chance Gwich'in Tribal Council Staff Gwich'in Participants Residents of Fort McPherson Residents of Tsiigehtchic Residents of Aklavik	Community Open House Event	07-Dec-2023	Held a hybrid online and in-person community open house in Fort McPherson at the Tetlit' Zheh Fort McPherson Hamlet Chamber. Twenty-Six Gwich'in Participants attended this event. Chance shared Project information through a PowerPoint presentation, a Project Overview Video, posterboards, and a 1-page handout. Chance provided a catered dinner, door prizes, and responded to questions and presented Project information to open house attendees. (**Appendix 2-B**).
First Nation of Na-Cho Nyäk Dun Gwich'in Tribal Council Porcupine Caribou Management Board Tr'ondëk Hwëch'in Vuntut Gwitchin First Nation Government of Yukon Chance EDI	Meeting	20-Dec-2023	Discussed completed environmental baseline studies; potential effects on fish and wildlife and potential mitigation measures for fish and wildlife; potential PCH effects and potential mitigations; and the *Linear Features Study* and North Yukon Land Use Planning conformity (**Appendix 2-B**).

Recipient or Participant	Engagement Activity	Date	Description of Chance Consultation and Engagement
TWC			
* = Appendix was not available at the time this section was drafted.			

2.8.7 Agreements

Chance and Gwich'in Tribal Council have not discussed any formal agreement for the Project to date.

2.8.8 Records Management

Appendix 2-B includes a record of contact documenting all consultation and engagement activities including emails, phone calls, text messages, letters, meetings, and events between Chance and Gwich'in Tribal Council up to December 20, 2023 and a record of contact documenting all consultation and engagement activities with residents of Inuvik, Fort McPherson, Tsiigehtchic, and Aklavik up to December 20, 2023 (**Appendix 2-B**).

2.8.9 Consultation and Engagement Feedback (Effects, Issues, and Interests)

Chance sought to obtain feedback from potentially affected First Nations and residents of communities through Project engagement activities. **Table 2-5** presents effects, issues, and interests shared by Gwich'in Tribal Council and residents of Inuvik, Fort McPherson, Tsiigehtchic, and Aklavik with Chance up to December 20, 2023.

Table 2-5. Gwich'in Tribal Council Consultation and Engagement Key Issues and Feedback

Interaction Type	Respondent	Date	Comment / Issue	Chance Response at the Time of Engagement	Chance Response at Project Proposal Submission
Aquatic Resources					
Community Open House Event	Gwich'in Tribal Council Gwich'in Participants Residents of Inuvik	16-May-2023	Asked if the Project considered potential effects to frogs.	Project activities are primarily in winter when frogs will be dispersed and hibernating below the soil surface. Due to primary winter activities and minimal soil disturbance, Project interactions with frogs are expected to be negligible and were not evaluated further.	Comment was addressed at the time it was shared. See **Section 8** for more information on Project-related effects on and protection measures for wildlife and wildlife habitat.
Community Open House Event	Gwich'in Tribal Council Gwich'in Participants Residents of Inuvik	16-May-2023	Asked if the Project considered potential effects to invertebrates including water insects.	Due to primary winter activities and minimal soil disturbance, Project interactions with invertebrates are expected to be negligible and were not evaluated further.	Comment was addressed at the time it was shared. See **Section 8** for more information on Project-related effects on and protection measures for wildlife and wildlife habitat.
Project Design					
Letter	Gwich'in Tribal Council	22-Jan-2015	Expressed concern for the size of the Project, the number of wells, and establishment of new all-season roads.	Chance acknowledged and recorded the comment.	Chance modified the Project design to eliminate all-season roads from the Project. Instead, Chance will utilize winter ice roads. Chance acknowledges Gwich'in Tribal Council's concerns about the number of well sites. **Section 1** describes how the well sites and design will incorporate key features to enhance efficiency, reduce waste, and minimize general effects on the surrounding environment (see **Section 1**). Chance will limit traffic on the winter access to authorized personnel. Traffic will include approximately 8 to 9 light-weight service trucks daily (for supplies

Interaction Type	Respondent	Date	Comment / Issue	Chance Response at the Time of Engagement	Chance Response at Project Proposal Submission
					and personnel), 1 to 2 water trucks, and 1 fuel truck as frequently as exploration activities dictate (see **Section 1**).
Community Open House Event	Gwich'in Tribal Council Gwich'in Participants Residents of Inuvik	16-May-2023	Asked about mercury and fire effects on well heads.	The Chance Project Team said no mercury or fire effects are expected.	Comment was addressed at the time it was shared. See **Section 1** for more information on Project design.
Community Open House Event	Gwich'in Tribal Council Gwich'in Participants Residents of Inuvik	16-May-2023	Asked Chance to clarify what dog legged means.	The Chance Project Team clarified that the term "dog legged" referred to crocked or bent. This term was used in reference to the proposed seismic activities for the Project versus more traditional grid seismic lines from the 1990s.	Chance utilizes design components, such as using meandering seismic lines, which aim to minimize visual disturbance and make it more difficult for predators and hunters to travel along the lines. Chance is open to further dialogue to best address this issue. See **Section 1** for more information on Project design.
Community Open House Event	Gwich'in Tribal Council Gwich'in Participants Residents of Inuvik	16-May-2023	Asked where Project sewage will go (e.g., river, lake, or land).	The Chance Project Team said all wastewater and sewage will be collected in tanks approved by the Canadian Standards Association and transported offsite for disposal at an approved facility in Fort McPherson.	Comment was addressed at the time it was shared. See **Section 1** for more information on Project design.
Community Open House Event	Gwich'in Tribal Council Gwich'in Participants Residents of Inuvik	16-May-2023	Asked about the end users of oil and gas products from the Project.	The Chance Project Team confirmed end users of a potential future extraction project are expected to be folks and businesses from Yukon and NWT. Confirmed any future extraction Project would undergo an environmental assessment.	If sufficient oil and/or natural gas resources are discovered, Chance may propose to conduct a future extraction project. Any future extraction project would undergo an environmental assessment. There is currently no extraction plan. Comment was addressed at the time it was shared.

Interaction Type	Respondent	Date	Comment / Issue	Chance Response at the Time of Engagement	Chance Response at Project Proposal Submission
				Confirmed this Project has no end-use product and focuses on exploration.	See **Section 1** for more information on Project design.
Community Open House Event	Gwich'in Tribal Council Gwich'in Participants Residents of Inuvik	16-May-2023	Asked how Chance collects seismic data.	The Chance Project Team confirmed seismic data are collected by technology called geophones. Added that geophones are placed in the ground and then picked up by helicopter and taken to a lab for data analysis.	Comment was addressed at the time it was shared. See **Section 1** for more information on Project design.
Community Open House Event	Gwich'in Tribal Council Gwich'in Participants Residents of Inuvik	16-May-2023	Asked if Chance is only drilling in the winter.	The Chance Project Team confirmed that Project drilling activities will occur only in the winter.	Comment was addressed at the time it was shared. See **Section 1** for more information on Project design.
Community Open House Event	Gwich'in Tribal Council Gwich'in Participants Residents of Inuvik	16-May-2023	Asked how many wells there are so far.	The Chance Project Team confirmed there are 6 existing wells in the Eagle Plains area. Added that Chance is proposing to drill up to 30 wells over a 10-year period.	Comment was addressed at the time it was shared. See **Section 1** for more information on Project design.
Community Open House Event	Gwich'in Tribal Council Gwich'in Participants Residents of Inuvik	16-May-2023	Asked how Chance reclaims well sites.	The Chance Project Team said progressive reclamation will be ongoing throughout the Project. Added that wells will be plugged and covered to support natural revegetation.	Comment was addressed at the time it was shared. See **Section 1** for more information on Project design.
Community Open House Event	Gwich'in Tribal Council Gwich'in Participants Residents of Fort McPherson	07-Dec-2023	Asked how many roads the Project will have, how deep the drilling will be, what type of drill will be used, how many wells are anticipated, if there will be fracking,	Chance acknowledged and recorded the comment. Chance responded that there will be 2 roads, the drilling will be up to 2.5 km deep, that there will be no fracking, there will be up to 30 wells, and	Comment was addressed at the time it was shared. See **Section 1** for more information on Project design.

Interaction Type	Respondent	Date	Comment / Issue	Chance Response at the Time of Engagement	Chance Response at Project Proposal Submission
	Residents of Tsiigehtchic Residents of Aklavik		and what methods will be used to extract oil and gas.	explained that the Project strives to confirm the quality and quantity of oil and gas in the Project footprint.	
Community Open House Event	Gwich'in Tribal Council Gwich'in Participants Residents of Inuvik Residents of Tsiigehtchic Residents of Aklavik	07-Dec-2023	Inquired about what the Project is going to do to get the oil from the ground.	The Chance Project Team shared that the Project only includes exploration activities. Extraction activities are not part of the Project.	Any future extraction project would undergo an environmental assessment. There is currently no extraction plan. See **Section 1** for more information on Project design.
Community Open House Event	Gwich'in Tribal Council Gwich'in Participants Residents of Inuvik Residents of Tsiigehtchic Residents of Aklavik	07-Dec-2023	Asked how many wells will be drilled.	The Chance Project Team confirmed up to 30 wells will be drilled over a 10-year period.	Comment was addressed at the time it was shared. See **Section 1** for more information on Project design.
Consultation and Engagement					
Meeting	Gwich'in Tribal Council	16-Nov-2020 26-Jan-2023	Expressed interest in further understanding Project timelines and a collaborative approach with proponents, requesting Chance to provide additional time for reviewing Project documents, with the aim to communicate effectively to Citizens.	Chance acknowledged and recorded the comment.	Chance is committed to building positive and open relationships with all potentially affected First Nations. Chance will consult and engage with potentially affected First Nations in a respectful manner and in accordance with First Nation protocols and preferences, and *YESAA* requirements.

Interaction Type	Respondent	Date	Comment / Issue	Chance Response at the Time of Engagement	Chance Response at Project Proposal Submission
Meeting	Gwich'in Tribal Council	26-Jan-2023	Expressed interest in advancing discussions around historic and current use of the land in the Project footprint and associated effects on Treaty rights and access.	Chance acknowledged and recorded the comment.	Chance is committed to building positive and open relationships with all potentially affected First Nations. Chance will consult and engage with potentially affected First Nations in a respectful manner and in accordance with First Nation protocols and preferences, and *YESAA* requirements.
Community Open House Event	Gwich'in Tribal Council Gwich'in Participants Residents of Inuvik	16-May-2023	Suggested Chance advertise future community engagement events in Inuvik at the post office, churches, and the grocery store. Asked if Chance is talking to Elders. Added that it is important to listen and follow what Elders say as they have wisdom and know what they are talking about. Noted Elders are not on Facebook. Mentioned the importance of knowing both sides of the story to the best decision is made.	Chance acknowledged and recorded the comment.	Comment was addressed at the time it was shared.
Meeting	Gwich'in Tribal Council	17-May-2023	Asked Chance to use language depicting the Project's effects on the area instead of characterizing its significance. Acknowledged the importance of providing	Chance acknowledged and recorded the comment.	Chance is committed to building positive and open relationships with all potentially affected First Nations. Chance acknowledges Gwich'in Tribal Council's comment and will focus on accurately assessing and describing

Interaction Type	Respondent	Date	Comment / Issue	Chance Response at the Time of Engagement	Chance Response at Project Proposal Submission
			the community with the appropriate context for discussing potential effects and illustrated how specific language can be misleading.		effects and communicating those to potentially affected First Nations. Chance will consult and engage with potentially affected First Nations in a respectful manner and in accordance with First Nation protocols and preferences, and *YESAA* requirements.
Meeting	Gwich'in Tribal Council	27-Sep-2023	Emphasized the need for pre-approval prior to initiating consultation and engagement activities.	Chance acknowledged and recorded the comment. Chance seeks guidance from the Gwich'in Tribal Council for leadership-specific consultation and engagement activities.	Chance is committed to building positive and open relationships with all potentially affected First Nations. Chance will consult and engage with potentially affected First Nations in a respectful manner and in accordance with First Nation protocols and preferences, and *YESAA* requirements.
Community Open House Event	Gwich'in Tribal Council Gwich'in Participants Residents of Fort McPherson Residents of Tsiigehtchic Residents of Aklavik	07-Dec-2023	Rated the Open House "OK to Very Satisfied". Stated that the Open House had a lot of good information. Stated that the event helped them learn more about Chance and the Project. Stated that the Open House had good information on Chance and the Project.	Chance acknowledged and recorded the comment.	Comment was addressed at the time it was shared.
Community Open House Event	Gwich'in Tribal Council Gwich'in Participants Residents of Fort McPherson	07-Dec-2023	Noted they were not able to share their thoughts, ideas, and knowledge during the event in a comfortable manner.	Chance acknowledged the comment and will look at finding additional opportunities for Gwich'in Participants to comfortably share their thoughts, ideas, and knowledge during future	Comment was addressed at the time it was shared.

Interaction Type	Respondent	Date	Comment / Issue	Chance Response at the Time of Engagement	Chance Response at Project Proposal Submission
	Residents of Tsiigehtchic Residents of Aklavik			community events for the Project.	
Community Open House Event	Gwich'in Tribal Council Gwich'in Participants Residents of Tsiigehtchic Residents of Aklavik Residents of Fort McPherson	07-Dec-2023	Noted that the Open House felt rushed.	Chance acknowledged the comment and shared that the Chance Project Team was informed by the venue that the room had accidentally been double booked. The planned four-hour event was compressed into two hours. Future Project-related events will be longer to avoid attendees from feeling rushed.	Comment was addressed at the time it was shared.
Community Open House Event	Gwich'in Tribal Council Gwich'in Participants Residents of Fort McPherson Residents of Tsiigehtchic Residents of Aklavik	07-Dec-2023	Stated that when seeing data, it is good to see real time photos of a site, such as ground drill holes to understand the information.	Chance acknowledged the comment and will make photos of the drill holes available to Gwich'in Participants, if the Project is approved.	Comment was addressed at the time it was shared.
Community Open House Event	Gwich'in Tribal Council Gwich'in Participants Residents of Fort McPherson Residents of Tsiigehtchic Residents of Aklavik	07-Dec-2023	Suggested having a "coffee house" platform at the end of the event to enable one-on-one discussions.	Chance acknowledged the comment and will implement opportunities for more one-on-one discussions at the end of future community events for the Project.	Comment was addressed at the time it was shared.

Interaction Type	Respondent	Date	Comment / Issue	Chance Response at the Time of Engagement	Chance Response at Project Proposal Submission
Community Health and Well-being					
Community Open House Event	Gwich'in Tribal Council Gwich'in Participants Residents of Inuvik	16-May-2023	Asked about potential Project-related effects to Inuvik and mentioned increased community investments could influence their decision-making around extending their existing work contract in Inuvik.	The Chance Project Team confirmed they hired Two Worlds Consulting to assess potential Project-related effects to communities. Added that this assessment is still underway and will be described in the Project Proposal.	Comment was addressed at the time it was shared. See **Section 11** for more information on Project-related effects on and mitigation measures for community health and well-being.
Community Open House Event	Gwich'in Tribal Council Gwich'in Participants Residents of Inuvik	16-May-2023	Noted Inuvik needs more community amenities such as Tim Hortons.	Chance acknowledged and recorded the comment.	Comment was addressed at the time it was shared. See **Section 11** for more information on Project-related effects on and mitigation measures for community health and well-being.
Community Open House Event	Gwich'in Tribal Council Gwich'in Participants Residents of Inuvik	16-May-2023	Shared difficulty access fresh produce in the spring after the ice road closes.	Chance acknowledged and recorded the comment.	Comment was addressed at the time it was shared. See **Section 11** for more information on Project-related effects on and mitigation measures for community health and well-being.
Birds					
Document Sharing: Memorandum in Response to Gwich'in Tribal Council Comments	Gwich'in Tribal Council	08-Jul-2020	Requested Chance minimize disturbance to soils and vegetation to protect bird and riparian habitat.	Chance acknowledged and recorded the comment. Chance shared that winter exploration will reduce negative effects on riparian areas. The construction and use of winter roads will minimize effects on surface vegetation.	Project-related effects on birds are described in **Section 8** of the Project Proposal. Mitigation measures are expected to address potential effects on water resources and fish. Residual effects on these values are expected to be negligible. See **Sections 5** and **6** of the Project Proposal for more details.

Interaction Type	Respondent	Date	Comment / Issue	Chance Response at the Time of Engagement	Chance Response at Project Proposal Submission
				Chance shared that winter roads follow the height of land avoiding riparian areas and water bodies. All activities occur away from riparian areas and there are no stream crossings associated with the winter roads.	See **Section 11** for more information on Project-related effects on and mitigation measures for community health and well-being.
Community Open House Event	Gwich'in Tribal Council Gwich'in Participants Residents of Inuvik	16-May-2023	Noted Project activities are not when birds are there, but chickadees may be there.	Chance acknowledged and recorded the comment and that there may be some overwintering birds in the Regional Study Area.	Comment was addressed at the time it was shared. See **Section 11** for more information on Project-related effects on and mitigation measures for community health and well-being.
Vegetation					
Document Sharing: Memorandum in Response to Gwich'in Tribal Council Comments	Gwich'in Tribal Council	08-Jul-2020	Requested Chance to avoid unnecessary degradation of the soil and destruction of wildlife habitat.	Chance acknowledged and recorded the comment. Chance shared the Project design (e.g., re-establishing winter roads and work during winter) was intended to minimize and/or eliminate potential effects on values such as soil, permafrost, vegetation, riparian areas, and wildlife habitat.	Chance acknowledges Gwich'in Tribal Council's concerns about soil and wildlife habitat protection. Chance intends to minimize and/or eliminate potential effects on values such as soil, permafrost, vegetation, riparian areas, and wildlife habitat. Chance stated that the construction and use of winter roads will minimize effects on surface vegetation and permafrost. It anticipates no negative effects on vegetation or permafrost. The winter road construction is not anticipated to affect terrain stability. It will follow the height of land and does not require grading or clearing of surface soils. Snow build up (10 cm) will be utilized to support equipment. Chance created a constraints map to identify sensitive or high-quality environmental and heritage values where

Interaction Type	Respondent	Date	Comment / Issue	Chance Response at the Time of Engagement	Chance Response at Project Proposal Submission
					Project work should be avoided or minimized. See **Section 7** for more information on Project-related effects on and mitigation measures for vegetation.
Document Sharing: Memorandum in Response to Gwich'in Tribal Council Comments	Gwich'in Tribal Council	08-Jul-2020	Expressed concern about the winter road and its effect on water bodies, wetlands, permafrost/terrain stability and the local ecology. Recommended Chance explore other access methods.	Chance acknowledged and recorded the comment. Chance shared that winter exploration will reduce negative effects on riparian areas. The construction and use of winter roads will minimize effects on surface vegetation and permafrost. It anticipates no negative effects on vegetation or permafrost. The winter road construction is not anticipated to affect terrain stability. It will follow the height of land and does not require grading or clearing of surface soils. Snow build up (10 cm) will be utilized to support equipment.	This issue is addressed in **Section 7** of the Project Proposal. Chance acknowledges this issue as a concern and will limit traffic on the winter access to authorized personnel. Traffic will include approximately 8 to 9 light-weight service trucks daily (for supplies and personnel), 1 to 2 water trucks, and 1 fuel truck as frequently as exploration activities dictate. See **Section 1** for more information. Chanced shared that winter roads follow the height of land avoiding riparian areas and water bodies. All activities occur away from riparian areas and there are no stream crossings associated with the winter roads.
Meeting	Gwich'in Tribal Council	22-Jul-2020	Requested additional information on Project clearing activities and reclamation plans.	Chance acknowledged and recorded the request for additional information. Chance provided an explanation of mitigation practices used to reduce effects on wildlife habitat such as the use of narrow (10 metres (m) wide) winter roads. Chance also indicated that it will maintain vegetation aside to preserve the root mass.	Chance recognizes the concern surrounding closure activities and reclamation. Chance is committed to following all applicable legislation and policies, including undertaking reclamation activities after Project exploration activities have been completed. Monitoring programs and follow-up monitoring will be in place. Follow-up meetings will occur to demonstrate work completed. Chance is required to set money aside for reclamation.

Interaction Type	Respondent	Date	Comment / Issue	Chance Response at the Time of Engagement	Chance Response at Project Proposal Submission
				Winter road access will be restricted to prevent additional degradation. Each well site will be roughly 1 hectare.	For more information on clearing activities and reclamation plans, see **Section 1** of the Project Proposal.
Community Open House Event	Gwich'in Tribal Council Gwich'in Participants Residents of Inuvik	16-May-2023	Asked if there are any berries in the Project footprint.	The Chance Project Team acknowledged there are berries in the Project footprint.	Comment was addressed at the time it was shared. See **Section 7** for more information on Project-related effects on and mitigation measures for community vegetation.
Community Open House Event	Gwich'in Tribal Council Gwich'in Participants Residents of Inuvik	16-May-2023	Asked what is the difference between old growth forests and new forests.	The Chance Project Team confirmed that old growth forests are considered areas with trees over 100 years old and newer forests have trees less than 100 years old.	Comment was addressed at the time it was shared. See **Section 7** for more information on Project-related effects on and mitigation measures for community vegetation.
Water Resources					
Letter Document Sharing: Memorandum in Response to Gwich'in Tribal Council Comments	Gwich'in Tribal Council	22-Jan-2015 08-Jul-2020 03-Jun-2021 26-Jan-2023	Concerns over contamination of water resources Expressed concern about temporary and permanent Project roads, and how these roads may affect water and fish in the area. Expressed concerns over water usage, depths of disposal wells, MBC sumps, and the presence of aquifers in those areas.	Chance acknowledged and recorded the comment. Chance shared the *Surface Water Quality and Hydrology Baseline* report with Gwich'in Tribal Council for their records. Chance stated that all well sites are located at least 100 m from any water bodies. Chance will use existing access and withdrawal sites to minimize the risk of erosion and sedimentation.	Chance shared the *Fish and Fish Habitat Studies* baseline report with Gwich'in Tribal Council. Chance shared the Project design (e.g., re-establishing winter roads and work during winter) was intended to minimize and/or eliminate potential effects on values such as soil, permafrost, vegetation, riparian areas, and wildlife habitat. Chance shared that winter exploration will reduce negative effects on riparian areas. Chance shared that winter roads follow the height of land avoiding riparian areas and water bodies. All activities occur away from riparian areas and there are no stream crossings associated with the winter roads. Mitigation measures are expected to address potential effects on

Interaction Type	Respondent	Date	Comment / Issue	Chance Response at the Time of Engagement	Chance Response at Project Proposal Submission
					water resources and fish. Residual effects on these values are expected to be negligible. See **Sections 5** and **6** of the Project Proposal for more details. Chance created a constraints map to identify sensitive or high-quality environmental and heritage values where Project work should be avoided or minimized. See **Section 3** for more information.
Document Sharing: Memorandum in Response to Gwich'in Tribal Council Comments	Gwich'in Tribal Council	08-Jul-2020	Inquired about the specifics of fluids for pressure and wellbore tests, raising concerns about spills and groundwater effects. Asked for risk assessments for each well based on fluid type and urged the provision of a spill response plan. Emphasized the need for personnel training in spill response and reporting, with an insistence on immediate reporting to the Government of Yukon and potentially affected First Nations for any spills.	Chance to list the fluids and materials necessary. Chance committed to developing plans to mitigate potential effects. Personnel trained in spill response will be onsite for the duration of the Project. In addition to spill response and cleanup, the spill response plan will include details on reporting requirements.	More information about the type of materials used for the flow tests is available in **Section 2.3.2** of the Project Proposal. Chance will establish and enforce procedures to prevent unintended fluid release into the environment. Furthermore, an Emergency Spill and Response Plan and an Environmental Protection Plan will be devised, encompassing specifics on environmental monitoring and internal adherence to spill prevention and response measures. Chance will develop and implement procedures to prevent the inadvertent release of oil to the ground or waterways.
Community Open House Event	Gwich'in Tribal Council Gwich'in Participants Residents of Inuvik	16-May-2023	Asked if water is monitored for residue.	The Chance Project Team said that water quality will be characterized for the effects assessment.	Comment was addressed at the time it was shared. See **Section 5** for more information on Project-related effects on and mitigation measures for water resources.

Interaction Type	Respondent	Date	Comment / Issue	Chance Response at the Time of Engagement	Chance Response at Project Proposal Submission
Meeting	Gwich'in Tribal Council	17-May-2023	Asked for additional information on the water source, its use for camp operations, and its role in drilling activities.	Chance acknowledged and recorded the comment.	This issue is addressed in **Sections 1 and 5** of the Project Proposal documents. Water for the drill rig, winter road construction, and camp operation will primarily be obtained from existing withdrawal points on the Eagle River, with alternative sources located on the Ogilvie River and Whitestone River (see **Section 5**). The allocation of water usage will be determined by licensed allowances.
Community Open House Event	Gwich'in Tribal Council Gwich'in Participants Residents of Fort McPherson Residents of Tsiigehtchic Residents of Aklavik	07-Dec-2023	Asked if any water quality studies had been conducted in the Project footprint. Asked if there had been any water quality studies conducted in the Peel River.	Chance acknowledged and recorded the comment. Chance provided an overview of the water studies conducted. It explained that heavy metals (hydrocarbons) had been identified. Chance confirmed that there have been water quality studies in the upper reaches of the Peel River.	Chance shared baseline studies with Gwich'in Tribal Council. Chance had a surface water quality and hydrology baseline report developed to inform background characteristics of surface water within the Regional Study Area. This report will guide any anticipated or intended water resource requirements. See the **Section 5** for mapping of riparian constraints within the Project footprint. See **Section 5** for more information on water quality studies in the Peel River. See **Section 5** for more information on Project-related effects on and mitigation measures for water resources.
Community Open House Event	Gwich'in Tribal Council Gwich'in Participants Residents of Fort McPherson Residents of Tsiigehtchic	07-Dec-2023	Asked how far back water baselines studies go.	The Chance Project Team conducted water fieldwork studies in 2019, 2020, and 2022. Added that additional publicly available data comes from the 1980s and 2000s.	Comment was addressed at the time it was shared..

Interaction Type	Respondent	Date	Comment / Issue	Chance Response at the Time of Engagement	Chance Response at Project Proposal Submission
	Residents of Aklavik				
Wildlife and Wildlife Habitat					
Letter Document Sharing: Memorandum in Response to Gwich'in Tribal Council Comments	Gwich'in Tribal Council	22-Jan-2015 08-Jul-2020 16-Nov-2020 22-Jul-2020	Expressed concern for Project effects on wolverines, fur-bearing animals, bald eagles, and wildlife habitat.	Chance acknowledged and recorded the comment. Chance invited the Gwich'in Tribal Council to send a wildlife monitor on-site during construction and operation activities	Chance created a constraints map to identify sensitive or high-quality environmental and heritage values where Project work should be avoided or minimized. See **Section 8** for more information. See **Section 8** for more information on Project-related effects on and mitigation measures for wildlife and wildlife habitat.
Document Sharing: Memorandum in Response to Gwich'in Tribal Council Comments	Gwich'in Tribal Council	08-Jul-2020	Expressed concern about the land use-related disturbances such as noise, smell, and light and requested Chance identify mitigation measures to reduce/avoid these disturbances. Expressed concern about human wildlife conflicts. Recommended Chance train Project personnel in best practices.	Chance acknowledged and recorded the comment. Chance to reduce disturbances such as noise, smell, and light. Winter conditions help to minimize risk to wildlife and the camp is constructed to minimize attractants. Food waste to be stored in secure areas not accessible to wildlife. Chance stated that incinerators would be present at the camp to burn organic material and reduce wildlife attractants	See **Section 8** for more information regarding Project design mitigation measures to reduce human land use related disturbances and effects on wildlife and wildlife.
Community Open House Event	Gwich'in Tribal Council Gwich'in Participants Residents of Inuvik	16-May-2023	Asked if the Project researched how to avoid high-quality moose habitat.	The Chance Project Team confirmed that moose habitat had been studied. Added that potential Project-related effects to moose habitat, and mitigation measures to address those effects, would	Comment was addressed at the time it was shared. See **Section 8** for more information on Project-related effects on and mitigation measures for wildlife and wildlife habitat.

Interaction Type	Respondent	Date	Comment / Issue	Chance Response at the Time of Engagement	Chance Response at Project Proposal Submission
				be described in the Project Proposal.	
Community Open House Event	Gwich'in Tribal Council Gwich'in Participants Residents of Inuvik	16-May-2023	Suggested Chance monitor wildlife after any damages to permafrost.	The Chance Project Team acknowledged the comment and confirmed there would be ongoing wildlife monitoring throughout the Project.	Comment was addressed at the time it was shared. See **Section 8** for more information on Project-related effects on and mitigation measures for wildlife and wildlife habitat.
Community Open House Event	Gwich'in Tribal Council Gwich'in Participants Residents of Inuvik	16-May-2023	Noted that the Project footprint is not good for grizzlies and asked about protection measures for black bears.	Due to primary winter activities and minimal soil disturbance, Project interactions with black bears are expected to be negligible. The Chance Project Team said the Project will avoid active den sites if any are identified.	Comment was addressed at the time it was shared. See **Section 8** for more information on Project-related effects on and mitigation measures for wildlife and wildlife habitat.
Community Open House Event	Gwich'in Tribal Council Gwich'in Participants Residents of Fort McPherson Residents of Tsiigehtchic Residents of Aklavik	07-Dec-2023	Stated that most Elders oppose industrial development within the Traditional Territory because of effects to caribou. Noted that the caribou travel through the Project footprint. Explained that there is a big concern from the PCMB around development effects to caribou. Added that Elders always say that "you can't eat money". Stated that Elders may be against the Project because they know when development starts in an area the caribou leave and don't	The Chance Project Team confirmed a lot of information had been received from the PCMB to inform Porcupine Caribou Herd studies for the Project. Added that the PCMB provided Chance/EDI with collared data and that Chance shared Project information and wildlife studies with the PCMB technical committee per the PCMB's direction. The Chance Project Team shared that Chance met with the PCMB on December 1st to discuss the Project and conducted a technical working group meeting with the (Porcupine Caribou Management Board PCMB) on the Porcupine Caribou Herd on	Comment was addressed at the time it was shared. See **Section 8** for more information on Project-related effects on and mitigation measures for wildlife and wildlife habitat.

Interaction Type	Respondent	Date	Comment / Issue	Chance Response at the Time of Engagement	Chance Response at Project Proposal Submission
			go back to that area. Added that caribou previously migrated through that area, which makes it a big concern for the users of the PCH Suggested that Chance have a meeting with caribou user groups.	December 20th. Chance acknowledged that industrial development could affect the environment, wildlife, and people. Chance noted that they are responsible to mitigate potential Project-related adverse effects on the environment, wildlife, and people.	
Porcupine Caribou Herd					
Letter Document Sharing: Memorandum in Response to Gwich'in Tribal Council Comments Meeting	Gwich'in Tribal Council	22-Jan-2015 08-Jul-2020 22-Jul-2020 26-Jan-2023	Expressed concerns regarding effects on caribou and the PCH specifically. Stated that caribou is a key issue. Suggested employing a wildlife monitor during Project activities to safeguard uninterrupted PCH migration. Requested more information on wildlife deterrents and techniques. Recommended that the Tetłʼit Gwichʼin Renewable Resources Council be consulted.	Chance acknowledged and recorded the comment. Chance to invite Gwich'in Tribal Council to send a wildlife monitor during construction and operation phases of the Project.	Chance conducted additional wildlife baseline studies, including studying the PCH, in 2018/19 and updated these studies in 2022/23. Chance shared the Wildlife Baseline Studies report with Gwich'in Tribal Council for their records. Chance created a constraints map to identify sensitive or high-quality environmental and heritage values where Project work should be avoided or minimized. See **Section 9** for more information. Chance acknowledges and considers concerns regarding the PCH. See **Section 9** for more information on Project-related effects on and mitigation measures for the PCH and land and resource use.
Community Open House Event	Gwich'in Tribal Council Gwich'in Participants	16-May-2023	Suggested Chance monitor where caribou are standing, as they are always moving.	The Chance Project Team shared they have been working with PCH collar data from the Porcupine Caribou Technical Committee to better	Comment was addressed at the time it was shared.

Interaction Type	Respondent	Date	Comment / Issue	Chance Response at the Time of Engagement	Chance Response at Project Proposal Submission
	Residents of Inuvik		Noted that PCH will stick around for a two-week period.	understand potential Project-related effects to the PCH.	See **Section 9** for more information on Project-related effects on and mitigation measures for the PCH.
Community Open House Event	Gwich'in Tribal Council Gwich'in Participants Residents of Inuvik	16-May-2023	Asked if Chance is planning to put collars on moose.	The Chance Project Team confirmed they are not planning to put collars on moose.	Comment was addressed at the time it was shared. See **Section 8** for more information on Project-related effects on and mitigation measures for the PCH.
Community Open House Event	Gwich'in Tribal Council Gwich'in Participants Residents of Fort McPherson Residents of Tsiigehtchic Residents of Aklavik	07-Dec-2023	Expressed Elders' and the PCMB's concern that industrial development will negatively affect caribou. Described that caribou avoid development and then do not return. Explained that caribou travel through the Project footprint. Added that caribou used to migrate through that area, which makes it a big concern for the users of the PCH. Suggested that Chance have a meeting with caribou user groups.	Chance has scheduled with potentially affected First Nations and the PCMB. Chance stated that it is important to keep in mind that industrial development can have some negative effects on the environment, wildlife, and people. Chance explained that it is responsible for making recommendations to mitigate potential effects.	On December 20, 2023, a meeting was held to discuss effects on PCH and potential mitigations. Chance, PCMB, potentially affected First Nations, and wildlife consultants attended. See **Section 9** for more information on Project-related effects on and mitigation measures for the PCH.
Land and Resource Use					
Letter Community Open House Event	Gwich'in Tribal Council Gwich'in Participants Residents of Fort McPherson	22-Jan-2015 07-Dec-2023	Expressed concern for Project-related effects on climate change and associated changes to the land, weather, and	Chance acknowledged and recorded the comment. Chance stated the Project has put in place various measures to address the potential effects resulting from climate change.	In addition, for accounting for the effects of climate change regarding the Project, the Project also strives to establish a local oil and gas source for Yukon and neighbouring projects, ultimately lowering the carbon footprint on fuel consumption and greenhouse gas emissions. As an

Interaction Type	Respondent	Date	Comment / Issue	Chance Response at the Time of Engagement	Chance Response at Project Proposal Submission
	Residents of Tsiigehtchic Residents of Aklavik		wildlife on which the Gwich'in depend.	Additionally, the Project has prepared contingency plans to account for any slumps related to climate change.	exploratory initiative, emissions are primarily linked to camp operations, transportation, drilling, and seismic programs, with an estimate pending.
Meeting	Gwich'in Tribal Council	22-Jul-2020	Questioned whether there was an increased risk of ski-doo traffic, and how it would be monitored.	Chance acknowledged and recorded the comment. Chance created a traffic/access plan, restricting site access for safety. Chance will restrict access to authorized personnel. Chance is utilizing existing access. Chance conducted a study to observe human use in the area (e.g., monitoring snow tracks) and did not find evidence of people accessing the area at that time.	Comment was addressed at the time it was shared. See **Section 11** for more information on Project-related effects on and mitigation measures for land and resource use.
Meeting Document Sharing: Memorandum in Response to Gwich'in Tribal Council Comments	Gwich'in Tribal Council	16-Nov-2020 08-Jul-2020	Expressed concerns about trapping. Gwich'in Tribal Council identified that the Project footprint overlaps with Tetl'it Gwich'in traplines.	Chance acknowledged and recorded the comment. Chance invited the Gwich'in Tribal Council to send a wildlife monitor on-site during construction and operation activities.	Chance acknowledges concerns regarding effects on wildlife, wildlife habitat, trapping, and traditional activities. For more information on Project-related effects on wildlife and wildlife habitat and mitigation measures see **Section 8** of the Project Proposal.
Meeting	Gwich'in Tribal Council	03-Jun-2021	Requested information regarding MBC. Gwich'in Tribal Council identified quite a few relic sumps, outside of the Yukon, which have	Chance acknowledged and recorded the comment. Chance stated that the Eagle Plains region does not have enough water to create those erosional experiences/issues.	Chance is committed to providing technical information regarding soil composition.

Interaction Type	Respondent	Date	Comment / Issue	Chance Response at the Time of Engagement	Chance Response at Project Proposal Submission
			been exposed by water erosion.		
Community Open House Event	Gwich'in Tribal Council Gwich'in Participants Residents of Fort McPherson Residents of Tsiigehtchic Residents of Aklavik	07-Dec-2023	Stated that the maps that Gwich'in Tribal Council has are outdated and do not show the current uses of Gwich'in Participants. Noted that this does not mean that Gwich'in Participants are not using the Project footprint for traditional land use and resource uses.	The Chance Project Team acknowledged the comment and indicated that further engagement with Gwich'in Tribal Council will continue as the Project proceeds through the YESAB Executive Committee process.	Comment was addressed at the time it was shared.
Linear Features					
Meeting	Gwich'in Tribal Council	24-Apr-2018	Expressed concern about landscape level effects. The 325 km of seismic lines will affect people as they drive by Project on the Dempster Highway. Community members have expressed concern with the alteration to the landscape.	Chance acknowledged and recorded the concern regarding effects of seismic lines. Chance conducted a linear features study to understand potential Project-related linear disturbances including effects on predator and prey interactions. Chance utilizes design components, such as using meandering seismic lines, which aim to minimize visual disturbance and make it more difficult for predators and hunters to travel along the lines. Chance is open to further dialogue to best address this issue.	Chance acknowledges the concern and wants to continue discussions to minimize effects on potentially affected First Nations. The comment is addressed in **Section 11.3** of the Project Proposal documents.

Interaction Type	Respondent	Date	Comment / Issue	Chance Response at the Time of Engagement	Chance Response at Project Proposal Submission
Meeting	Gwich'in Tribal Council	24-Apr-2018 17-May-2023	Expressed concern with linear disturbance on predator and prey interactions. Recognized that this is a key concern for communities. Requested Chance consider how predators use linear disturbance.	Chance conducted a linear features study to understand potential Project-related linear disturbances including effects on predator and prey interactions. Chance shared the Linear Features Study with Gwich'in Tribal Council for their records.	Chance staff hired as wildlife monitors and security personnel will monitor access to the winter roads. See **Sections 11.3** and **9** of the Project Proposal for more information.
Document Sharing: Memorandum in Response to Gwich'in Tribal Council Comments	Gwich'in Tribal Council	08-Jul-2020	Requested Chance to avoid unnecessary degradation of the soil and destruction of wildlife habitat.	Chance acknowledged and recorded the comment. No further action was required. Chance shared the Project design (e.g., re-establishing winter roads and work during winter) was intended to minimize and/or eliminate potential effects on value such as soil, permafrost, vegetation, riparian areas, and wildlife habitat.	Comment was addressed at the time it was shared.
Permafrost and Terrain					
Meeting	Gwich'in Tribal Council	17-May-2023	Inquired whether buffers would be used to protect permafrost areas.	Chance acknowledged and recorded the comment. Chance responded that Project activities will not be adjacent to high sensitivity areas.	Chance created a constraints map to identify sensitive or high-quality environmental and heritage values where Project work should be avoided or minimized. See **Section 4** for more information.
Community Open House Event	Gwich'in Tribal Council Gwich'in Participants Residents of Inuvik	16-May-2023	Asked how much closer the drill got in areas where permafrost was burned from fire.	The Chance Project Team responded that vegetation affected by wildfire will grow back in 100 to 200 years. Shared that drilling will likely	Comment was addressed at the time it was shared.

Interaction Type	Respondent	Date	Comment / Issue	Chance Response at the Time of Engagement	Chance Response at Project Proposal Submission
				take place in areas where bedrock is near the surface to minimize thickening of the active layer (which could result in permafrost thawing). Confirmed areas sensitive to permafrost degradation will be avoided.	
Community Open House Event	Gwich'in Tribal Council Gwich'in Participants Residents of Fort McPherson Residents of Tsiigehtchic Residents of Aklavik	07-Dec-2023	Asked if there are slumps and/or erosion in the Project footprint.	The Chance Project Team shared that in general, there are areas of existing erosion and slumps, however they were classified in the exploration suitability as areas not ideal for development and to either avoid or engineer around. The Chance Project Team stated that they prepared the exploration activities to limit slumping. Chance added that normally, it maps the drilling location (100 m x 100m) and that it will put 6" mats on the whole operation.	A "Constraints Map" exercise was conducted to identify especially sensitive or high-quality environmental values where project work should be avoided. Constraints included permafrost/terrain sensitive areas to avoid. See **Section 4** for more information.
Community Open House Event	Gwich'in Tribal Council Gwich'in Participants Residents of Fort McPherson Residents of Tsiigehtchic Residents of Aklavik	07-Dec-2023	Asked what a "Mix Cover Zone" is.	Chance acknowledged and recorded the comment. Chance stated this will be the area where the sumps resulting from the exploration activities will be buried to protect the environment.	Comment was addressed at the time it was shared.

Interaction Type	Respondent	Date	Comment / Issue	Chance Response at the Time of Engagement	Chance Response at Project Proposal Submission
Heritage Resources					
Letter	Gwich'in Tribal Council	22-Jan-2015	Expressed concerns about the absence of Traditional Use/Knowledge studies and requested additional time to review the Project Proposal for supporting planning and mitigation development. Recognized worries about potential Project-related effects on traditional Tetł'it Gwich'in trails and the headwaters of Tth'an Dhidlii Njik ("Bone-they are scattered around-creek," also known as Dalglish Creek).	Chance acknowledged and recorded the comment.	Chance identified secondary sources of Traditional Knowledge for Gwich'in Tribal Council's review, comment, and permission to use in the Project Proposal. Chance assessed in Heritage Resources in **Section 10** of the Project Proposal.
Document Sharing: Memorandum in Response to Gwich'in Tribal Council Comments	Gwich'in Tribal Council	08-Jul-2020	Requested that the wildlife monitor be trained to identify archaeological materials and paleontological materials.	Chance acknowledged and recorded the comment. No response was provided at the time.	Chance will provide additional training in identification of both typical archaeological and paleontological materials to field technicians/environ. The Chance Project Team confirmed a *Chance Find Procedure* for the Project is being developed and stated potentially affected First Nations will be notified when the *Chance Find Procedure* is implemented.
Community Open House Event	Gwich'in Tribal Council Gwich'in Participants Residents of Inuvik	16-May-2023	Mentioned the importance of protecting archaeological,	The Chance Project Team responded that any archaeological and heritage resource discoveries in the Project footprint will be	Comment was addressed at the time it was shared. The Chance Project Team confirmed a *Chance Find Procedure* for the Project is being developed and stated potentially

Interaction Type	Respondent	Date	Comment / Issue	Chance Response at the Time of Engagement	Chance Response at Project Proposal Submission
			historical, and paleontological sites	protected from Project-related effects.	affected First Nations will be notified when the *Chance Find Procedure* is implemented.
Community Open House Event	Gwich'in Tribal Council Gwich'in Participants Residents of Inuvik	16-May-2023	Someone said the Borden number is a coordinate and known archaeological site that is not to be disturbed.	The Chance Project Team acknowledged and recorded the comment. Confirmed potentially affected First Nations would be contacted if archaeological and heritage resources are discovered to follow appropriate protection protocols.	Chance will work with potentially affected First Nations to support their involvement in future heritage resources studies. See **Section 10** for information on Project-related effects to and mitigation measures for heritage resources.
Meeting	Gwich'in Tribal Council	17-May-2023	Requested to be contacted if a burial site is discovered. Recommended that Chance engage Elders in development of the site.	Chance acknowledged and recorded the comment. Chance confirmed archaeology and heritage mitigation plans would be included in Chance's *Project Proposal* (Version 2, p. 30).	If human remains are encountered within the Project footprint, all work in the vicinity will stop immediately and First Nations, the Government of Yukon Heritage Resource Unit, and the RCMP will be contacted for guidance on how to proceed. This consultation will be guided by the principles laid out in the *Guidelines Respecting the Discovery of Human Remains and First Nation Burial Sites in the Yukon* document published by the Government of Yukon's Heritage Resource Unit. Chance will prepare a *Chance Find Procedure* which will apply during all Project activities.
Meeting	Gwich'in Tribal Council	17-May-2023	Asked if the *Project Proposal* (Version 2) will include a contact list if any archaeological or paleontological items were found.	Chance acknowledged and recorded the comment. Contact list will be provided later.	Comment was addressed at the time it was shared. The Chance Project Team confirmed a *Chance Find Procedure* for the Project is being developed and stated potentially affected First Nations will be notified when the *Chance Find Procedure* is

Interaction Type	Respondent	Date	Comment / Issue	Chance Response at the Time of Engagement	Chance Response at Project Proposal Submission
					implemented. The *Chance Find Procedure* will include a contact list.
Meeting	Gwich'in Tribal Council	04-Dec-2023	Expressed concern about the lack of cultural or heritage baseline data.	Chance to resend the heritage baseline studies to Gwich'in Tribal Council.	Comment was addressed at the time it was shared.
Community Open House Event	Gwich'in Tribal Council Gwich'in Participants Residents of Fort McPherson Residents of Tsiigehtchic Residents of Aklavik	07-Dec-2023	Asked if any grave sites have been discovered in the Project footprint.	The Chance Project Team confirmed no burial sites had been discovered in the Project footprint. Shared that remnants of tools were discovered. The Chance Project Team said the soil in the Project footprint is not ideal for preserving organic material. Confirmed protocols will be in place to protect cultural and heritage resources, including a *Chance Find Procedure*. The Chance Project Team said applicable heritage and conservation permits were required to complete archaeological and heritage resources studies for the Project. The permits ensure that consultants such as Ecofor follow archaeological and heritage resource study guidelines set by Government of Yukon Heritage. Added that any archaeological and heritage resource discoveries in the Project footprint will be protected from Project-related impacts.	If human remains are encountered within the Project footprint, all work in the vicinity will stop immediately and First Nations, the Government of Yukon Heritage Resource Unit, and the RCMP will be contacted for guidance on how to proceed. This consultation will be guided by the principles laid out in the *Guidelines Respecting the Discovery of Human Remains and First Nation Burial Sites in the Yukon* document published by the Government of Yukon's Heritage Resource Unit. Chance will prepare a Chance Find Procedure which will apply during all Project activities. Chance will work with potentially affected First Nations to support their involvement in future heritage resources studies. See **Section 10** for information on Project-related effects to and mitigation measures for heritage resources.

Interaction Type	Respondent	Date	Comment / Issue	Chance Response at the Time of Engagement	Chance Response at Project Proposal Submission
				Chance acknowledged and recorded the comment. Chance responded that no burials have been discovered. Studies have only uncovered tools. Chance explained that soil in the Project footprint is not ideal for preserving organic material. If any heritage resources, archaeological, or paleontological items are discovered, Chance will follow all legislation.	
Employment and Economy					
Letter Meeting Community Open House Events	Gwich'in Tribal Council Gwich'in Participants Residents of Fort McPherson Residents of Inuvik Residents of Tsiigehtchic Residents of Aklavik	24-Apr-2018 15-Nov-2018 16-May-2023 07-Dec-2023	Indicated interest in training and capacity building opportunities for their communities. Expressed interest in Project-related employment and training, scholarship, and capacity funding opportunities. Asked if the Project will be good for young people looking for work. Suggested Chance discuss job opportunities at the high school. Stated it would be preferential to hire more First Nations.	Chance strives to offer training, employment, and contracts to its First Nations partners. During its last drilling/seismic program, Chance successfully hired a workforce from the communities from Old Crow, Fort McPherson, Dawson, Whitehorse, and Inuvik (*Draft Project Description* (Version 2), p. 72). The Chance Project Team acknowledged the comment and expressed interest to share potential Project-related employment and training opportunities with youth, when available. Chance is committed to ongoing consultation and	Comment was addressed at the time it was shared.

Interaction Type	Respondent	Date	Comment / Issue	Chance Response at the Time of Engagement	Chance Response at Project Proposal Submission
				discussions around training, employment, and contracting opportunities with potentially affected First Nations.	
Community Open House Event	Gwich'in Tribal Council Gwich'in Participants Residents of Fort McPherson Residents of Tsiigehtchic Residents of Aklavik	07-Dec-2023	Asked if there are any monitors from Fort McPherson expected to work on the Project.	Chance acknowledged and recorded the comment. Chance stated that in 2014, the Project hired 30% of its seismic program labour from the greater Yukon Area. Chance added that there are other sectors that will benefit from the Project (e.g., transportation, food, monitors).	Chance strives to offer training, employment, and contracts to its First Nations partners. Chance is committed to ongoing consultation and discussions around training, employment, and contracting opportunities with potentially affected First Nations.
Community Open House Event	Gwich'in Tribal Council Gwich'in Participants Residents of Fort McPherson Residents of Tsiigehtchic Residents of Aklavik	07-Dec-2023	Asked how people can apply to potential job opportunities.	The Chance Project Team stated to contact Cindy Dickson or Greg Charlie for more information on how to apply for Project-related job opportunities. Cindy Dickson and Greg Charlie's contact information was provided on the Project handout distributed at the Open House.	Comment was addressed at the time it was shared.
Community Open House Event	Gwich'in Tribal Council Gwich'in Participants Residents of Fort McPherson Residents of Tsiigehtchic Residents of Aklavik	07-Dec-2023	Asked how many Gwich'in Participants have been involved in field studies. Stated economic opportunities are a topic of interest and should be shared with the community. Shared that the community needs to understand the opportunities	The Chance Project Team mentioned that Vuntut Gwitchin First Nation Citizens and Gwich'in Participants had been involved in pervious field studies and Chance exploration activities. Chance added that they had already received resumes from Gwich'in Participants and residents of Fort McPherson for the Project and will	Comment was addressed at the time it was shared.

Interaction Type	Respondent	Date	Comment / Issue	Chance Response at the Time of Engagement	Chance Response at Project Proposal Submission
			available before reviewing Project documentation and providing feedback.	continue to share information on Project-related employment opportunities with Gwich'in Tribal Council and Gwich'in Participants.	
Community Open House Event	Gwich'in Tribal Council Gwich'in Participants Residents of Fort McPherson Residents of Tsiigehtchic Residents of Aklavik	07-Dec-2023	Asked what Chance's procurement and hiring policies are. Stated that Gwich'in Participants want to see them sooner rather than later to understand what needs to be done to access potential employment and training opportunities.	Chance committed to sharing Project-related employment information with Gwich'in Participants and noted procurement and hiring policies had not yet been developed.	Comment was addressed at the time it was shared.
Community Open House Event	Gwich'in Tribal Council Gwich'in Participants Residents of Fort McPherson Residents of Tsiigehtchic Residents of Aklavik	07-Dec-2023	Stated it would be nice to have more First Nations involved in the Project. Added that a video showcasing "real work" on the ground makes more sense than graphs alone. Noted that the graphs and video of work should be combined.	Chance acknowledged and recorded the comment and will consider developing a new Project video that involves photo stills, video clips, and graphs, if the Project is approved.	Comment was addressed at the time it was shared.
Socio-Economics					
Document Sharing: Gwich'in Tribal Memorandum in Response to Gwich'in Tribal Council Comments	Gwich'in Tribal Council	08-Jul-2020	Indicated concern regarding increased traffic on the Dempster Highway.	Chance acknowledged and recorded the comment. Chance stated that Project design shows minimized traffic to the Project and on the Project site to avoid effects on wildlife (e.g., restricted access and speed limits).	Anticipated Project-related traffic and efforts to manage and limit traffic are described in **Sections 1 and 11**. Chance will limit traffic on the winter access roads to authorized personnel. Traffic will include approximately 8 to 9 light-weight service trucks daily (for supplies and personnel), 1 to 2 water

Interaction Type	Respondent	Date	Comment / Issue	Chance Response at the Time of Engagement	Chance Response at Project Proposal Submission
					trucks, and 1 fuel truck as frequently as exploration activities dictate (see **Sections 1 and 11**).
Mitigations and Monitoring					
Meeting	Gwich'in Tribal Council	22-Jul-2020	Requested bi-weekly updates on the findings of the wildlife monitor.	Chance acknowledged and recorded the comment. Chance committed to sending bi-weekly wildlife monitoring reports to Gwich'in Tribal Council.	Comment was addressed at the time it was shared.
Cumulative Effects					
Meeting	Gwich'in Tribal Council	01-Nov-2023	Expressed concern about cumulative effects in the Peel Watershed and cumulative effects of greenhouse gas emissions.	Chance acknowledged and recorded the comment.	See **Section 1, 10.6 and 11** of the Project Proposal for more information regarding cumulative effects.
Climate Change					
Community Open House Event	Gwich'in Tribal Council Gwich'in Participants Residents of Fort McPherson Residents of Tsiigehtchic Residents of Aklavik	07-Dec-2023	Asked what the Project will do to address potential effects resulting from climate change.	Chance stated the Project has put in place measures to address potential Project-related effects resulting from climate change. Added the Project has prepared contingency plans to account for any climate change-related effects to the Project such as slumps/erosion.	Comment was addressed at the time it was shared.

2.8.10 Ongoing Consultation and Engagement

Chance will continue to consult and engage Gwich'in Tribal Council and residents of Inuvik, Fort McPherson, Tsiigehtchic, and Aklavik following submission of the Project. Chance will refine the Program in response to feedback from Gwich'in Tribal during future Project phases, as needed. Planned ongoing consultation and engagement activities include (but are not limited to):

- Project communications (e.g., updates regarding schedule, permitting, monitoring activities, incorporation of Indigenous Knowledge to Project plans, and capacity funding);
- meetings to discuss Project-related effects, issues, and interests;
- opportunities to review and provide comment on Project plans and materials; and,
- opportunities to develop Project-related mitigation measures.

2.9 CONSULTATION AND ENGAGEMENT WITH VUNTUT GWITCHIN FIRST NATION AND RESIDENTS OF OLD CROW

Section 2.9 outlines consultation and engagement activities with Vuntut Gwitchin First Nation and residents of Old Crow. Information on Project notification, consultation and engagement planning, methods, activities, and agreements, issues, interests, input, and feedback shared through consultation and engagement activities are described in **Sections 2.9.1- 2.9.9.**

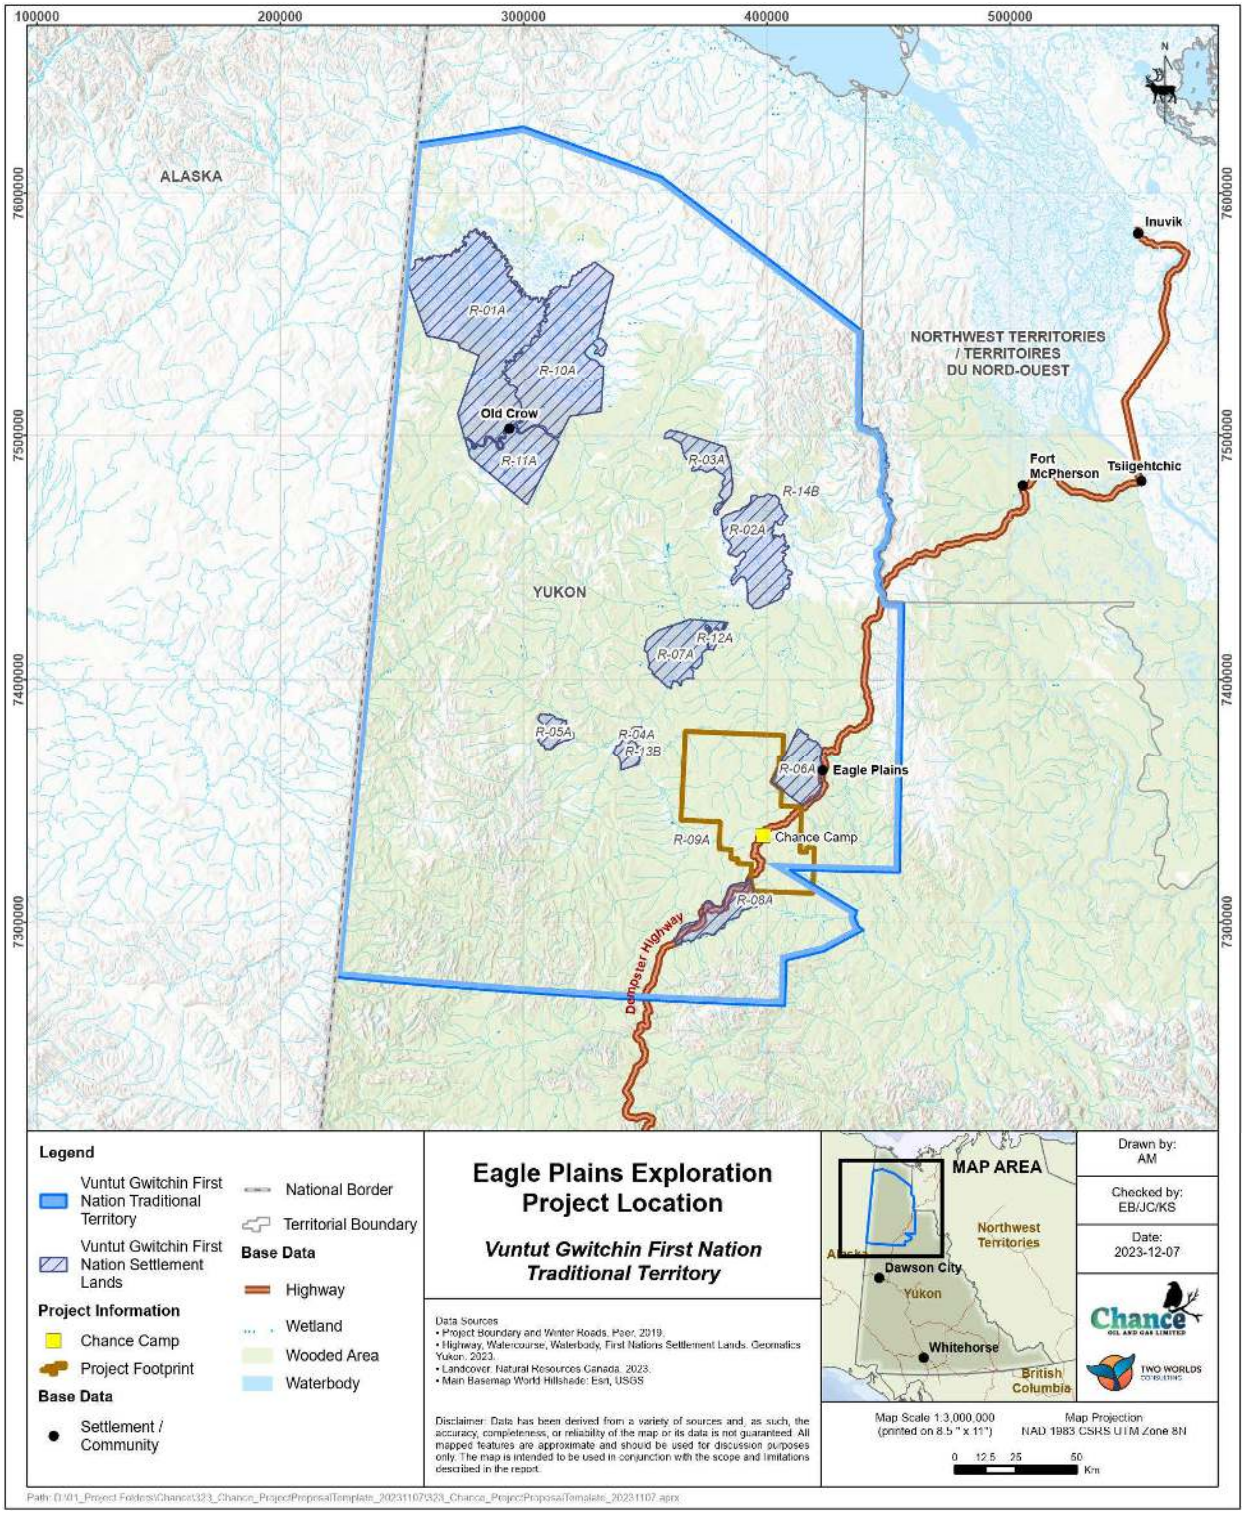
2.9.1 Community Profiles

2.9.1.1 Vuntut Gwitchin First Nation

> Old Crow derives its name from an Indian Chief, "Deetru` K`avihdik", which means "Crow May I Walk". Following his death in the 1870's, his people named the river, mountain, and area in his honor, thus being the community of Old Crow."
>
> (Vuntut Gwitchin First Nation n.d.)

Vuntut Gwitchin First Nation is located north of the Arctic Circle, in Old Crow, Yukon (Government of the Vuntut Gwitchin First Nation, n.d.-a). The community of Old Crow is 1 of 19 Gwitchin communities located in northern Alaska and Canada (Council of Yukon First Nations, n.d.). The Gwitchin Nation has a population of 7,500 people (Government of the Vuntut Gwitchin First Nation, n.d.-a) with more than 200 Citizens living in Old Crow as of 2021 (Government of Canada 2022).

Due to the seasonal migration routes of the PCH, Gwitchin Elders chose this area to call their home (Government of the Vuntut Gwitchin First Nation, n.d.-a). Vuntut Gwitchin First Nation Citizens frequently travel across their Traditional Territory to hunt, trap, gather, and fish (Vuntut Gwitchin First Nation, n.d.-a). The Vuntut Gwitchin First Nation Traditional Territory, presented in **Map 2-4**, is around 67,960 km² (Council of Yukon First Nations, n.d.).



Map 2-4: Vuntut Gwitchin First Nation Traditional Territory

The Vuntut Gwitchin is composed of one Chief and four councillors, in office for terms of 4 years (Government of the Vuntut Gwitchin First Nation, n.d.-b). The current Vuntut Gwitchin First Nation government was elected in November 2022 and sworn in on January 11, 2023, and is made up of: Chief Pauline Frost, Deputy Chief Debra-Leigh Reti, and Councillor Jeneen Njootli (Government of the Vuntut Gwitchin First Nation, n.d.-b). There is currently one Councillor vacancy. **Figure 2-5** visually represents the Vuntut Gwitchin First Nation governance structure.

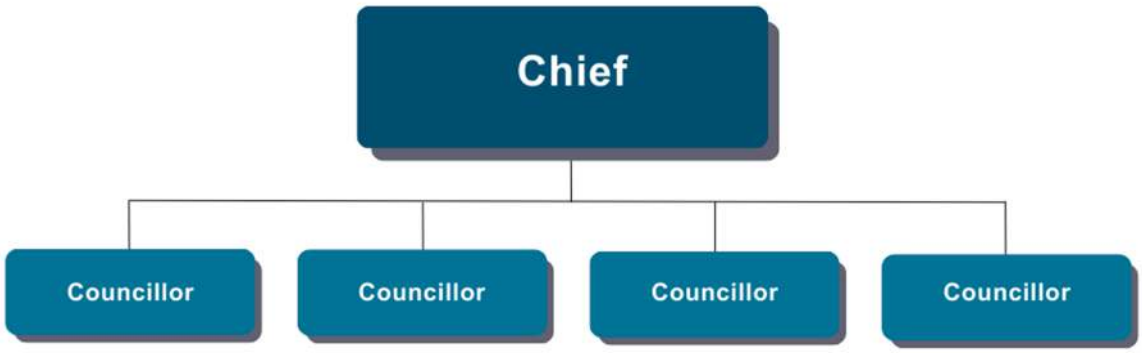


Figure 2-5. Vuntut Gwitchin First Nation Governance Structure (Government of the Vuntut Gwitchin First Nation n.d.)

Vuntut Gwitchin is the traditional name for Vuntut Gwitchin First Nation and can be translated as “People of the Lakes” and land of the PCH (Government of the Vuntut Gwitchin First Nation, n.d.-a). The name Vuntut Gwitchin is also derived from the muskrat trapping season (Vuntut Gwitchin First Nation, n.d.-a).

Vuntut Gwitchin First Nation Citizens are dependent on the PCH for their survival, cultural and spiritual well-being, and livelihood. The PCH are referred to as the centre of Gwitchin culture (Government of the Vuntut Gwitchin First Nation, n.d.-a; Vuntut Gwitchin First Nation, n.d.-a). All parts of the caribou are used for food, clothing, cultural objects, crafts, and other items (Government of the Vuntut Gwitchin First Nation, n.d.-a). The PCH passes through Old Crow in April, May, August, and September (Government of the Vuntut Gwitchin First Nation, n.d.-a). The caribou meat can be prepared in several ways (e.g., smoked, dried, boiled, and fried) and may be used in soups, roasts, jerky, chizi (pemmican), stews, and delicacies such as head soup (Government of the Vuntut Gwitchin First Nation, n.d.-a). The rest of the animal may be used to make clothing such as moccasins, gloves, boots, handbags, and many other items (Government of the Vuntut Gwitchin First Nation, n.d.-a). The PCH is vital to Vuntut Gwitchin First Nation Citizens and their culture.

2.9.1.2 Old Crow

Old Crow is the sole community found in northern Yukon, north of Dawson City (Vuntut Gwitchin First Nation, n.d.-a). Located on the Porcupine River, Old Crow has no road access and is only accessible by airplane, boat, or snowmobile (Government of the Vuntut Gwitchin First Nation, n.d.-a; Vuntut Gwitchin First Nation, n.d.-a). The community was founded in 1898, following the Klondike Gold Rush (Vuntut Gwitch’in 1996). In 2021, it had a population of approximately 235 people (Government of Canada 2022).

Old Crow is the home and administrative centre of the Vuntut Gwitchin Government. The community is governed by the Vuntut Gwitchin Government (Government of the Vuntut Gwitchin First Nation, n.d.-b). In

2021, industries with the largest proportion of the workforce were public administration, construction, and healthcare and social assistance (Government of Canada 2022).

The Old Crow Health Centre is the community's sole healthcare facility, offering general health services staffed by a full-time registered nurse and a Whitehorse physician on a monthly rotational basis (Vuntut Gwitchin First Nation 2023). For urgent emergency care and more complex health needs, residents are flown by medical evacuation (Medevac) to Whitehorse (Vuntut Gwitchin First Nation 2023). The current facility was built in 1960 and upgraded in the mid-1980s. A new health centre is currently being constructed, as well as housing, to replace the existing centre. The new centre will offer social services, home care services, mental wellness and substance use services, and community nursing health services. The construction project was anticipated to be completed in 2023 (Vuntut Gwitchin First Nation, n.d.-b; Government of Yukon 2019a).

Old Crow has one school (Kindergarten to Grade 12), Chief Zzeh Gittlit School. After Grade 9, students may choose to attend high school in Whitehorse and live in the Gadzoosdaa Student Residence (Vuntut Gwitchin First Nation, n.d.-b; Government of Yukon 2019b). There is a Yukon University campus that offers various certificates, diplomas, degrees, vocational, and upgrading programs and courses. The campus also provides public access to computers and Internet. Its staff offer employment skills assistance, academic advising, and counselling to residents (Yukon University, n.d.).

2.9.2 Project Notification

Chance initiated engagement with Vuntut Gwitchin First Nation on December 1, 2017. Chance sent Vuntut Gwitchin First Nation a letter (**Appendix 2-C Vuntut Gwitchin First Nation and Residents of Old Crow Consultation and Engagement Records**) about the *Communications and Engagement Plan* and developing a partnership with Vuntut Gwitchin First Nation.

Chance initiated consultation and engagement with residents of Old Crow at a community open house event on February 1, 2019.

2.9.3 Consultation and Engagement Planning

Chance developed a *Communication and Engagement Plan* (**Appendix 2-C**) outlining a proposed engagement approach with Vuntut Gwitchin First Nation. The *Communication and Engagement Plan* included information on communication pathways, meeting process, engagement documentation, and adaptive management.

Chance shared the *Communication and Engagement Plan* with Vuntut Gwitchin First Nation on March 28, 2018, for review and comment. The implementation of the proposed engagement approach remains ongoing.

2.9.4 Consultation and Engagement Methods

Consultation and engagement methods with Vuntut Gwitchin First Nation up to December 20, 2023 included

- meetings (virtual and in-person);

- letters;
- flyers and handouts;
- correspondence via phone call, text message, and email;
- community open house events;
- community leadership swearing-in event; and,
- information sharing (e.g., sharing Project documents for review and comment).

Chance will adjust consultation and engagement methods in response to feedback from Vuntut Gwitchin First Nation throughout the life of the Project.

Consultation and engagement methods with residents of Old Crow up to December 20, 2023 included community open house events as well as flyers and handouts.

2.9.5 Consultation and Engagement Activities

Table 2-6 outlines engagement activities undertaken with Vuntut Gwitchin First Nation and residents of Old Crow up to December 20, 2023.

Engagement materials such as presentations and handouts shared with Vuntut Gwitchin First Nation and residents of Old Crow have been compiled in **Appendix 2-C** of this Project Proposal. Where appendices were unavailable for compilation, **Table 2-6** indicates as such with an asterisk.

Table 2-6. Key Consultation and Engagement Activities with Vuntut Gwitchin First Nation and Residents of Old Crow

Recipient or Participant	Engagement Activity	Date	Description of Chance Consultation and Engagement
Vuntut Gwitchin First Nation	Correspondence via phone call, text message, and email	Ongoing	Coordinating engagement activities and sharing Project information.
Chance Vuntut Gwitchin First Nation Residents of Old Crow	Community Open House Event	15-Jun-2014	Held an open house at Chief Zzeh Gitlitt School Gym in Old Crow (**Appendix 2-C)***.
Chance Vuntut Gwitchin First Nation	Community Open House Event	16-Jun-2014	Held an open house at Vuntut Gwitchin First Nation's Whitehorse office for Vuntut Gwitchin First Nation Citizens to discuss a smaller-scale exploration project that was being submitting to the YESAB DO in Dawson (**Appendix 2-C**).
Chance Vuntut Gwitchin First Nation	Community Open House Event	16-Jun-2014	Held an open house at the Yukon Inn in Whitehorse with Vuntut Gwitchin First Nation Citizens to discuss the Project (**Appendix 2-C**).
Chance Vuntut Gwitchin First Nation Residents of Old Crow	Community Open House Event	17-Jun-2014	Held an open house at the Old Crow Community Hall. Chance provided Project information including a description of the targeted drilling program (**Appendix 2-C**).
Vuntut Gwitchin First Nation	Document sharing for records	26-Sep-2016	Provided a draft Engagement and Communication Strategy (**Appendix 2-C**).
Chance Vuntut Gwitchin First Nation	Letter	08-Sep-2017	Sent a letter stating their interests in achieving an *Engagement and Communication Plan* with Vuntut Gwitchin First Nation (**Appendix 2-C**).
Chance	Letter	12-Sep-2017	Sent a letter to Chance replying to their September 8, 2017 letter regarding the *Engagement and Communication Plan* (**Appendix 2-C**).
Vuntut Gwitchin First Nation	Letter	01-Dec-2017	Sent a letter regarding the *Communication and Engagement Plan* that Chance wishes to develop in partnership with Vuntut Gwitchin First Nation (**Appendix 2-C**)*.
Chance	Letter	11-Jan-2018	Received an email from Vuntut Gwitchin First Nation with a letter and the *Vuntut Gwitchin Government Oil and Gas Engagement Policy* (**Appendix 2-C**).
Chance Vuntut Gwitchin First Nation	Meeting	24-Jan-2018	Introduced the Vuntut Gwitchin First Nation Chief to the chair of Chance's Board of Directors. Discussed the draft *Vuntut Gwitchin Government Oil and Gas Engagement Policy,* and arrangements to develop a communications and engagement plan (**Appendix 2-C**)*.

Recipient or Participant	Engagement Activity	Date	Description of Chance Consultation and Engagement
Chance Vuntut Gwitchin First Nation	Meeting	22-Feb-2018	Discussed relationship building, the oil and gas industry, the Chance Community Relations Committee, the draft *Vuntut Gwitchin Government Oil and Gas Engagement Policy*, and community engagement for the Project (**Appendix 2-C**).
Chance Vuntut Gwitchin First Nation	Meeting	22-Mar-2018	Discussed the draft Schedule of Engagement, Chance Community Relations Committee Terms of Reference, and Chance Engagement and Communication Plan (**Appendix 2-C**)*.
Vuntut Gwitchin First Nation	Document sharing for review and comment	27-Mar-2018	Shared the Community Relations Terms of Reference (**Appendix 2-C**)*.
Vuntut Gwitchin First Nation	Document sharing for review and comment	28-Mar-2018	Shared the Draft Communication and Engagement Plan and the draft Schedule of Engagement (**Appendix 2-C**)*.
Vuntut Gwitchin First Nation	Document sharing for review and comment	27-Apr-2018	Shared the Vuntut Gwitchin and Chance Communication and Engagement Plan (**Appendix C-7**).
Chance Vuntut Gwitchin First Nation	Meeting	03-May-2018	Discussed revisions to the draft Vuntut Gwitchin and Chance Communication and Engagement Plan (**Appendix 2-C**)*.
Chance	Document sharing for records	15-May-2018	Received a revised copy of the *Vuntut Gwitchin and Chance Communication and Engagement Plan,* dated May 7, 2018, from Vuntut Gwitchin First Nation (**Appendix 2-C**)*.
Chance Vuntut Gwitchin First Nation	Meeting	19-Jun-2018	Discussed engagement activities in Old Crow during the week of July 9–13, 2018 (**Appendix 2-C**)*.
Chance Vuntut Gwitchin First Nation	Meeting	10-Jul-2018	Discussed Chance's land tenure status, Project plans, community pathways for oil and gas related matters, and collaborative consultation and engagement (**Appendix 2-C**)*.
Vuntut Gwitchin First Nation	Document sharing for review and comment	26-Jul-2018	Shared the 1-page draft *Community Event* document (**Appendix 2-C**)*.
Chance Vuntut Gwitchin First Nation	Meeting	11-Sep-2018	Met with Vuntut Gwitchin First Nation to develop a *Cooperation Agreement* (**Appendix 2-C**).
Chance Vuntut Gwitchin First Nation	Meeting	12-Sep-2018	Met with Vuntut Gwitchin First Nation to develop a *Cooperation Agreement* (**Appendix 2-C**).
Vuntut Gwitchin First Nation	Document sharing for review and comment	20-Sep-2018	Draft Cooperation Agreement and the Exploration Scenario's document (**Appendix 2-C**).

Recipient or Participant	Engagement Activity	Date	Description of Chance Consultation and Engagement
Vuntut Gwitchin First Nation	Letter	03-Oct-2018	Sent a letter to Vuntut Gwitchin First Nation to advise that Chance intended to relinquish its exploration rights to the entire Exploration Permit 0005 (EP). Chance noted the importance of protected areas and expressed interest in supporting Vuntut Gwitchin First Nation by surrendering this EP to facilitate the creation of the Habitat Protection Area (HPA) with no encumbrance of outside oil and gas rights. Chance added that they were giving Vuntut Gwitchin First Nation notice prior to informing the Government of Yukon of the relinquishment (**Appendix 2-C**)*.
Chance Vuntut Gwitchin First Nation	Meeting	04-Oct-2018	Reviewed the *Cooperation Agreement* (**Appendix 2-C**).
Chance	Letter	31-Oct-2018	Sent a letter to Chance thanking Chance for surrendering their oil and gas Exploration Rights to their permit #0005 ("EP5"). Vuntut Gwitchin First Nation stated this was viewed as a 'goodwill gesture' of cooperation and respect (**Appendix 2-C**).
Chance Vuntut Gwitchin First Nation	Meeting	12-Dec-2018	Discussed the Vuntut Gwitchin Government Oil and Gas Engagement Policy (**Appendix 2-C**).
Vuntut Gwitchin First Nation Chief and Council Natural Resources Committee	Meeting	29-Jan-2019	Discussed Chance's land tenure permits and exploration intentions and provided the opportunity for Vuntut Gwitchin First Nation to share feedback on and ask questions about the Project (**Appendix 2-C**).
Chance First Nation of Na-Cho Nyäk Dun Vuntut Gwitchin First Nation Gwich'in Tribal Council Government of Yukon	Meeting	01-Feb-2019	Discussed the First Nation engagement plans, the *Vuntut Gwitchin First Nation Oil and Gas Engagement Policy*, and the *Draft Project Description* (Version 1) (**Appendix 2-C**).
Vuntut Gwitchin First Nation	Letter	15-Mar-2019	Introduced Chance, provided a description of the *Oil and Gas Dispositions and Application*, *Confidentiality Agreement*, compliance records, and dispositions and wells (**Appendix 2-C**).
Vuntut Gwitchin First Nation	Document sharing for records	05-Jun-2019	Draft Project Description (Version 1) (**Appendix 2-C**).
Vuntut Gwitchin First Nation Residents of Old Crow	Community Dinner Event	06-Jun-2019	Gave a presentation and provided dinner to Vuntut Gwitchin First Nation and Old Crow Citizens.

Recipient or Participant	Engagement Activity	Date	Description of Chance Consultation and Engagement
			Discussed the draft *Project Description* (Version 1) and the annual reporting of the *Vuntut Gwitchin Government Oil and Gas Engagement Policy* (**Appendix 2-C**).
Vuntut Gwitchin First Nation	Document sharing for records	15-Jun-2019	Provided Vuntut Gwitchin First Nation with information on summer field work participation (**Appendix 2-C**).
Vuntut Gwitchin First Nation	Fieldwork (Email)	17-Jun-2019	Invited Vuntut Gwitchin First Nation to send 2 participants to join the planned environmental monitoring programs for the summer (**Appendix 2-C**).
Chance	Letter	10-Jul-2019	Sent a letter to Chance responding to notices submitted by Chance regarding the *Vuntut Gwitchin Government Oil and Gas Policy*, extension of oil and gas permits 0006-0011 and 0019, and Chance's proposed oil and gas activities in the Eagle Plains basin (**Appendix 2-C**).
Vuntut Gwitchin First Nation	Letter	15-Jul-2019	Expressed interest to meet with Vuntut Gwitchin First Nation in August 2019 to discuss capacity funding as well as consultation and engagement (**Appendix 2-C**).
Vuntut Gwitchin First Nation	Document sharing for review and comment	25-Jul-2019	Shared the Draft Implementation of the Vuntut Gwitchin Government and Chance Oil and Gas Communication and Engagement Plan Annual Report (**Appendix 2-C**).
Chance	Document sharing for records	30-Jul-2019	Sent Chance the signed Implementation of the Vuntut Gwitchin Government and Chance Oil and Gas Communication and Engagement Plan Annual Report (**Appendix 2-C**)*.
Chance	Letter	26-Aug-2019	Sent a letter to Chance to confirm the following notices were complete and sufficient, in accordance with Section 24 and 25 of the *Vuntut Gwitchin Government Oil and Gas Engagement Policy*: Chance's application to extend the term of oil and gas permits 0006-0011 and 0019 and notice of Chance's proposed oil and gas activities in Eagle Plains basin. Vuntut Gwitchin First Nation stated the *Vuntut Gwitchin Government Oil and Gas Engagement Policy* now would require the negotiation of a *Cooperation Agreement* between Vuntut Gwitchin Government and Chance (**Appendix 2-C**).
Chance Vuntut Gwitchin First Nation	Meeting	17-Oct-2019	Discussed a Project update, cooperation and collaboration, and the *Cooperation Agreement* (**Appendix 2-C**).
Chance Vuntut Gwitchin First Nation	Meeting	26–27-Nov-2019	Retained a third-party facilitator to mediate negotiation of the *Cooperation Agreement* required under Stage II of the *Vuntut Gwitchin Government Oil and Gas Engagement Policy*. Both parties met for 2 days (November 26 and

Recipient or Participant	Engagement Activity	Date	Description of Chance Consultation and Engagement
			November 27, 2019) to discuss objectives and content of the *Cooperation Agreement* (**Appendix 2-C**)*.
Vuntut Gwitchin First Nation	Document sharing for review and comment	04-Dec-2019	Provided Chance with a revised *Cooperation Agreement* (**Appendix 2-C**).
Chance	Document sharing for records	10-Dec-2019	Provided Chance with a *Work Plan* (**Appendix 2-C**).
Vuntut Gwitchin First Nation	Document sharing for records	12-Feb-2020	Provided the *Gap Analysis* to Vuntut Gwitchin First Nation (**Appendix 2-C**).
Chance	Letter	27-Feb-2020	Received a letter about Chance's request for a waiver of the requirement under the V*untut Gwitchin Government Oil and Gas Engagement Policy* and a *Benefits and Stewardship Agreement* with Chance. Vuntut Gwitchin First Nation advised Chance that their request for a waive of the requirement under the *Vuntut Gwitchin Government Oil and Gas Engagement Policy* had not been granted by the Vuntut Gwitchin First Nation Natural Resources Committee (**Appendix 2-C**).
Vuntut Gwitchin First Nation	Letter	10-Mar-2020	Stated that Chance is disappointed that the Vuntut Gwitchin First Nation Natural Resources Committee was not able to provide the waiver to accommodate the undertaking of the YESAB process. Details around the *Benefits and Stewardship Agreement* were disclosed. Expressed interest in a meeting or series of meetings between April 1 and 8, 2020 in Old Crow to discuss capacity funding and host a community open house event including dinner to provide a Project update (**Appendix 2-C**).
Chance	Letter	18-Mar-2020	Requested a meeting for further clarity on Chance's request of proposed topics of discussion outlined in the March 10, 2020 letter (**Appendix 2-C**).
Vuntut Gwitchin First Nation	Letter	09-Apr-2020	Advised Vuntut Gwitchin First Nation that Chance will comply with the *Vuntut Gwitchin Government Oil and Gas Engagement Policy*. Details around capacity funding were included. Chance stated virtual communications will be necessary due to the COVID-19 pandemic (**Appendix 2-C**).
Vuntut Gwitchin First Nation	Letter	20-Apr-2020	Advised Vuntut Gwitchin First Nation that Chance applied to extend tenure of a permit by 5 years that would expire on August 30, 2020 (**Appendix 2-C**).
Chance	Letter	04-May-2020	Expressed that communications and response time may be prolonged or delayed due to the COVID-19 pandemic (**Appendix 2-C**).

Recipient or Participant	Engagement Activity	Date	Description of Chance Consultation and Engagement
Vuntut Gwitchin First Nation	Letter	27-May-2020	Sent a letter to Vuntut Gwitchin First Nation confirming the completion of Section 24 requirements of the *Vuntut Gwitchin Government Oil and Gas Engagement Policy* (**Appendix 2-C**).
Vuntut Gwitchin First Nation	Letter	10-Jun-2020	Followed up on the notice of the Project for Eagle Plains Well Maintenance of Section 24 requirements of the *Vuntut Gwitchin Government Oil and Gas Engagement Policy* (**Appendix 2-C**).
Vuntut Gwitchin First Nation	Virtual meeting	09-Jul-2020	Provided a Project overview and answered questions from Vuntut Gwitchin First Nation (**Appendix 2-C**).
Vuntut Gwitchin First Nation	Document sharing for records	10-Jul-2020	Provided Vuntut Gwitchin First Nation the *COVID-19 Community Engagement and Consultation Procedures* document (**Appendix 2-C**).
Vuntut Gwitchin First Nation	Document sharing for review and comment	13-Jul-2020	Shared the Draft Implementation of the Vuntut Gwitchin Government and Chance Oil and Gas Communication and Engagement Plan Annual Report (**Appendix 2-C**).
Vuntut Gwitchin First Nation	Virtual meeting	21-Aug-2020	Discussed the *Cooperation Agreement* (**Appendix X**).
Vuntut Gwitchin First Nation	Meeting	03-Sep-2020	Held a hybrid meeting and discussed revisions to the proposed Eagle Plains Well Maintenance and Winter Activities and answered questions (**Appendix 2-C**).
Vuntut Gwitchin First Nation and Residents of Old Crow	Community Open House Event	03-Sep-2020	Hosted an open house in Old Crow and documented 11 Vuntut Gwitchin First Nation Citizens and residents of Old Crow attendees (**Appendix 2-C**)*.
Vuntut Gwitchin First Nation and Residents of Old Crow	Document sharing for records	03-Sep-2020	Provided a handout at the open house on September 3, 2020 in Old Crow. This handout outlined the mitigation measures and potential effects on the PCH (**Appendix 2-C**).
Vuntut Gwitchin First Nation	Document sharing for records	05-Sep-2020	Provided the draft Project Proposal for the Well Maintenance Program (**Appendix 2-C**).
Vuntut Gwitchin First Nation and Residents of Old Crow	Document sharing for records	07-Sep-2020	Summarized Vuntut Gwitchin issues and concerns regarding wildlife and Project effects from a meeting in Old Crow (**Appendix 2-C**)*.
Vuntut Gwitchin First Nation	Document sharing for records	16-Sep-2020	Shared the Yukon Oil and Gas Act Benefits Agreement (**Appendix 2-C**).
Vuntut Gwitchin First Nation Natural Resources Committee	Virtual meeting	31-Oct-2020	Provided a Project update and discussed workplans, the *Vuntut Gwitchin Government Oil and Engagement Policy* process, the Project Proposal, Project feedback, third-party support, YESAB pre-submission and submission

Recipient or Participant	Engagement Activity	Date	Description of Chance Consultation and Engagement
			consultation and engagement activities, and next steps. Details around capacity funding were also discussed (**Appendix 2-C**)*.
Vuntut Gwitchin First Nation Natural Resources Committee	Virtual meeting	03-Nov-2020	Explained the withdrawal of the Project Proposal from the Dawson City YESAB DO (**Appendix 2-C**).
Vuntut Gwitchin First Nation	Letter	17-Dec-2020	Shared a letter regarding the *Cooperation Agreement* (**Appendix 2-C**).
Vuntut Gwitchin First Nation	Virtual meeting	17-Dec-2020	Discussed the Project including well maintenance and winter activities and previous questions raised by Vuntut Gwitchin First Nation (**Appendix 2-C**).
Vuntut Gwitchin First Nation	Meeting	17-Feb-2021	Discussed capacity funding and the Project (**Appendix 2-C**).
Chance	Letter	31-Mar-2021	Received from Vuntut Gwitchin First Nation to discuss communication pathways, consultation and engagement including measures implemented by Vuntut Gwitchin First Nation before continuing engagement with Chance under stage 2 of the *Vuntut Gwitchin Government Oil and Gas Engagement Policy*, and non-compliance with the *Vuntut Gwitchin Government Oil and Gas Engagement Policy* (**Appendix 2-C**).
Vuntut Gwitchin First Nation	Letter	12-Apr-2021	Provided a letter to Chief Tizya-Tramm regarding the letter Chance received on March 31, 2021. Chance re-stated their intentions to engage respectfully and transparently with the Vuntut Gwitchin Government (**Appendix 2-C**).
Vuntut Gwitchin First Nation and Residents of Old Crow	Community Open House Event	20-Apr-2021	Hosted an open house at Chief Zzeh Gitlitt School in Old Crow. In total, 10 Vuntut Gwitchin First Nation Citizens and residents of Old Crow attended the open house (**Appendix 2-C**)*.
Vuntut Gwitchin First Nation and Residents of Old Crow	Community Open House Event	21-Apr-2021	Hosted an open house at Chief Zzeh Gitlitt School in Old Crow. In total, 7 Vuntut Gwitchin First Nation Citizens and residents of Old Crow attended the open house (**Appendix 2-C**)*.
Vuntut Gwitchin First Nation and Residents of Old Crow	Community Open House Event	18-May-2021	Hosted an open house in Old Crow. In total, 14 Vuntut Gwitchin First Nation Citizens and residents of Old Crow attended the event. Environmental Dynamics Inc. (EDI), Vertex, and Chance provided respective presentations on linear features, water quality, wildlife, birds, and fish studies, drilling, and the Project (**Appendix 2-C**)*.
Vuntut Gwitchin First Nation and Residents of Old Crow	Document sharing for records	09-Jun-2021	Shared handouts for open house events from April 20, 2021, April 21, 2021, and May 18, 2021. Chance also shared the presentation that was shared at these events (**Appendix 2-C**)*.
Vuntut Gwitchin First Nation	Document sharing for records	13-Jul-2021	Shared the *Vuntut Gwitchin Heritage Act* with Chance for documentation (**Appendix 2-C**).

Recipient or Participant	Engagement Activity	Date	Description of Chance Consultation and Engagement
Vuntut Gwitchin First Nation	Document for review and comment	19-Jul-2021	Shared the Draft *Implementation of the Vuntut Gwitchin Government and Chance Oil and Gas Communication and Engagement Plan Annual Report* (**Appendix 2-C**).
Vuntut Gwitchin First Nation and Residents of Old Crow	Community Open House Event	13-Oct-2021	Hosted an open house at Chief Zzeh Gitlitt School Gym in Old Crow. Attendees included approximately 43 Vuntut Gwitchin First Nation Citizens and residents of Old Crow. Chance presented on permafrost, seismic, and wildlife baseline studies (**Appendix 2-C**).
Vuntut Gwitchin First Nation	Letter	27-Oct-2021	Discussed capacity funding and repairing the relationship with Vuntut Gwitchin First Nation (**Appendix 2-C**).
Vuntut Gwitchin First Nation	Letter	01-Dec-2021	Requested a meeting with the Chief of Vuntut Gwitchin First Nation (**Appendix 2-C**).
First Nation of Na-Cho Nyäk Dun Vuntut Gwitchin First Nation Gwich'in Tribal Council Tr'ondëk Hwëch'in	Document sharing for records	17-Dec-2021	Shared a letter to the Government of Yukon, Land Tenure Extension Request for Exploration Permits 0008-0017, 0019 and 0020 ("Permits") (Appendix C-41) (**Appendix 2-C**).
Chance First Nation of Na-Cho Nyäk Dun Vuntut Gwitchin First Nation Gwich'in Tribal Council Government of Yukon	Document sharing for review and comment	20-Jan-2022	Provided an updated version of the Heritage Resource Impact Assessment: Eagle Plains Exploration Project 2022 Interim Report (22-22ASR) (**Appendix 2-C**).
Chance Vuntut Gwitchin First Nation Residents of Old Crow	Community Open House Event	05-May-2022	Held a community open house event in Old Crow to share Project information including heritage resources, permafrost, seismic testing, about wildlife studies. Attendees included approximately 29 Vuntut Gwitchin First Nation Citizens and residents of Old Crow (**Appendix 2-C**).
Chance Vuntut Gwitchin First Nation Residents of Old Crow	Community Open House Event	26-May-2022	Held a community open house event in Old Crow to share Project information. Attendees included approximately 13 Vuntut Gwitchin First Nation Citizens and residents of Old Crow. Chance presented on the details on the drilling program and wildlife baseline studies (**Appendix 2-C**).
Chance	Letter	05-Aug-2022	Sent Chance a letter on communication and engagement about the Project (**Appendix 2-C**).

Recipient or Participant	Engagement Activity	Date	Description of Chance Consultation and Engagement
Chance First Nation of Na-Cho Nyäk Dun Vuntut Gwitchin First Nation Gwich'in Tribal Council Government of Yukon	Document sharing for review and comment	29-Nov-2022	Provided an updated version of the Heritage Resource Impact Assessment: Eagle Plains Exploration Project 2022 Interim Report (22-22ASR) (**Appendix 2-C**).
Chance Leadership and technical advisors from: Gwich'in Tribal Council First Nation of Na-Cho Nyäk Dun Vuntut Gwitchin First Nation	Meeting	26-Jan-2023	Hosted an in-person meeting in Vancouver, BC to re-establish collaborative working relationships, discuss engagement preferences going forward, and provide a Project update (**Appendix 2-C**).
Chance First Nation of Na-Cho Nyäk Dun Vuntut Gwitchin First Nation Gwich'in Tribal Council Government of Yukon	Document sharing for review and comment	15-Mar-2023	Provided an updated version of the Heritage Resource Impact Assessment: Eagle Plains Exploration Project 2022 Interim Report (22-22ASR) (**Appendix 2-C**).
Vuntut Gwitchin First Nation	Letter	05-Apr-2023	Provided Project information, including an update on the *Draft Project Description* (Version 2) (**Appendix 2-C**).
Chance Vuntut Gwitchin First Nation Residents of Old Crow	Community Open House Event	15-May-2023	Travelled to Old Crow for an in-person community open house event. This event was cancelled due to the potential for a flash flood. Chance, with approval from Chief Frost, provided a catered dinner for leadership and community members at the Old Crow Community Centre. No summary was prepared because the event did not occur.
Chance Vuntut Gwitchin First Nation	Meeting	04-Aug-2023	Discussed a Project overview, design changes, baseline studies, and schedule, and engagement (**Appendix 2-C**).
Chance Vuntut Gwitchin First Nation	Meeting	25-Aug-2023	Discussed Chance's land tenure extensions and resources to support Vuntut Gwitchin First Nation's participation in the EC assessment process (**Appendix 2-C**)*.
Chance Vuntut Gwitchin First Nation	Meeting	13-Sep-2023	Discussed a Project update, baseline studies, and schedule and engagement (**Appendix 2-C**).

Recipient or Participant	Engagement Activity	Date	Description of Chance Consultation and Engagement
Chance Potentially affected First Nations Government of Canada YESAB Vuntut Gwitchin First Nation	Meeting	13-Oct-2023	Discussed the Project's assessment process including capacity funding and possible efficiencies through a coordinated approach (e.g., sharing consultants to support potentially affected First Nations' review of the Project Proposal) (**Appendix 2-C**).
Vuntut Gwitchin First Nation and Residents of Old Crow	Community Open House Event	06-Dec-2023	Held a focus group event in Old Crow to share Project information with presentations by technical experts from EDI, Ecofor, and Palmer. This included wildlife, fish and fish habitat, heritage resources, and permafrost presentations (**Appendix 2-C**).
First Nation of Na-Cho Nyäk Dun Gwich'in Tribal Council Porcupine Caribou Management Board Tr'ondëk Hwëch'in Vuntut Gwitchin First Nation Government of Yukon Chance EDI TWC	Meeting	20-Dec-2023	Discussed completed environmental baseline studies; potential effects on fish and wildlife and potential mitigation measures for fish and wildlife; potential PCH effects and potential mitigations; and the linear features study and North Yukon Land Use Planning conformity (**Appendix 2-C**).
* = Appendices not available at the time this section was drafted.			

2.9.6 Agreements

Chance and Vuntut Gwitchin First Nation signed a Benefits Agreement to support Vuntut Gwitchin First Nation's involvement in Chance well maintenance activities in Eagle Plains between 2011 and 2014. The agreement ended upon completion of the well maintenance activities in 2014.

Chance and Vuntut Gwitchin First Nation have not discussed any formal agreement for the Project to date. Though outside the scope of this Project, First Nation of Na-Cho Nyäk Dun, Vuntut Gwitchin First Nation, Government of Yukon, and Chance signed a Benefits Agreement on October 25, 2023 for their Well Maintenance Project.

2.9.7 Records Management

Appendix 2-C includes a record of contact documenting all consultation and engagement activities including emails, phone calls, text messages, letters, meetings, and events between Chance and Vuntut Gwitchin First Nation to up to December 20, 2023, and a record of contact documents all consultation and engagement activities with residents of Old Crow up to December 20, 2023 (**Appendix 2-C**).

2.9.8 Engagement Feedback (Effects, Issues, and Interests)

Chance sought to obtain feedback from potentially affected First Nations and residents of communities through Project engagement activities.

Table 2-7 presents effects, issues, and interests shared by Vuntut Gwitchin First Nation and residents of Old Crow with Chance up to December 20, 2023.

Table 2-7. Vuntut Gwitchin First Nation and Residents of Old Crow Key Issues and Consultation and Engagement Feedback

Interaction Type	Respondent	Date	Comment / Issue	Chance Response at the Time of Engagement	Chance Response at Project Proposal Submission
Project Design					
Email	Vuntut Gwitchin First Nation	20-Oct-2020	Requested information regarding Project costs, well permit areas, number of wells, and their locations.	Chance acknowledged and recorded the comment.	Chance modified the Project design to eliminate all-season roads from the Project. Instead, Chance will utilize winter ice roads. Chance acknowledges Vuntut Gwitchin First Nation's concerns about the number of well sites. **Section 1** describes how the well sites and design will incorporate key features to enhance efficiency, reduce waste, and minimize general effects on the surrounding environment. Chance will limit traffic on the winter access to authorized personnel. Traffic will include approximately 8 to 9 light-weight service trucks daily (for supplies and personnel), 1 to 2 water trucks, and 1 fuel truck as frequently as exploration activities dictate (see **Section 1**).
Community Open House Event	Vuntut Gwitchin First Nation Residents of Old Crow	05-May-2022	Expressed concern about drilling locations.	Chance acknowledged and recorded the comment.	Chance is committed to sharing well locations as locations become known. Chance created a constraints map to identify sensitive or high-quality environmental and heritage values where Project work should be avoided or minimized. See **Sections 1 and 3** for more information.
Community Open House Event	Vuntut Gwitchin First Nation Residents of Old Crow	06-Dec-2023	Inquired about previous drilling activity in the Eagle Plains Area. Asked if Chance has mapped out camps in the area.	Drilling occurred in 2012 and 2013. Drill holes were to up 3.4 km deep. The Project will utilize shallow drilling, involving drilling between 1,500 and 2,400 m. Fracking	Chance created a constraints map to identify sensitive or high-quality environmental and heritage values where Project work should be avoided or minimized. See Table 1-1: Summary of Key

Interaction Type	Respondent	Date	Comment / Issue	Chance Response at the Time of Engagement	Chance Response at Project Proposal Submission
				will not be utilized for this exploration Project. Chance is utilizing the Doors Yukon camp. No other specific work camps in the area will be used.	Activities for more information on the Chance camp.
Community Open House Event	Vuntut Gwitchin First Nation Residents of Old Crow	06-Dec-2023	Asked who granted Chance the authority to drill in the Project footprint.	The Chance Project Team said the Project is located off First Nation settlement land, and the Government of Yukon is the regulator that grants authority to drill.	Chance will consult and engage with potentially affected First Nations in a respectful manner and in accordance with First Nation protocols and preferences, and *YESAA* requirements. Comment was addressed at the time it was shared.
Community Open House Event	Vuntut Gwitchin First Nation Residents of Old Crow	06-Dec-2023	Asked why information around who has the authority to drill in the Project footprint is not known to the public.	The Chance Project Team responded that they want this information to get out. The Chance Project Team said there was a 7-year process to develop the *North Yukon Land Use Plan* including public meetings. The *North Yukon Land Use Plan* outlines designated high development areas. Chance shared that the *North Yukon Land Use Plan* was approved by Vuntut Gwitchin Government. The Chance Project Team also said that the YESAB process will dictate what the Project will be and stated YESAB is required to review all Project information and feedback from First Nations.	Comment was addressed at the time it was shared.

Interaction Type	Respondent	Date	Comment / Issue	Chance Response at the Time of Engagement	Chance Response at Project Proposal Submission
Community Open House Event	Vuntut Gwitchin First Nation Residents of Old Crow	06-Dec-2023	Asked if the Project is going to be conducted throughout the year.	The Chance Project Team confirmed exploration activities are planned for the winter months over a 10-year period.	Comment was addressed at the time it was shared.
Consultation and Engagement Process					
Meeting	Vuntut Gwitchin First Nation	22-Feb-2018 04-Oct-2018	Vuntut Gwitchin First Nation suggested extending the timeline for discussing the Agreement to allow for more community engagement, considering that the First Nation is new to the oil and gas industry and expressed a need for additional time to comprehend the Project.	Chance acknowledged and recorded the comment. Chance responded that they accept a longer timeline, with February 2019 remaining the target end date. No further action required at this time.	Chance is committed to building positive and open relationships with all potentially affected First Nations. Chance will consult and engage with potentially affected First Nations in a respectful manner and in accordance with First Nation protocols and preferences, and *YESAA* requirements.
Letter Letter Letter Email Letter Letter	Vuntut Gwitchin First Nation	10-Jul-2019 27-Feb-2020 18-Mar-2020 31-Mar-2020 31-Mar-2021 05-Aug-2022	Vuntut Gwitchin First Nation unable to proceed with consultation and engagement activities, until concerns around Chance's application to extend the term of oil and gas permits were discussed and addressed. Requested a meeting. Commented that Chance was in non-compliance with the Vuntut Gwitchin Government's *Oil and Gas Engagement Policy*. Stated that Chance is required to undertake consultation and engagement activities in a manner that complies with this policy.	Chance acknowledged and recorded the comment. Chance met with Vuntut Gwitchin First Nation Natural Resources Committee in August 2019 to discuss matters related to consultation and engagement. Chance advised Vuntut Gwitchin First Nation that it will comply with the Vuntut Gwitchin Government *Oil and Gas Engagement Policy* (April 9, 2020 letter).	Chance is committed to following the Vuntut Gwitchin Government's Oil and Gas Engagement Policy. Chance is committed to building positive and open relationships with all potentially affected First Nations. Chance will consult and engage with potentially affected First Nations in a respectful manner and in accordance with First Nation protocols and preferences, and *YESAA* requirements.

Interaction Type	Respondent	Date	Comment / Issue	Chance Response at the Time of Engagement	Chance Response at Project Proposal Submission
Community Open House Event	Vuntut Gwitchin First Nation Residents of Old Crow	26-May-2022	Vuntut Gwitchin First Nation requested additional consultation and engagement with community members.	Chance acknowledged and recorded the comment.	Chance is committed to building positive and open relationships with all potentially affected First Nations. Chance will consult and engage with potentially affected First Nations in a respectful manner and in accordance with First Nation protocols and preferences, and *YESAA* requirements. Chance conducted 8 socio-economic interviews with Vuntut Gwitchin First Nation staff and organizations and businesses in Old Crow. Of the 8 interviews, 5 interviews were conducted with Vuntut Gwitchin Government staff (3 in-person and 2 virtually) and 3 interviews were conducted with previous or current organization/business representatives.
Meeting	Vuntut Gwitchin First Nation	26-Jan-2023 04-Aug-2023	Requested a tripartite meeting between Vuntut Gwitchin First Nation, Chance, and the Government of Yukon.	Chance acknowledged and recorded the comment. Chance confirmed interest in understanding YESAB and Government of Yukon consultation's next steps. Chance will continue to attempt to meet with YESAB and Government of Yukon to confirm the common understanding of next consultation steps.	Chance is open to meeting with potentially affected First Nations and other parties throughout the Project's phases. Potentially affected First Nations, YESAB, Government of Yukon, Government of Canada, and Chance met on October 13, 2023, to discuss the Project's assessment process including consultation requirements and capacity funding opportunities for First Nations.
Meeting	Vuntut Gwitchin First Nation	03-Sep-2020	Commented that engagement is important to identify the valued ecological and socio-economic components and assess the Project in a detailed and meaningful way.	Chance acknowledged and recorded the comment. Chance confirmed that it wants to work with Vuntut Gwitchin First Nation.	Chance acknowledges the importance of consulting with potentially affected First Nations and values their input in the assessment process. Chance will consult and engage with potentially affected First Nations in a respectful manner and in accordance with

Interaction Type	Respondent	Date	Comment / Issue	Chance Response at the Time of Engagement	Chance Response at Project Proposal Submission
					First Nation protocols and preferences, and *YESAA* requirements. Potentially affected First Nations, YESAB, Government of Yukon, Government of Canada, and Chance met on October 13, 2023, to discuss the Project's assessment process including consultation requirements and capacity funding opportunities for First Nations
Letter Meeting	Vuntut Gwitchin First Nation	05-Aug-2022 13-Oct-2023	Stated that the Project Proposal should consider effects on the Gwich'in Nation as a whole, including Gwich'in in Alaska. Inquired about existing or potential consultation activities with Alaska and Alaskan First Nations regarding international transboundary lands.	Chance acknowledged and recorded the comment. Chance stated it is following *YESAA* consultation requirements and identified that *YESAA* does not include international transboundary consultation requirements.	Chance will consult and engage with potentially affected First Nations in a respectful manner and in accordance with First Nation protocols and preferences, and *YESAA* requirements.
Meeting	Vuntut Gwitchin First Nation	26-Jan-2023	Expressed concerns for Treaty and Aboriginal Rights, extent of engagement, permits with First Nation of Na-Cho Nyäk Dun, removal of 5 northern permits.	Chance acknowledged and recorded the comment. Chance responded that it is looking to understand how each Indigenous Nation would like to engage and share information. Chance stated that they are open to economic and environmental stewardship partnerships. Chance stated that they have hired consultants to assess potential Project-related effects on the Eagle Plains basin.	Chance shared the Draft *Collaboration Plan* outlining proposed consultation and engagement activities with Vuntut Gwitchin First Nation between October 2023 and February 2024 with Vuntut Gwitchin First Nation for review and comment. Chance is committed to refining future consultation and engagement in response to feedback from Vuntut Gwitchin First Nation.

Interaction Type	Respondent	Date	Comment / Issue	Chance Response at the Time of Engagement	Chance Response at Project Proposal Submission
Meeting	Vuntut Gwitchin First Nation	26-Jan-2023	Commented that there are important engagement protocols that requires building integrity and trust with Elders and communities.	Chance acknowledged and recorded the comment.	Chance is committed to building positive and open relationships with all potentially affected First Nations. Chance will consult and engage with potentially affected First Nations in a respectful manner and in accordance with First Nation protocols and preferences, and *YESAA* requirements.
Meeting	Vuntut Gwitchin First Nation	26-Jan-2023	Recognized the importance of re-establishing relationships with all northern Indigenous Nations.	Chance acknowledged and recorded the comment.	Chance is committed to building positive and open relationships with all potentially affected First Nations. Chance will consult and engage with potentially affected First Nations in a respectful manner and in accordance with First Nation protocols and preferences, and *YESAA* requirements.
Community Open House Event	Vuntut Gwitchin First Nation Residents of Old Crow	13-Sep-2023	Expressed a need for engagement and consultation with local communities. Shared individuals are seeking proper and informed engagement but are not for or against the Project.	Chance committed to continue engaging Vuntut Gwitchin First Nation on the Project. Chance planned another community event in Old Crow in December 2023 to discuss potential Project-related effects and proposed mitigation measures with Vuntut Gwitchin First Nation Citizens and residents of Old Crow.	Comment was addressed at the time it was shared.
Community Open House Event	Vuntut Gwitchin First Nation Residents of Old Crow	13-Sep-2023	Requested that Chance clarify where they have been, where they are now, and where they are headed.	The Chance Project Team shared information on the YESAB process for the Project. The Chance Project Team also prepared a 2-page handout to share Project information, a description of the YESAB	Comment was addressed at the time it was shared.

Interaction Type	Respondent	Date	Comment / Issue	Chance Response at the Time of Engagement	Chance Response at Project Proposal Submission
				assessment process, studies completed by Chance, the Project assessment process timeline, and key First Nation Project feedback and Chance's responses to shared feedback. This handout was also shared at community event in Old Crow in December 2023.	
Community Open House Event	Vuntut Gwitchin First Nation Residents of Old Crow	13-Sep-2023	Shared that quieter individuals are interested in questions asked. Suggested finding opportunities for local people to meet on behalf of the community.	Chance shared that they are available to discuss Project information with interested Vuntut Gwitchin First Nation Citizens and residents of Old Crow via phone or email. Chance made their contact information available in the Project handout that was distributed at the Open House.	Comment was addressed at the time it was shared.
Community Open House Event	Vuntut Gwitchin First Nation Residents of Old Crow	13-Sep-2023	Noted the importance of those with expertise presenting on permafrost, habitat, and water.	The Chance Project Team includes experts on permafrost, habitat, and water from EDI and Palmer. These experts were at the Open House to share information on and support discussions about their respective areas of expertise with Open House attendees.	Comment was addressed at the time it was shared.
Community Open House Event	Vuntut Gwitchin First Nation Residents of Old Crow	13-Sep-2023	Suggested more involvement in the Project from Vuntut Gwitchin First Nation leadership.	Chance acknowledged and shared this feedback with Vuntut Gwitchin First Nation leadership.	Comment was addressed at the time it was shared.

Interaction Type	Respondent	Date	Comment / Issue	Chance Response at the Time of Engagement	Chance Response at Project Proposal Submission
Community Open House Event	Vuntut Gwitchin First Nation Residents of Old Crow	13-Sep-2023	Appreciated the opportunity to learn more about the Project. Noted the Project Overview Video was very informative.	Chance acknowledged the comments.	Comment was addressed at the time it was shared.
Community Open House Event	Vuntut Gwitchin First Nation Residents of Old Crow	13-Sep-2023	Expressed interest in learning more about Chance and the Project.	Chance committed to continue engaging Vuntut Gwitchin First Nation on the Project. Chance planned another community event in Old Crow in December 2023 to discuss potential Project-related effects and proposed mitigation measures with Vuntut Gwitchin First Nation Citizens and residents of Old Crow.	Comment was addressed at the time it was shared.
Community Open House Event	Vuntut Gwitchin First Nation Residents of Old Crow	13-Sep-2023	Suggested Chance use a microphone during their next presentation to help all attendees hear the questions and comments from the crowd.	Chance designed a community event in December 2023 to support smaller, more focused group discussions about the Project. These discussions also supported better hearing conditions for attendees.	Comment was addressed at the time it was shared.
Community Open House Event	Vuntut Gwitchin First Nation Residents of Old Crow	13-Sep-2023	Shared the Open House was a great information session. Noted Chance provided good information on Project operations at the Open House.	Chance acknowledged the comments.	Comment was addressed at the time it was shared.
Community Open House Event	Vuntut Gwitchin First Nation Residents of Old Crow	13-Sep-2023	Suggested Chance discuss the Project with young people.	Chance acknowledged the comment and shared that all community-level events hosted by Chance are open to all ages. Chance also	Comment was addressed at the time it was shared.

Interaction Type	Respondent	Date	Comment / Issue	Chance Response at the Time of Engagement	Chance Response at Project Proposal Submission
				shared openness to connecting with interested young people about the Project via phone or email at any time. Chance made their contact information available in the Project handout that was distributed at the Open House.	
Community Open House Event	Vuntut Gwitchin First Nation Residents of Old Crow	13-Sep-2023	Shared the Open House was their first meeting about oil and gas and that there was lots of information. Expressed they do not understand but are getting there. Suggested Chance conduct additional consultation and engagement activities in Old Crow or send out Project information via paper.	Chance committed to continue engaging Vuntut Gwitchin First Nation on the Project. Chance planned another community event in Old Crow in December 2023 to discuss potential Project-related effects and proposed mitigation measures with Vuntut Gwitchin First Nation Citizens and residents of Old Crow. Chance also prepared and distributed a 2-page handout at this event to share Project information, a description of the YESAB assessment process, studies completed by Chance, the Project assessment process timeline, and key First Nation Project feedback and Chance's responses to shared feedback.	Comment was addressed at the time it was shared.
Community Open House Event	Vuntut Gwitchin First Nation Residents of Old Crow	06-Dec-2023	Inquired as to why other First Nations are being consulted about the Project.	Chance mentioned that the Project is consulting with other First Nations because the Eagle Plains Area is within their Traditional	Comment was addressed at the time it was shared.

Interaction Type	Respondent	Date	Comment / Issue	Chance Response at the Time of Engagement	Chance Response at Project Proposal Submission
				Territories. Chance is required to consult with others because of the Project location and potential effects.	
Community Open House Event	Vuntut Gwitchin First Nation Residents of Old Crow	06-Dec-2023	Expressed that Chance has provided clear and valuable information at the event. Added that the Project will be a significant project for Vuntut Gwitchin Government. Expressed that having two focus groups made it conducive for open communication. Expressed Chance explained the topics well. Shared that they were satisfied or very satisfied with the World Café.	Chance appreciated the feedback.	Comment was addressed at the time it was shared.
Community Open House Event	Vuntut Gwitchin First Nation Residents of Old Crow	06-Dec-2023	Asked if other governments are involved in studies completed for the Project. Inquired about Environmental Dynamic Inc.'s (EDI's) involvement with other governments.	The Chance Project Team said Chance is responsible for conducting the studies and uses available government data to support their studies. Added that Chance is required to conduct specific studies to meet requirements under the *Yukon Environmental Socio-economic Assessment Act*. The Chance Project Team shared that EDI supports the sonar project on the Porcupine River and works with the Vuntut Gwitchin First	Comment was addressed at the time it was shared.

Interaction Type	Respondent	Date	Comment / Issue	Chance Response at the Time of Engagement	Chance Response at Project Proposal Submission
				Nation on the winter road which involves DFO.	
Fish and Fish Habitat					
Community Open House Event	Vuntut Gwitchin First Nation Residents of Old Crow	06-Dec-2023	Asked if the Chance Project Team has a best practice for protecting fish and fish habitat or where the answers go from their studies.	Chance is required to follow fish guidelines set by DFO. Other guidelines for fish and fish habitat protection could come from YESAB or suggestions made by Vuntut Gwitchin First Nation and other potentially affected First Nations. Shared that there will be a public comment period once Chance submits the Project Proposal to YESAB in 2024. Added that anyone can download and submit comments on the Project Proposal directly to YESAB and/or Chance. The Chance Project Team noted that suggestions to protect fish and fish habitat shared today are helpful and could change the Project design. The Chance Project Team confirmed suggestions shared would be reflected in the Project Proposal. The Chance Project Team reminded attendees that the World Café event is one of multiple opportunities to ask questions about and shared feedback on the Project.	Comment was addressed at the time it was shared.

Interaction Type	Respondent	Date	Comment / Issue	Chance Response at the Time of Engagement	Chance Response at Project Proposal Submission
Traditional Knowledge					
Community Open House Event	Vuntut Gwitchin First Nation Residents of Old Crow	06-Dec-2023	Asked if Traditional Knowledge was considered in the Project design.	The Chance Project Team shared that Traditional Knowledge has been considered throughout the process and was provided information by Citizens of Old Crow on the winter range of the PCH. The Chance Project Team noted that PCH baseline studies captured both Traditional Knowledge and western science. The Chance Project Team engaged Vuntut Gwitchin First Nation Heritage on Traditional Knowledge confidentiality and use protocols. The Chance Project Team also shared existing secondary sources of Traditional Knowledge for Vuntut Gwitchin First Nation Heritage's review, comment, and permission for use. The Chance Project Team added that Traditional Knowledge is reflected in the Land and Resources section of the Project Proposal and has influenced the Project design (e.g., focusing on winter access roads versus all-season access roads). The Chance Project Team added that a request was brought in for the Project Team to halt	Comment was addressed at the time it was shared.

Interaction Type	Respondent	Date	Comment / Issue	Chance Response at the Time of Engagement	Chance Response at Project Proposal Submission
				building an all-season road until resources have been identified. It was requested that hunters were not allowed on the access road.	
Land and Resource Use					
Community Open House Event	Vuntut Gwitchin First Nation Residents of Old Crow	06-Dec-2023	Expressed concerns about the Project affecting Vuntut Gwitchin lands and the PCH. Added that Vuntut Gwitchin First Nation relies heavily on traditional food because of their remote location.	The Chance Project Team acknowledged the significance of PCH to Vuntut Gwitchin people. Added that Project-related effects to the PCH and land and resource use are described in the Project Proposal. Proposed mitigation measures for Project-related effects will also be described in the Project Proposal.	See **Section 11** for more information on potential Project-related effects on and mitigation measures for land and resource use.
Community Open House Event	Vuntut Gwitchin First Nation Residents of Old Crow	06-Dec-2023	Expressed concerns regarding subsistence hunting.	Chance confirmed that the land use will change and will affect subsistence hunting. Chance anticipates that there will be no long-term effects, but there will be an effect on caribou movement and subsistence harvesting in the short term.	See **Section 11** for more information on potential Project-related effects on and mitigation measures for land and resource use.
Water Resources					
Community Open House Events Meeting	Vuntut Gwitchin First Nation Residents of Old Crow	13-Oct-2021 05-May-2022 26-May-2022	Expressed concern for surface water effects and environmental protection. Expressed concern about water quality.	Chance acknowledged and recorded the comment.	Chance hosted a World Café event to share Project effects information with and obtain feedback on proposed mitigation measures from Vuntut Gwitchin First Nation Citizens and residents of Old Crow on December 6, 2023.

Interaction Type	Respondent	Date	Comment / Issue	Chance Response at the Time of Engagement	Chance Response at Project Proposal Submission
	Vuntut Gwitchin First Nation	04-Aug-2023	Stated that water is a key issue.		Chance shared baseline studies with Vuntut Gwitchin First Nation. Chance had a surface water quality and hydrology baseline report developed to inform background characteristics of surface water within the Regional Study Area. This report will guide any anticipated or intended water resource requirements. See the **Section 5** for mapping of riparian constraints within the Project footprint. Personnel trained in spill response will be onsite for the duration of the Project. In addition to spill response and cleanup, the spill response plan will include details on reporting requirements. More information about the type of materials used for the flow tests is available in **Section 1** of the Project Proposal. Chance will establish and enforce procedures to prevent unintended fluid release into the environment. Furthermore, an Emergency Spill and Response Plan and an Environmental Protection Plan will be devised, encompassing specifics on environmental monitoring and internal adherence to spill prevention and response measures. Chance will develop and implement procedures to prevent the inadvertent release of oil to the ground or waterways. See **Section 5** of the Project Proposal for more information.
Community Open House Event	Vuntut Gwitchin First Nation Residents of Old Crow	13-Sep-2023	Recommended Vuntut Gwitchin First Nation conduct research and information on	Chance acknowledged the importance for water quality/quantity data and community-led monitoring.	Comment was addressed at the time it was shared.

Interaction Type	Respondent	Date	Comment / Issue	Chance Response at the Time of Engagement	Chance Response at Project Proposal Submission
			water impacts (upstream and downstream water quality).	Chance committed to sharing water and fish studies completed for the Project with Vuntut Gwitchin First Nation leadership[8]. Chanced shared this feedback with Vuntut Gwitchin First Nation leadership.	
Community Open House Event	Vuntut Gwitchin First Nation Residents of Old Crow	06-Dec-2023	Asked how spills in rivers will be cleaned up. Asked how the Project will avoid creek crossings and erosion. Encouraged Chance to conduct drilling away from water resources. Asked what measures the Project is taking to protect creeks.	The Chance Project Team said studies completed for the Project have helped to identify potential low-impact drilling locations away from creeks and other water bodies. Added that the Project will avoid works near creeks as much as possible and that mitigation measures will be in place in case working near creeks becomes unavoidable. The Chance Project Team shared that Chance has spill plans and an emergency response plan, which is required by law for all oil and gas companies in Canada. Added that as part of the regulations, the well location needs to be a minimum of 100 m away from any water source. Added that the	Chance to list the fluids and materials necessary. Chance committed to developing plans to mitigate potential effects. Personnel trained in spill response will be onsite for the duration of the Project. In addition to spill response and cleanup, the spill response plan will include details on reporting requirements. More information about the type of materials used for the flow tests is available in **Section 1** of the Project Proposal. Chance will establish and enforce procedures to prevent unintended fluid release into the environment. Furthermore, an Emergency Spill and Response Plan and an Environmental Protection Plan will be devised, encompassing specifics on environmental monitoring and internal adherence to spill prevention and response measures.

[8] Two Worlds Consulting, on behalf of Chance, shared the Project's Fish and Fish Habitat and Surface Water Quality and Hydrology report with Vuntut Gwitchin First Nation's technical advisor and Executive Director on November 27, 2023 and offered to meet and discuss these studies, if interested.

Interaction Type	Respondent	Date	Comment / Issue	Chance Response at the Time of Engagement	Chance Response at Project Proposal Submission
				Chance Project Team must be aware of all spill incidents. Added that releases to the environment are expected to be highly unlikely.	Chance will develop and implement procedures to prevent the inadvertent release of oil to the ground or waterways.
Wildlife and Wildlife Habitat					
Meeting	Vuntut Gwitchin First Nation	03-Sep-2020	Expressed concern for effects to caribou and moose.	Chance acknowledged and recorded the comment. Chance stated a desire to work with lands technical staff to gather information on interests in the Project footprint.	Chance created a constraints map to identify sensitive or high-quality environmental and heritage values where Project work should be avoided or minimized. See **Sections 8 and 9** for more information. Chance's Wildlife Baseline Study summarizes existing baseline information for moose and developed a habitat model for the species within the Eagle Plains Regional Study Area (RSA). The habitat model quantifies the suitability, amount, and distribution of potential habitat for moose in the RSA. This information will be used to assess the Project's potential effects on moose and develop measures to mitigate effects if required (EDI, 2022, p. 87). EDI reviewed telemetry data and analysis outputs from the Porcupine Caribou Technical Committee to quantify the degree of seasonal range overlap by the PCH with the Project RSA during late fall and winter, when seasonal range use overlaps the RSA (EDI, 2022, p. 112). See **Sections 8** and **9** of the Project Proposal for more information on potential Project effects on moose and caribou.

Interaction Type	Respondent	Date	Comment / Issue	Chance Response at the Time of Engagement	Chance Response at Project Proposal Submission
Meeting	Vuntut Gwitchin First Nation	03-Sep-2020	Expressed concern for wolves.	Chance acknowledged and recorded the comment. Chance stated that wolves are not near the road as there is 24-hour road use. There will also be wildlife monitors present and ready to report sightings.	Chance conducted a *Linear Features Study* to understand the functional effect of existing linear features in the Project footprint, focused on wildlife, which was shared with Vuntut Gwitchin First Nation. The Project effects assessment includes an evaluation of the creation of new linear features, as well as an assessment of cumulative effects on which the Project may contribute. The Project is focused on newer, low-impact seismic technology. See **Sections 8** and **9** of the Project Proposal for more information on the potential effects of the Project on wolf prey species, including moose and caribou.
Letter	Vuntut Gwitchin First Nation	05-Aug-2022	Expressed concern that the Project will create human access and commented that the ecosystem has been protected by its inaccessibility.	Chance acknowledged and recorded the comment.	Chance is committed to controlling and restricting public use of its access roads. Chance recognizes this is a concern and will engage potentially affected First Nations further on this issue. Chance will limit traffic on the winter access to authorized personnel. Traffic will include approximately 8 to 9 light-weight service trucks daily (for supplies and personnel), 1 to 2 water trucks, and 1 fuel truck as frequently as exploration activities dictate (see **Section 1**).
Community Open House Event	Vuntut Gwitchin First Nation Residents of Old Crow	06-Dec-2023	Inquired about Chance's fish guidelines for the Project and expressed interest in seeing clear guidelines to protect fish..	The Chance Project Team confirmed fish guidelines for the Project will follow guidelines set by the Department of Fisheries and Oceans (DFO) Canada. Measures will be outlined in the Project Proposal.	Comment was addressed at the time it was shared.

Interaction Type	Respondent	Date	Comment / Issue	Chance Response at the Time of Engagement	Chance Response at Project Proposal Submission
Community Open House Event	Vuntut Gwitchin First Nation Residents of Old Crow	06-Dec-2023	Inquired about differences in monitoring outcomes between lake fish and river fish. Identified that different species are found in each.	Monitoring efforts did identify arctic grayling but did not detect any salmon species. Chance is only monitoring river systems and not lakes.	Chance created a constraints map to identify sensitive or high-quality environmental and heritage values where Project work should be avoided or minimized. See **Section 3 and 6** for more information.
Community Open House Event	Vuntut Gwitchin First Nation Residents of Old Crow	06-Dec-2023	Inquired about the Project's strategies for safeguarding riparian areas within the Project footprint.	Chance has identified high value riparian areas; these areas will be avoided as much as possible.	Chance shared that winter exploration will reduce negative effects on riparian areas. The construction and use of winter roads will minimize effects on surface vegetation. Chance shared that winter roads follow the height of land avoiding riparian areas and water bodies. All activities occur away from riparian areas and there are no stream crossings associated with the winter roads. Mitigation measures are expected to address potential effects on water resources and fish. Residual effects on these values are expected to be negligible. See **Sections 5** and **6** of the Project Proposal for more details. Chance created a constraints map to identify sensitive or high-quality environmental and heritage values where Project work should be avoided or minimized. See **Section 3** for more information.
Community Open House Event	Vuntut Gwitchin First Nation Residents of Old Crow	06-Dec-2023	Inquired about a wildlife monitoring program	The Chance Project Team said there will be a wildlife monitoring program throughout the Project that prioritizes hiring First Nation Citizens.	Comment was addressed at the time it was shared.

Interaction Type	Respondent	Date	Comment / Issue	Chance Response at the Time of Engagement	Chance Response at Project Proposal Submission
Porcupine Caribou Herd					
Meeting Community Open House Events Letter	Vuntut Gwitchin First Nation Residents of Old Crow	03-Sep-2020 13-Oct-2021 05-May-2022 04-Aug-2023 05-Aug-2022	Expressed concerns regarding effects on caribou and specifically for the PCH.	Chance acknowledged and recorded the comment. Chance stated a desire to work with lands technical staff to gather information on interests in the Project footprint. Chance stated the topics would be included in the draft Project Proposal and Chance is open to discussing these topics with Vuntut Gwitchin First Nation.	Chance acknowledges the important cultural value of the PCH to the Gwich'in. Chance is committed to reducing potential negative effects on the PCH and other wildlife. Chance hosted a World Café event to share Project effects information with and obtain feedback on proposed mitigation measures from Vuntut Gwitchin First Nation Citizens and residents of Old Crow on December 6, 2023.Chance shared baseline studies with Vuntut Gwitchin First Nation on the PCH. Chance created a constraints map to identify sensitive or high-quality environmental and heritage values where Project work should be avoided or minimized. See **Sections 3 and 9** for more information. See **Section 9** of the Project Proposal for more information on potential Project effects on the PCH.
Meeting	Vuntut Gwitchin First Nation	03-Sep-2020	Expressed concern for wolves using seismic cut lines and winter trails to hunt caribou.	Chance acknowledged and recorded the comment. Chance stated that wolves are not near the road as there is 24-hour road use. There will also be wildlife monitors present and ready to report sightings.	Chance assessed the potential effects of the Project on caribou mortality, including facilitated predation by wolves. See **Section 9** of the Project Proposal for more information.
Community Open House Event	Vuntut Gwitchin First Nation Residents of Old Crow	13-Sep-2023	Expressed concern for a lack of engagement and consultation with the PCMB. Shared concern for caribou showing signs of impacts,	The Chance Project Team discussed the data received from the PCMB and stated the Caribou Effects Assessment in the Project	See **Section 9** for more information on potential Project-related effects on and mitigation measures for the PCH.

Interaction Type	Respondent	Date	Comment / Issue	Chance Response at the Time of Engagement	Chance Response at Project Proposal Submission
			including changes to hunting practices due to development in the region. It was mentioned that Project analysis should be discussed with PCMB. Expressed concerns for caribou and stated that 30 wells over 10 years is concerning. Added that wildfires are destroying habitat range (including reduced blueberry harvests), which is further impacting caribou. Noted the importance of consultation with PCMB.	Proposal will be shared with the PCMB before it is submitted to YESAB in February 2024. Chance scheduled a Project overview meeting with PCMB on December 1, 2023 and a workshop on December 20, 2023 with technical advisors from the potentially affected First Nations and the PCMB to discuss PCH studies completed for the Project as well as potential Project-related effects to the PCH and proposed mitigation measures to protect the PCH.	
Community Open House Event	Vuntut Gwitchin First Nation Residents of Old Crow	06-Dec-2023	Expressed concern for caribou and declines in northern caribou species.	Chance responded that this will be addressed in the Project Proposal.	See **Section 9** for more information on potential Project-related effects on and mitigation measures for the PCH.
Community Open House Event	Vuntut Gwitchin First Nation Residents of Old Crow	06-Dec-2023	Asked what information the Chance Project Team had received from the PCMB.	The Chance Project Team confirmed that a lot of information had been received from the PCMB. Added that the PCMB provided Chance/EDI with collared data and that Chance shared Project information and wildlife studies with the PCMB technical committee per the PCMB's direction. The Chance Project Team shared that Chance met with	Comment was addressed at the time it was shared.

Interaction Type	Respondent	Date	Comment / Issue	Chance Response at the Time of Engagement	Chance Response at Project Proposal Submission
				the PCMB on December 1st to discuss the Project and conducted a technical working group meeting with the PCBM on the Porcupine Caribou Herd on December 20th.	
Community Open House Event	Vuntut Gwitchin First Nation Residents of Old Crow	06-Dec-2023	Inquired about the decline of the northern caribou species.	The Chance Team acknowledge the concern about reported declines in caribou numbers, and that several herds are showing signs of recovery, and noted that the Porcupine Caribou Herd is at the largest numbers ever recorded.	Comment was addressed at the time it was shared.
Community Open House Event	Vuntut Gwitchin First Nation Residents of Old Crow	06-Dec-2023	Requested that meat from a caribou killed by a predator be brought to Vuntut Gwitchin First Nation.	The Chance Project Team said typically the Government of Yukon and Environment and Climate Change Canada want to inspect the carcass. The Chance Project Team confirmed looking into the viability of sharing caribou meat with Vuntut Gwitchin First Nation. Added that while drilling, employees are to let the caribou move through the Project site unimpeded. The Chance Project Team explained that caribou are expected to adapt to the drills if they are not seen as predators.	Comment was addressed at the time it was shared. See **Section 9** for more information on potential Project-related effects on and mitigation measures for the PCH.

Interaction Type	Respondent	Date	Comment / Issue	Chance Response at the Time of Engagement	Chance Response at Project Proposal Submission
Community Open House Event	Vuntut Gwitchin First Nation Residents of Old Crow	06-Dec-2023	Noted that a lot of caribou like to stay along the winter roads.	The Chance Project Team agreed based on observations from the 2013/2014 seismic work, and noted this behaviour.	Comment was addressed at the time it was shared. See **Section 9** for more information on potential Project-related effects on and mitigation measures for the PCH.
Permafrost and Terrain					
Community Open House Event Community Open House Event Meeting	Vuntut Gwitchin First Nation Residents of Old Crow Vuntut Gwitchin First Nation	13-Oct-2021 05-May-2022 04-Aug-2023 06-Dec-2023	Expressed concern about permafrost effects. Stated that permafrost is a key issue.	Chance acknowledged and recorded the comment.	Chance hosted topic-specific focus group discussions to share potential Project effects information with and obtain feedback on mitigation measures from Vuntut Gwitchin First Nation and residents of Old Crow on December 6, 2023. Chance created a constraints map to identify sensitive or high-quality environmental and heritage values where Project work should be avoided or minimized. See **Section 3** for more information. See **Section 4** of the Project Proposal for more information on potential Project-related effects on and mitigation measures for permafrost.
Community Open House Event	Vuntut Gwitchin First Nation Residents of Old Crow	06-Dec-2023	Asked if the Surficial Geology Mapping and Road and Wellpad Suitability for Exploration maps shared on the permafrost posterboard were accurate.	Chance clarified that the maps been field verified to a level consistent with professional standards, and adjusted using data collected in field (i.e., temperature sensors and surface drilling. had been ground tested using sensors).	Comment was addressed at the time it was shared. See **Section 4** of the Project Proposal for more information on potential Project-related effects on and mitigation measures to for permafrost.
Community Open House Event	Vuntut Gwitchin First Nation	06-Dec-2023	Asked if Palmer was a private company or a government office.	Chance confirmed that Palmer is a privately owned company. Shared that Palmer hires registered	Comment was addressed at the time it was shared. See **Section 4** of the Project Proposal for more information on potential Project-

Interaction Type	Respondent	Date	Comment / Issue	Chance Response at the Time of Engagement	Chance Response at Project Proposal Submission
	Residents of Old Crow			professional geologists and geo-scientists who are bound by ethical standards to present accurate terrain and permafrost information.	related effects on and mitigation measures for permafrost.
Community Open House Event	Vuntut Gwitchin First Nation Residents of Old Crow	06-Dec-2023	Asked if permafrost is under the whole Project footprint.	The Chance Project Team stated that they are trying to avoid areas that are ice-rich. Added that areas containing silts and clays will thaw the permafrost more quickly than areas without silts and clays. The Chance Project Team noted that Chance will utilize the suitability map prepared by Palmer to design winter access road and drilling locations.	Comment was addressed at the time it was shared. See **Section 4** of the Project Proposal for more information on potential Project-related effects on and mitigation measures for permafrost.
Community Open House Event	Vuntut Gwitchin First Nation Residents of Old Crow	06-Dec-2023	Asked if the temperature of the ground has been warmer due to climate change.	The Chance Project Team confirmed data had only been collected over the past few years; changes in climate are measured on a longer time scale.	Comment was addressed at the time it was shared. See **Section 4** of the Project Proposal for more information on potential Project-related effects on and mitigation measures for permafrost.
Community Open House Event	Vuntut Gwitchin First Nation Residents of Old Crow	06-Dec-2023	Asked if the Project footprint has been hit by wildfires.	The Chance Project Team responded that wildfires have hit the Project footprint which can cause permafrost to reduce and increase the active layer. Added that wildfires damage permafrost, but vegetation helps to insulate the permafrost in areas not damaged by wildfire.	Comment was addressed at the time it was shared. See **Section 4** of the Project Proposal for more information on potential Project-related effects on and mitigation measures for permafrost.

Interaction Type	Respondent	Date	Comment / Issue	Chance Response at the Time of Engagement	Chance Response at Project Proposal Submission
Community Open House Event	Vuntut Gwitchin First Nation Residents of Old Crow	06-Dec-2023	Asked what was identified in the permafrost study.	The Chance Project Team said the studies identified areas and thickness of permafrost. Added that this data will help create a baseline to understand potential future impacts to permafrost in the area.	Comment was addressed at the time it was shared. See **Section 4** of the Project Proposal for more information on potential Project-related effects on and mitigation measures for permafrost.
Community Open House Event	Vuntut Gwitchin First Nation Residents of Old Crow	06-Dec-2023	Asked about the depth of the permafrost.	The Chance Project Team said the depth of permafrost varies across the Project footprint. Palmer's drilling work shows that the active layer is 0.45 to 0.9 m thick in fine-grained soils, below wetlands, and in valley bottoms. In coarse-grained soils, it is more than 0.9 m thick. Areas recently burned by wildfire have active layers that are more than 1 m thick, possibly much more.	Comment was addressed at the time it was shared. See **Section 4** of the Project Proposal for more information on potential Project-related effects on and mitigation measures for permafrost.
Community Open House Event	Vuntut Gwitchin First Nation Residents of Old Crow	06-Dec-2023	Asked what the Project will do to avoid drilling in discontinuous permafrost areas.	The Chance Project Team noted that the Project will take action to prevent drilling in discontinuous permafrost areas.	Comment was addressed at the time it was shared. See **Section 4** of the Project Proposal for more information on potential Project-related effects on and mitigation measures for permafrost.
Community Open House Event	Vuntut Gwitchin First Nation Residents of Old Crow	06-Dec-2023	Noted that some people in Old Crow have noticed changes in soil/permafrost conditions.	The Chance Project Team said that happens when the permafrost starts to unfreeze.	Comment was addressed at the time it was shared. See **Section 4** of the Project Proposal for more information on potential Project-related effects on and mitigation measures for permafrost.

Interaction Type	Respondent	Date	Comment / Issue	Chance Response at the Time of Engagement	Chance Response at Project Proposal Submission
Employment and Economy					
Email Community Open House Event	Vuntut Gwitchin First Nation Vuntut Gwitchin First Nation Residents of Old Crow	20-Jan-2020 20-Oct-2020 05-May-2022 06-Dec-2023	Requested information about potential job opportunities and training needs. Stated employment opportunities are important for Old Crow. Requested that Chance provide a deeper understanding of potential employment, and training and contracting opportunities. Inquired whether Vuntut Gwitchin First Nation employees had been involved in recent studies. Recommended wildlife monitors should be from Old Crow.	Chance acknowledged and recorded the comment. The Chance Project Team said wildlife monitoring opportunities will be prioritized for Vuntut Gwitchin First Nation Citizens.	Chance will offer training, employment, and contracts to its First Nations partners. Most employment opportunities will be connected to camp operations, construction of roads and seismic lines, and environmental monitoring. During its last drilling/seismic program, Chance hired a workforce from the communities of Old Crow, Fort McPherson, Dawson, Whitehorse, and Inuvik (See **Section 11**). Chance is committed to ongoing consultation and discussions around training, employment, and contracting opportunities with potentially affected First Nations.
Community Open House Event	Vuntut Gwitchin First Nation Residents of Old Crow	13-Sep-2023	Suggested that there would be more demand for Project-related job opportunities if a worker could keep job-related equipment as part of their compensation (e.g., chainsaw).	Chance acknowledged the comment and would investigate opportunities for employees to keep job-related equipment as part of their compensation.	Comment was addressed at the time it was shared. See **Section 11** of the Project Proposal for more information on potential Project-related effects on and mitigation measures for employment and economy.
Community Open House Event	Vuntut Gwitchin First Nation Residents of Old Crow	13-Sep-2023	Expressed hope for Project-related job opportunities, including opportunities for youth.	Chance responded that potentially affected First Nations including youth would be prioritized for Project-related job opportunities.	Comment was addressed at the time it was shared. See **Section 11** of the Project Proposal for more information on potential Project-related effects on and mitigation measures for employment and economy.

Interaction Type	Respondent	Date	Comment / Issue	Chance Response at the Time of Engagement	Chance Response at Project Proposal Submission
Community Open House Event	Vuntut Gwitchin First Nation Residents of Old Crow	13-Sep-2023	Shared the community of Old Crow would need job training with financial support.	Chance responded that job-related training would be provided for Project employees.	Comment was addressed at the time it was shared. See **Section 11** of the Project Proposal for more information on potential Project-related effects on and mitigation measures for employment and economy.
Socio-Economics					
Meeting	Vuntut Gwitchin First Nation	03-Sep-2020	Asked what process Chance will use to protect oral history. Asked what the timeline is for collecting data on wildlife, oral history, and interviewing people in the area. Stated they would like to see a review of oral history.	Chance acknowledged and recorded the comment. Chance stated they are relying on existing information and any data collected to date.	Comment was addressed at the time it was shared. Chance sent Vuntut Gwitchin First Nation a Draft Collaboration Plan in November 2023 outlining proposed consultation and engagement activities to support the Project Proposal assessment process for the Eagle Plains Exploration Project up to February 2024 for Vuntut Gwitchin First Nation's review and comment. This document included information on socio-economic interview timeline. Chance sent Vuntut Gwitchin First Nation a list of identified secondary sources of Traditional Knowledge for Vuntut Gwitchin First Nation's review, comment, and permission for use. The secondary sources were selected based on Chance's understanding that they included Traditional Knowledge relevant to the Project. Chance invited Vuntut Gwitchin First Nation to share any additional Traditional Knowledge sources that may not be listed to help inform the development of the socio-economic assessment and Project Proposal. Chance requested Vuntut Gwitchin First Nation's feedback on any protocols or guidance for the use of Traditional

Interaction Type	Respondent	Date	Comment / Issue	Chance Response at the Time of Engagement	Chance Response at Project Proposal Submission
					Knowledge to inform the socio-economic assessment. Chance hosted topic-specific focus group discussions to share potential Project effects information with and obtain feedback on mitigation measures from Vuntut Gwitchin First Nation and residents of Old Crow on December 6, 2023.
Letter	Vuntut Gwitchin First Nation	05-Aug-2022	Commented previous negative effects of oil and gas exploration to Vuntut Gwitchin First Nation's livelihood.	Chance acknowledged and recorded the comment.	Chance acknowledges the negative effects on Vuntut Gwitchin First Nations's livelihood by previous exploration activities. Chance is committed to reducing and/or eliminating any similar potential negative effects resulting from its Project. It will follow all relevant legislation and policies to reduce the potential for negative effects.
Meeting	Vuntut Gwitchin First Nation	03-Sep-2020	Identified a gap with regards to the assessment of potential Project effects on Vuntut Gwitchin First Nation harvesting rights.	Chance acknowledged and recorded the comment.	Chance is committed to reducing, eliminating, and/or mitigating any potentially negative effects on affected First Nations' harvesting rights. It has undergone a rigorous effects assessment, as seen within the Project Proposal submitted to YESAB's EC. Chance is open to future discussions with potentially affected First Nations regarding concerns surrounding harvesting rights and other topics.
Cumulative Effects					
Meeting	Vuntut Gwitchin First Nation	04-Aug-2023	Requested information about the Project's approach to cumulative effects.	Chance acknowledged and recorded the comment. Chance stated that it had conducted a linear features assessment to assess regrowth of linear features.	See **Section 3** of the Project Proposal for more information regarding cumulative effects methods.

Interaction Type	Respondent	Date	Comment / Issue	Chance Response at the Time of Engagement	Chance Response at Project Proposal Submission
				Chance identified that this and other such information will feed into the cumulative effects for the Project.	
Mitigations and Monitoring					
Meeting	Vuntut Gwitchin First Nation	03-Sep-2020	Requested access to Chance's monitoring protocols. Inquired about possible mitigation measures.	Chance acknowledged and recorded the comment. Chance stated that there will be very limited traffic and most of the traffic will be wildlife monitors. Chance stated there will be a team above the monitors that they will report to (e.g., wildlife biologists, Vuntut Gwitchin First Nation staff). The team will be used to discuss and provide advice to put together an effective site-specific mitigation measure.	Chance is committed to controlling and restricting public use of its access roads. Chance recognizes this is a concern and will engage potentially affected First Nations further on this issue. Chance will limit traffic on the winter access to authorized personnel. Traffic will include approximately 8 to 9 light-weight service trucks daily (for supplies and personnel), 1 to 2 water trucks, and 1 fuel truck as frequently as exploration activities dictate (see **Section 11**).
Community Open House Event	Vuntut Gwitchin First Nation Residents of Old Crow	26-May-2022	Vuntut Gwitchin First Nation expressed concern about spill monitoring, reporting, and mediation.	Chance acknowledged and recorded the comment.	Chance to list the fluids and materials necessary. Personnel trained in spill response will be onsite for the duration of the Project. In addition to spill response and cleanup, the spill response plan will include details on reporting requirements. More information about the type of materials used for the flow tests is available in **Section 1** of the Project Proposal. Chance will establish and enforce procedures to prevent unintended fluid release into the environment. Furthermore, an Emergency Spill and Response Plan and

Interaction Type	Respondent	Date	Comment / Issue	Chance Response at the Time of Engagement	Chance Response at Project Proposal Submission
					an Environmental Protection Plan will be devised, encompassing specifics on environmental monitoring and internal adherence to spill prevention and response measures. Chance will develop and implement procedures to prevent the inadvertent release of oil to the ground or waterways. See **Section 1 and 12** of the Project Proposal for more information.
Community Open House Event	Vuntut Gwitchin First Nation Residents of Old Crow	13-Sep-2022	Recommended the role of monitoring, research, and academic involvement in the area.	Chance shared monitoring would be conducted throughout the Project and offered to share Project-related studies with interested parties to support research and academic studies in the area.	Comment was addressed at the time it was shared. See **Sections 11 and 12** of the Project Proposal for more information regarding monitoring.
Community Open House Event	Vuntut Gwitchin First Nation Residents of Old Crow	06-Dec-2023	Participants observed that no progressive reclamation had occurred in the last 3 years. Vuntut Gwitchin First Nation thought an environmental firm typically completes this work. Perhaps there is an economic opportunity here for Vuntut Gwitchin Government.	Monitoring programs and follow-up monitoring will be in place. Follow-up meetings will occur to demonstrate work completed. Chance is required to set money aside for reclamation.	Chance recognizes the concern surrounding closure activities and reclamation. Chance is committed to following all applicable legislation and policies, including undertaking reclamation activities after Project exploration activities have been completed. Monitoring programs and follow-up monitoring will be in place. Follow-up meetings will occur to demonstrate work completed. Chance is required to set money aside for reclamation. For more information on clearing activities and reclamation plans, see **Sections 1 and 12** of the Project Proposal.
Community Open	Vuntut Gwitchin First Nation	O6-Dec-2023	Expressed interest in a wildlife monitoring program.	There will be a wildlife monitoring program that employs locals. Chance	Comment was addressed at the time it was shared.

Interaction Type	Respondent	Date	Comment / Issue	Chance Response at the Time of Engagement	Chance Response at Project Proposal Submission
House Event	Residents of Old Crow			acknowledged and recorded the comment.	See **Section 8, 11 and 12** of the Project Proposal for more information regarding monitoring.
YESAB Process					
Community Open House Event Meeting	Vuntut Gwitchin First Nation Residents of Old Crow Vuntut Gwitchin First Nation	26-May-2022 26-Jan-2023 06-Dec-2023	Requested clarification about the YESAB process, the EC, and status of engagement. Expressed concern about the YESAB process. Inquired about the assessment Process.	Chance acknowledged and recorded the comment and concern.	Chance presented an overview of the YESAB EC Screening Process on October 13, 2023 during a meeting with Vuntut Gwitchin First Nation Deputy Councillor, technical advisors and staff. The same information was shared at a community open house event with Vuntut Gwitchin First Nation Citizens and residents of Old Crow on September 13, 2023.
Community Open House Event	Vuntut Gwitchin First Nation Residents of Old Crow	13-Sep-2023	Requested more information on the YESAB environmental assessment process for the Project.	Chance prepared and distributed a 2-page handout at a December 2023 community event in Old Crow to share Project information, a description of the YESAB assessment process, studies completed by Chance, the Project assessment process timeline, and key First Nation Project feedback and Chance's responses to shared feedback.	Comment was addressed at the time it was shared.
Community Open House Event	Vuntut Gwitchin First Nation Residents of Old Crow	13-Sep-2023	Noted the north is presently predominately reliable on oil and gas and believe its time for Vuntut Gwitchin First Nation to get involved in the Project and make recommendations to YESAB.	Chance shared that the Project Proposal submitted to YESAB will be available for public review and comment. YESAB is required to review recommendations made about the Project through the public review and comment period.	Comment was addressed at the time it was shared.

Interaction Type	Respondent	Date	Comment / Issue	Chance Response at the Time of Engagement	Chance Response at Project Proposal Submission
Community Open House Event	Vuntut Gwitchin First Nation Residents of Old Crow	13-Sep-2023	Stated Chance had done what they can to give information on the Project and that Vuntut Gwitchin First Nation had the ability to make recommendations to YESAB and the Government of Yukon.	Chance acknowledged the comment.	Comment was addressed at the time it was shared.
Reclamation and Remediation					
Meeting	Vuntut Gwitchin First Nation	03-Nov-2020	Questioned whether successful flow testing of subsequent resource development can be seen as reasonable in the foreseeable future.	Chance acknowledged and recorded the comment. Chance stated that it will be difficult to consider what would be there in the future.	Comment was addressed at the time it was shared.
Letter	Vuntut Gwitchin First Nation	05-Aug-2022	Recognized the feasibility of oil and gas production is diminished with a high probability of infrastructure becoming stranded assets.	Chance acknowledged and recorded the comment.	Chance recognizes the concern surrounding closure activities and reclamation. Chance is committed to following all applicable legislation and policies, including undertaking reclamation activities after Project exploration activities have been completed. Monitoring programs and follow-up monitoring will be in place. Follow-up meetings will occur to demonstrate work completed. Chance is required to set money aside for reclamation. For more information on clearing activities and reclamation plans, see **Sections 1 and 12** of the Project Proposal.
Community Open House Event	Vuntut Gwitchin First Nation Residents of Old Crow	06-Dec-2023	Inquired about who would lead the reclamation.	Chance is doing the reclamation. The Project should not need extensive reclamation. Natural regeneration will occur. If any spills occurred Chance	Chance recognizes the concern surrounding closure activities and reclamation. Chance is committed to following all applicable legislation and policies, including undertaking reclamation

Interaction Type	Respondent	Date	Comment / Issue	Chance Response at the Time of Engagement	Chance Response at Project Proposal Submission
				would be responsible for reclamation. The main effort would be dismantling the camp.	activities after Project exploration activities have been completed. Monitoring programs and follow-up monitoring will be in place. Follow-up meetings will occur to demonstrate work completed. Chance is required to set money aside for reclamation. For more information on clearing activities and reclamation plans, see **Section 1 and 12** of the Project Proposal.
Heritage Resources					
Community Open House Event	Vuntut Gwitchin First Nation	06-Dec-23	Inquired about whether a heritage site is the same as an unmarked burial site.	Archaeological finds are turned over to the Government of Yukon Heritage Resource Unit. Chance responded that no burials have been discovered. Studies have only uncovered tools. Chance explained that soil in the Project footprint is not ideal for preserving organic material. If any heritage resources, archaeological, or paleontological items are discovered, Chance will follow all legislation.	If heritage resources including human remains are encountered within the Project footprint, all work in the vicinity will stop immediately and First Nations, the Government of Yukon Heritage Resource Unit will be contacted for guidance on how to proceed. The RCMP would also be contacted if human remains were encountered. This consultation will be guided by the principles laid out in the *Guidelines Respecting the Discovery of Human Remains and First Nation Burial Sites* in the Yukon document published by the Government of Yukon's Heritage Resource Unit. Chance will prepare a *Chance Find Procedure* which will apply during all Project activities. Chance is committed to discussing and working with potentially affected First Nations to support their involvement in future heritage resources studies. See **Section 10** for information on Project-related effects to and mitigation measures for heritage resources.

Interaction Type	Respondent	Date	Comment / Issue	Chance Response at the Time of Engagement	Chance Response at Project Proposal Submission
Community Open House Event	Vuntut Gwitchin First Nation	06-Dec-2023	Participants wanted to know what Chance has found at the site thus far and what is done with the artifacts. Inquired about how Chance employees would approach an archaeological find. Participants wanted to see a copy of the Chance "Find Procedure".	Archaeological finds are turned over to the Government of Yukon Heritage Resource Unit. Chance responded that no burials have been discovered. Studies have only uncovered tools. Chance explained that soil in the Project footprint is not ideal for preserving organic material. If any heritage resources, archaeological, or paleontological items are discovered, Chance will follow all legislation.	Employees would create a 30 m buffer area around archaeological and heritage sites to protect and avoid the areas. If a drill site overlaps with an archaeological site, the Project will implement measures to remove all the artifacts on site. This will be conducted in compliance with Federal, Provincial, First Nation, and industry best practices and standards. The *Chance Find Procedure* is being developed by the Project once it is implemented the First Nations will be notified. Chance is committed to discussing and working with potentially affected First Nations to support their involvement in future heritage resources studies. See **Section 10** for information on Project-related effects to and mitigation measures for heritage resources.
Community Open House Event	Vuntut Gwitchin First Nation Residents of Old Crow	06-Dec-2023	Citizens encouraged Chance to work with the Vuntut Gwitchin Government Natural Resource department. Vuntut Gwitchin First Nation noted that they have a lot of information that can inform Chance's work.	Chance thanked the attendee for their comment and noted they would continue to engage Vuntut Gwitchin Government on the Project including sharing heritage resources information. Chance planned a technical working group with government and technical advisor representatives from all potentially affected First Nations and Government of Yukon to discuss the Project's archaeological and	Chance will work with potentially affected First Nations to support their involvement in future heritage resources studies. See **Section 10** for information on Project-related effects to and mitigation measures for heritage resources.

Interaction Type	Respondent	Date	Comment / Issue	Chance Response at the Time of Engagement	Chance Response at Project Proposal Submission
				heritage resource studies on January 16, 2024.	
Vegetation					
Community Open House Event	Vuntut Gwitchin First Nation Residents of Old Crow	06-Dec-2023	Asked if Chance could give examples of lichen protection.	The Chance Project Team shared that conducting Project activities in the winter will reduce potential Project-related effects to lichen. The Chance Project Team added that lichen is also protected because newer seismic technology will not require that vegetation be cut all the way to the ground. Added that lichen is also protected when winter access roads are reused.	Comment was addressed at the time it was shared. See **Section 7** for information on Project-related effects to and mitigation measures for vegetation.
Other					
Meeting	Vuntut Gwitchin First Nation	26-Jan-2023	Stated that it is critical that Chance consider Indigenous Knowledge within its Project Proposal to YESAB.	Chance acknowledged and recorded the comment.	Chance will consult and engage with potentially affected First Nations in a respectful and appropriate manner, in accordance with First Nation protocols and preferences, and *YESAA* requirements. Chance sent Vuntut Gwitchin First Nation a list of identified secondary sources of Traditional Knowledge for Vuntut Gwitchin First Nation's review, comment, and permission for use. The secondary sources were selected based on Chance's understanding that they included Traditional Knowledge relevant to the Project footprint. Chance invited Vuntut Gwitchin First Nation to share any additional Traditional Knowledge sources that may not be listed to help inform the development of the socio-

Interaction Type	Respondent	Date	Comment / Issue	Chance Response at the Time of Engagement	Chance Response at Project Proposal Submission
					economic assessment and Project Proposal. Chance requested Vuntut Gwitchin First Nation's feedback on any protocols or guidance for the use of Traditional Knowledge to inform the socio-economic assessment. Chance hosted topic-specific focus group discissions to share potential Project effects information with and obtain feedback on mitigation measures from Vuntut Gwitchin First Nation Citizens and residents of Old Crow on December 6, 2023.
Community Open House Event	Vuntut Gwitchin First Nation Residents of Old Crow	06-Dec-2023	Inquired about Old Crow transitioning to cleaner energy sources.	The Chance Project Team said royalties from a future extraction project could be used by Vuntut Gwitchin Government to support the transition to more sustainable energy sources.	Comment was addressed at the time it was shared.

2.9.9 Ongoing Consultation and Engagement

Chance will continue to consult and engage Vuntut Gwitchin First Nation and residents of Old Crow following submission of the Project. Chance will refine the Program in response to feedback from Vuntut Gwitchin First Nation during future Project phases, as needed. Planned ongoing consultation and engagement activities include (but are not limited to):

- Project communications (e.g., updates regarding schedule, permitting, monitoring activities, incorporation of Indigenous Knowledge to Project plans, and capacity funding);
- meetings to discuss Project-related effects, issues, and interests;
- opportunities to review and provide comment on Project plans and materials; and,
- opportunities to develop Project-related mitigation measures.

2.10 CONSULTATION AND ENGAGEMENT WITH TR'ONDËK HWËCH'IN AND RESIDENTS OF DAWSON CITY

Section 2.10 outlines consultation and engagement activities with Tr'ondëk Hwëch'in. Information on Project notification, consultation and engagement planning, methods, and activities, agreements, issues, interests, and feedback shared through consultation and engagement activities are described in **Sections 2.10.1** - **2.10.9**.

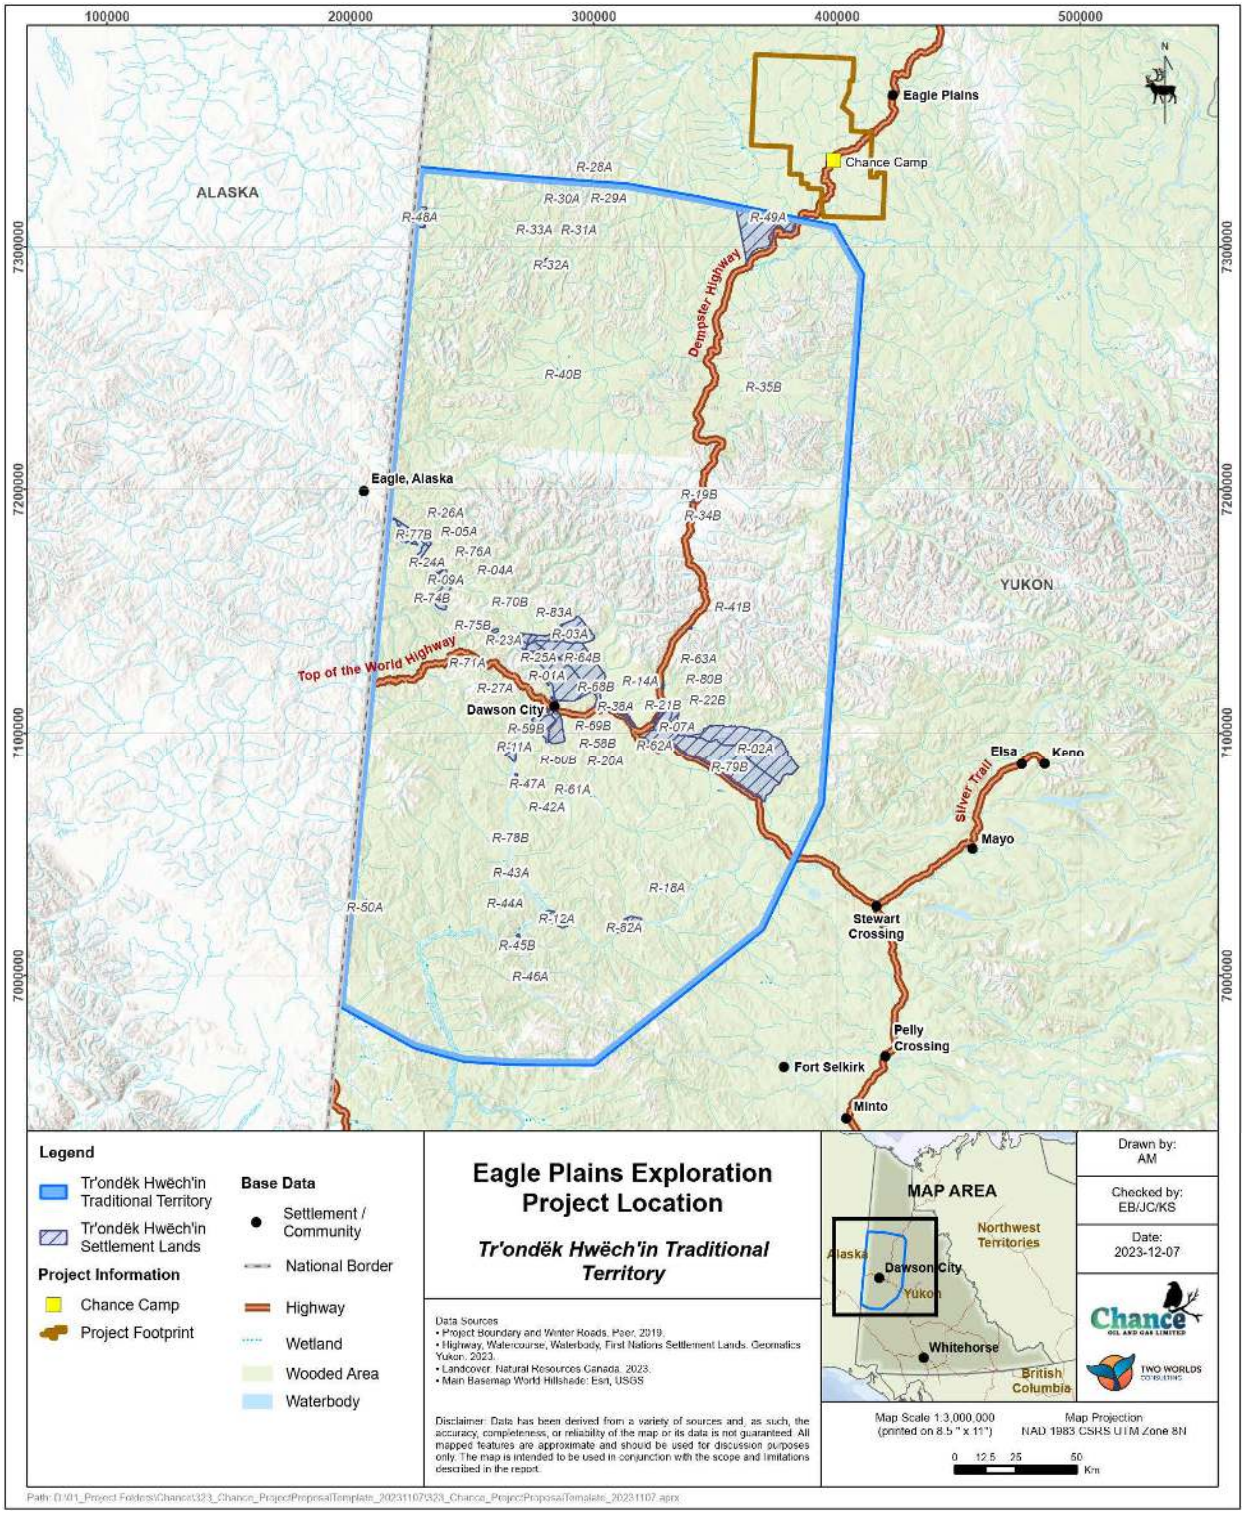
2.10.1 Community Profile

2.10.1.1 Tr'ondëk Hwëch'in

> "The name, Tr'ondëk Hwëch'in, tells the story of our ancestral occupation of the ancient site located at the mouth of present day Klondike on the left limit. Tr'o means hammer rock used to drive the salmon weir stakes into the mouth of the river, ndëk is the "river" part and Hwëch'in means the "people". Liberally translated, it means: the people who lived at the mouth of the Klondike. (Gerald Isaac, February 1999)" (Tr'ondëk Hwëch'in n.d.)

Tr'ondëk Hwëch'in have traced lineage to the area now known as Dawson City, Yukon dating back 11,000 years (Tr'ondëk Hwëch'in, n.d.-a). Since then, Tr'ondëk Hwëch'in Peoples worked to strike a balance between their traditional lifestyle and the ways of the newcomers (Tr'ondëk Hwëch'in, n.d.-b).

As of September 2023, Tr'ondëk Hwëch'in have a registered population of 961 Citizens (Government of Canada 2023a). Tr'ondëk Hwëch'in holds a total of 2,598.51 km^2 of land, with 1,553.99 km^2 of Category A Lands, 1,036 km^2 of Category B Lands, and 8.52 km^2 is other allocated land (Fred 2006). **Map 2-5** shows Tr'ondëk Hwëch'in's Traditional Territory as well as the settlement land agreed to under the *Tr'ondëk Hwëch'in Final Agreement*.



Map 2-5: Tr'ondëk Hwëch'in Traditional Territory

The *Tr'ondëk Hwëch'in Final Agreement* was signed in 1998 and today Tr'ondëk Hwëch'in exercise self-governance (Council of Yukon First Nations 1993). The *Tr'ondëk Hwëch'in Final Agreement* builds off the UFA and lists specific provisions pertaining to consultation, land and resource use, settlement land, self-governance, and taxation. The *Tr'ondëk Hwëch'in Final Agreement* ensured that the Tr'ondëk Hwëch'in people could govern themselves and protect their land and rights (Tr'ondëk Hwëch'in, n.d.-b). The Tr'ondëk Hwëch'in governance structure includes he Hähkè, Deputy Chief, and three councillors. The current Tr'ondëk Hwëch'in leadership is composed of: Hähkè Darren Taylor, Deputy Chief Erin McQuaig, and Councillors Kylie Van Every, Kyrie Nagano, and Ryan Peterson. The Tr'ondëk Hwëch'in governance structure is shown in **Figure 2-6**.

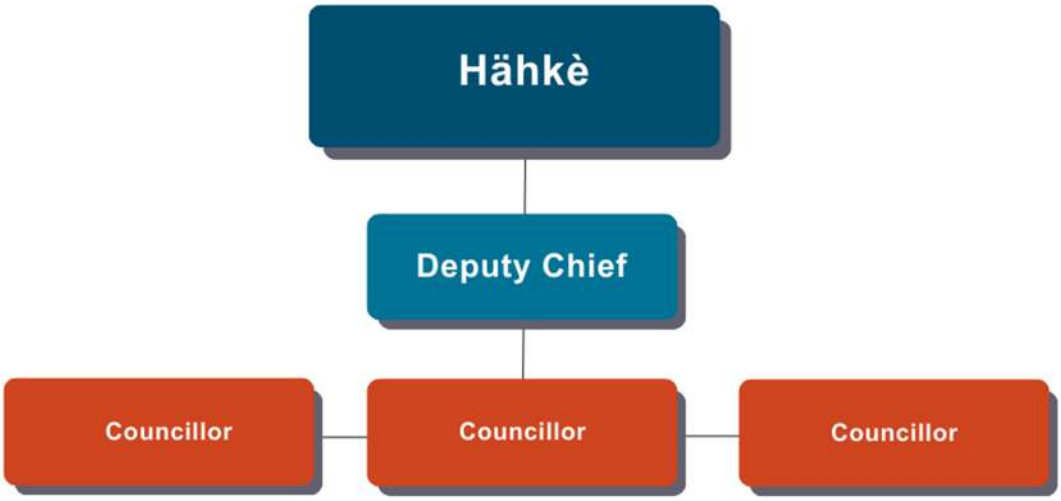


Figure 2-6. Tr'ondëk Hwëch'in Governance Structure

> To preserve our heritage and ensure a strong future, the Tr'ondëk Hwëch'in invest in promoting our Hän language, learning traditional skills from Elders, and engaging youth. Initiatives like the Moosehide Gatherings, Dänojà Zho Cultural Centre, Tr'ochëk National Historic site, and the return of our entrusted songs
>
> demonstrate our commitment to cultural preservation and pride in our ancestry (Tr'ondëk Hwëch'in n.d.).

The Tr'ondëk Hwëch'in's First Nation language is Hän, which is an important part of the community's heritage and culture:

2.10.1.2 Dawson City

Dawson City is located approximately 530 km north of Whitehorse, on the east bank of the Yukon River, at the confluence of the Klondike River at the heart of the Tr'ondëk Hwëch'in Traditional Territory. Dawson City was founded in 1896 by Joseph Ladue and named in January 1897 after Canadian geologist George M. Dawson. Dawson City was Yukon's capital from 1898 until 1952, after which it was moved to Whitehorse (Klondike Visitors Association, n.d.; Greener Pasture, n.d.; City of Dawson, n.d.). As of 2021, Dawson's

registered population was 1,577 people, making it the second-largest community in the Yukon (Government of Canada 2022).

Dawson City Municipal Government is comprised of one mayor and four councillors, each elected for a 4-year term with the most recent election held in October 2021 (City of Dawson, n.d.).

Dawson City has a thriving economy based in the mining, tourism, and culture sectors. As of 2021, the industries with the largest proportion of the workforce were public administration, construction, and educational services (City of Dawson, n.d.; Government of Canada 2022).

Dawson City has two healthcare facilities: a hospital and a health centre. Dawson City Community Hospital is the second-largest hospital in the Yukon, and offers 24/7 emergency care, inpatient and ambulatory care, X-ray, laboratory services, and general ultrasound. Dawson City Health Centre offers treatment programs and activities, including visiting doctor clinics, referrals, immunization clinics, prenatal classes, postnatal care, nursing and residential care, and school health clinics (Government of Yukon 2018). The Dawson City Health Centre is attached to the Dawson City Community Hospital.

Dawson's only school is the Robert Service School, which offers enrolment from Kindergarten to Grade 12. Dawson also has a Yukon University campus that offers a variety of certificates, diplomas, degrees, vocational, and upgrading programs and courses targeted to meet the employment needs of the mining, culture, and tourism sectors (Government of Yukon 2022; Yukon University, n.d.).

Please refer to **Section 11** for more socio-economic information on Dawson City.

2.10.2 Project Notification

Chance initiated engagement with Tr'ondëk Hwëch'in on September 26, 2018. Chance sent a letter (**Appendix 2-D Tr'ondëk Hwëch'in and Residents of Dawson City Consultation and Engagement Records**) to Tr'ondëk Hwëch'in about the *Tr'ondëk Hwëch'in and Chance Oil and Gas Communications and Engagement Plan* (**Appendix 2-D**) and next steps to develop a partnership with Tr'ondëk Hwëch'in.

Chance initiated consultation and engagement with residents of Dawson City at a community open house event on June 18, 2014.

2.10.3 Consultation and Engagement Planning

Chance has and will continue to consult Tr'ondëk Hwëch'in and residents of Dawson City who may be potentially affected by the Project to better understand potential Project-related effects on their First Nation, Citizens, and community. Chance recognizes Tr'ondëk Hwëch'in sits on the North Yukon Oil and Gas International Forum and Porcupine Caribou Management Board, both entities Chance has engaged about the Project.

Chance developed an Tr'ondëk Hwëch'in and Chance Oil and Gas Limited Engagement and Communication Plan (**Appendix 2-D**) outlining a proposed engagement approach with Tr'ondëk Hwëch'in. The Tr'ondëk Hwëch'in and Chance Oil and Gas Limited Engagement and Communication Plan included information on communication pathways, meeting process, engagement documentation, and adaptive management. Tr'ondëk Hwëch'in sent the Tr'ondëk Hwëch'in and Chance Oil and Gas Limited Engagement and Communication Plan to the Government of Yukon on August 28, 2018.

2.10.4 Consultation and Engagement Methods

Engagement methods with Tr'ondëk Hwëch'in up to December 20, 2023 have included

- meetings (virtual and in-person);
- letters;
- correspondence via phone call, text message, and email; and,
- information sharing (e.g., sharing Project documents for review and comment).
- Chance will adjust consultation and engagement methods in response to feedback from Tr'ondëk Hwëch'in throughout the life of the Project.

2.10.5 Consultation and Engagement Activities

Table 2-8 outlines engagement activities undertaken with Tr'ondëk Hwëch'in and residents of Dawson City up to December 20, 2023.

Engagement materials such as presentations and handouts shared with Tr'ondëk Hwëch'in and residents of Dawson City have been compiled in **Appendix 2-D** of this Project Proposal. Where appendices were unavailable for compilation, **Table 2-8** indicates as such with an asterisk.

Table 2-8. Key Consultation and Engagement Activities with Tr'ondëk Hwëch'in

Recipient or Participant	Engagement Activity	Date	Description of Chance Consultation and Engagement
Tr'ondëk Hwëch'in	Correspondence via phone call, text message, and email	Ongoing	Coordinating engagement activities and sharing Project information.
Chance Tr'ondëk Hwëch'in Residents of Dawson City	Community Open House Event	18-Jun-2014	Held an open house in Dawson City at the Yukon Order of Pioneers Hall. The open house included a formal presentation by Chance followed by a question-and-answer period (**Appendix 2-D**)*.
Tr'ondëk Hwëch'in	Letter	01-Dec-2017	Provided information on the communication and engagement plan that Chance wished to develop in partnership with Tr'ondëk Hwëch'in (**Appendix 2-D**)*.
Tr'ondëk Hwëch'in	Letter	27-Feb-2018	Followed up to request a meeting with Tr'ondëk Hwëch'in on developing a communication and engagement plan (**Appendix 2-D**)*.
Chance Tr'ondëk Hwëch'in	Phone Call	15-Mar-2018	Had a conversation with the Chief of Tr'ondëk Hwëch'in regarding letters and follow-up. Chance suggested a meeting in April (**Appendix 2-D**)*.
Chance Tr'ondëk Hwëch'in	Meeting	10-Apr-2018	Discussed relationship-building with Tr'ondëk Hwëch'in and collaboration on a *Communications and Engagement Plan* per Government of Yukon's Order in Council 2017/037 (**Appendix 2-D**)*.
Tr'ondëk Hwëch'in	Letter	08-May-2018	Notified Tr'ondëk Hwëch'in about Chance's upcoming submission of a request to extend the tenure of the exploration permits (#0012-117) (**Appendix 2-D**)*.
Tr'ondëk Hwëch'in	Document sharing for review and comment	17-May-2018	Shared the Tr'ondëk Hwëch'in and Chance Oil and Gas Limited Engagement and Communication Plan (Draft) (**Appendix 2-D**)*.
Tr'ondëk Hwëch'in	Document sharing for records	23-Jul-2018	Shared the Tr'ondëk Hwëch'in Traditional Territory shapefiles (**Appendix 2-D**)*.
Tr'ondëk Hwëch'in	Meeting	23-Jul-2018	Discussed revisions to the Tr'ondëk Hwëch'in and Chance Oil and Gas Limited Engagement and Communication Plan (**Appendix 2-D**)*.
Tr'ondëk Hwëch'in	Letter	26-Jul-2018	Updated Chief and Council on the Tr'ondëk Hwëch'in and Chance Oil and Gas Limited Engagement and Communication Plan (**Appendix 2-D**).
Tr'ondëk Hwëch'in	Document sharing for review and comment	17-Oct-2018	Shared the Draft *Confidentiality Agreement* (**Appendix 2-D**)*.

Recipient or Participant	Engagement Activity	Date	Description of Chance Consultation and Engagement
Chance Tr'ondëk Hwëch'in	Meeting	23-Oct-2018	Discussed implementation of the *Tr'ondëk Hwëch'in and Chance Oil and Gas Limited Engagement and Communication Plan* that was submitted to Government of Yukon on August 28, 2018 (**Appendix 2-D**).
Chance Tr'ondëk Hwëch'in	Meeting	23-Nov-2018	Discussed capacity funding and a meeting with Government of Yukon, YESAB, and potentially affected First Nations (**Appendix 2-D**).
Tr'ondëk Hwëch'in	Document sharing for signature	04-Dec-2018	Provided the *Capacity Funding* letter (Final Version) for signing (**Appendix 2-D**)*.
Tr'ondëk Hwëch'in	Document sharing for records	24-Jan-2019	Sent the *Confidentiality Agreement* dated January 22, 2019 (**Appendix 2-D**).
Tr'ondëk Hwëch'in	Letter	27-Mar-2019	Notified Tr'ondëk Hwëch'in of a request to extend tenure on Exploration Permits (#0006-0011 and #0019) (**Appendix 2-D**).
Tr'ondëk Hwëch'in	Document sharing for records	07-Jun-2019	Shared the *Draft Project Description* (Version 1) (**Appendix 2-D**).
Chance Tr'ondëk Hwëch'in	Meeting	11-Jun-2019	Presented the *Draft Project Description* (Version 1) Discussed next steps in the YESAB EC process, annual reporting requirements, and capacity funding (**Appendix 2-D**).
Tr'ondëk Hwëch'in	Letter	14-Jun-2019	Shared a notice letter with Tr'ondëk Hwëch'in stating EDI would be conducting fish and environmental studies scheduled from July 1 to July 10, 2019 pending authorization from the Fisheries and Oceans Canada (DFO) license (**Appendix 2-D**).
Tr'ondëk Hwëch'in	Document sharing for records	25-Jun-2019	Shared the *Draft Project Description* (Version 1) (**Appendix 2-D**).
Tr'ondëk Hwëch'in	Document sharing for records	25-Jun-2019	Shared the Community Consultation Program (Proposed Activity Alignment) (**Appendix 2-D**).
Tr'ondëk Hwëch'in	Document sharing for records	31-Jul-2019	Shared the Annual 2019 Report on the Implementation of Tr'ondëk Hwëch'in and Chance Oil and Gas Limited Engagement and Communication Plan (Draft) (**Appendix 2-D**).
Chance Tr'ondëk Hwëch'in	Meeting	12-Aug-2019	Met with Tr'ondëk Hwëch'in to provide Project updates, capacity funding, and a Cooperation Agreement (**Appendix 2-D**).
Chance Tr'ondëk Hwëch'in	Virtual meeting	17-Jun-2020	Provided an overview of the proposed Eagle Plain Well Maintenance Project and provided an opportunity for Tr'ondëk Hwëch'in to ask questions and/or provide feedback (**Appendix 2-D**).

Recipient or Participant	Engagement Activity	Date	Description of Chance Consultation and Engagement
Tr'ondëk Hwëch'in	Document sharing for review and comment	13-Jul-2020	Shared the Annual 2020 Report on the Implementation of Tr'ondëk Hwëch'in and Chance Oil and Gas Limited Engagement and Communication Plan (Draft) (**Appendix 2-D**).
Tr'ondëk Hwëch'in	Document sharing for records	24-Jul-2020	Shared the *Project Proposal* (Version 1) (**Appendix 2-D**).
Tr'ondëk Hwëch'in	Document sharing for records	24-Jul-2020	Shared the Emergency Spill Response Plan (**Appendix 2-D**).
Tr'ondëk Hwëch'in	Document sharing for records	28-Mar-2021	Shared the Methods of Hydraulic Fracturing (**Appendix 2-D**).
Tr'ondëk Hwëch'in	Meeting	27-Apr-2021	Presented a draft *Project Description* (Version 1). Chance provided information and updates regarding baseline studies and discussed consultation and engagement next steps (**Appendix 2-D**).
Tr'ondëk Hwëch'in	Document sharing for review and comment	12-May-2021	Shared Chance's 2021 Engagement Schedule (**Appendix 2-D**).
First Nation of Na-Cho Nyäk Dun Tr'ondëk Hwëch'in	Document sharing for records	18-May-2021	Shared the Chance Eagle Plains Exploration Project: Baseline Information on Terrain Permafrost and Suitability Maps (**Appendix 2-D**).
Chance Tr'ondëk Hwëch'in	Virtual meeting	08-Jun-2021	Discussed permafrost baseline information, consultation and engagement preferences, planning, and upcoming reports (**Appendix 2-D**).
Tr'ondëk Hwëch'in	Document sharing for review and comment	16-Jul-2021	Shared the Draft Annual 2021 Report on the Implementation of Tr'ondëk Hwëch'in and Chance Oil and Gas Limited Engagement and Communication Plan (**Appendix 2-D**).
First Nation of Na-Cho Nyäk Dun Vuntut Gwitchin First Nation Gwich'in Tribal Council Tr'ondëk Hwëch'in	Document sharing for records	17-Dec-2021	Shared a letter to the Government of Yukon, Land Tenure Extension Request for Exploration Permits 0008-0017, 0019 and 0020 ("Permits") (**Appendix 2-D**).
Chance	Document sharing for review and comment	29-Jul-2022	Sent Chance a signed copy of the 2022 Annual Report on the Implementation of Tr'ondëk Hwëch'in and Chance Oil and Gas Limited Engagement and Communication Plan (**Appendix 2-D**).
Tr'ondëk Hwëch'in	Letter	27-Jun-2023	Updated the newly elected Chief about the Project (**Appendix 2-D**).

Recipient or Participant	Engagement Activity	Date	Description of Chance Consultation and Engagement
Chance Technical advisor on behalf of Tr'ondëk Hwëch'in and First Nation of Na-Cho Nyäk Dun	Meeting	03-Aug-2023	Discussed the Project, consultation and engagement activities, socio-economic secondary and primary data collection, and well abandonment (**Appendix 2-D**).
Tr'ondëk Hwëch'in	Document sharing for records	05-Sep-2023	Shared the Draft Project Overview Video (**Appendix 2-D**).
Chance Potentially affected First Nations Government of Canada YESAB Government of Yukon Tr'ondëk Hwëch'in	Meeting	13-Oct-2023	Discussed the Project's assessment process including capacity funding and possible efficiencies through a coordinated approach (e.g., sharing consultants to support potentially affected First Nations' review of the Project Proposal) (**Appendix 2-D**).
Tr'ondëk Hwëch'in	Letter	22-Nov-2023	Requested feedback from Tr'ondëk Hwëch'in First Nation regarding interest in being consulted about the draft Project Proposal (**Appendix 2-D**).
* = Appendices not available at the time this section was drafted.			

2.10.6 Agreements

Chance and Tr'ondëk Hwëch'in have not discussed any formal agreement for the Project to date.

2.10.7 Records Management

Appendix 2-D includes a record of contact documenting all consultation and engagement activities including emails, phone calls, text messages, letters, meetings, and events between Chance and Tr'ondëk Hwëch'in to up to December 20, 2023, and a record of contact documents all consultation and engagement activities with residents of Dawson City up to December 20, 2023.

2.10.8 Engagement Feedback (Effects, Issues, and Interests)

Chance sought to obtain feedback from potentially affected First Nations and residents of communities through Project engagement activities. **Table 2-9** presents effects, issues, and interests shared by Tr'ondëk Hwëch'in with Chance up to December 20, 2023.

Table 2-9. Tr'ondëk Hwëch'in Key Issues and Consultation and Engagement Feedback

Interaction Type	Respondent	Date	Comment / Issue	Chance's Response at the Time of Engagement	Chance's Response at Project Proposal Submission
Project Design					
Meeting	Tr'ondëk Hwëch'in	12-Aug-2019	Expressed concern for the *Resource Access Roads Framework's* timeline to completion (Government of Yukon, n.d.). Concerned about the negative effects of increased road access.	Chance acknowledged and recorded the comment. Chance expressed a desire for access regulations to be completed by Government of Yukon. It recognized that such legislation would address public access issues to the Project footprint.	Chance is committed to controlling and restricting public use of its winter access roads. Chance recognizes this is a concern and will engage potentially affected First Nations further on this issue. Chance will limit traffic on the winter access to authorized personnel. Chance staff hired as wildlife monitors and security personnel will monitor access to the winter access roads. Traffic will include approximately 8 to 9 light-weight service trucks daily (for supplies and personnel), 1 to 2 water trucks, and 1 fuel truck as frequently as exploration activities dictate (see **Section 1**). Traffic is expected to be higher during rig moves, delivery of casing, and other operational events. These types of events will be periodic rather than steady.
Consultation and Engagement Process					
Meeting	Tr'ondëk Hwëch'in	10-Oct-2018	Expressed interest in both parties developing a capacity funding agreement.	Chance acknowledged and recorded the comment.	Chance to address details and follow-up to this capacity funding agreement.
Meeting	Tr'ondëk Hwëch'in	08-Jun-2021	Expressed a desire for a positive relationship between the parties and opening communication channels. Discussed the importance of Tr'ondëk Hwëch'in, Vuntut Gwitchin First Nation, First Nation of Na-	Chance acknowledged and recorded the comment. Chance responded that it wishes to foster a good working relationship with all potentially affected First Nations and will continue to actively work on this.	Chance is committed to building positive and open relationships with all potentially affected First Nations. Chance will consult and engage with potentially affected First Nations in a respectful manner and in accordance with First Nation protocols and preferences, and *YESAA* requirements.

Interaction Type	Respondent	Date	Comment / Issue	Chance's Response at the Time of Engagement	Chance's Response at Project Proposal Submission
			Cho Nyäk Dun working together.		
Wildlife and Wildlife Habitat					
Meeting	Tr'ondëk Hwëch'in	03-Aug-2023	Expressed concerns for seismic effects on predator-prey relationships.	Chance acknowledged and recorded the comment. Chance described and shared the *Linear Features Study* conducted to assess and support mitigation decisions related to this concern.	Chance undertook a study on linear features to evaluate potential Project-related effects on the movement of people and animals, as well as the dispersal of plants within a given landscape. Historical linear features are largely naturally revegetated, and more recent linear features are showing good signs of naturally recovering to their original state. Usage of these disturbed areas does not seem to indicate any predatory advantage nor human presence. Two localized conditions limit greater ease of travel. Vegetation is fairly open and has limited effect on impeding movement. Ground cover, thick peat, and graminoid tussocks limit movement (see **Section 9**). Chance shared the *Linear Features Study* (**Appendix 8-B**) Chance recognizes this is a concern and will engage potentially affected First Nations further on this issue.
Porcupine Caribou Herd					
Meeting	Tr'ondëk Hwëch'in	10-Oct-2018	Requested that Chance engage with the PCMB and Tr'ondëk Hwëch'in about the PCH migration through the area.	Chance acknowledged and recorded the comment.	Chance conducted additional wildlife baseline studies, including studying the PCH, in 2018/19 and updated these studies in 2022/23. Chance created a constraints map to identify sensitive or high-quality environmental and heritage values where Project work should be avoided or minimized. See **Sections 3 and 9** for more information.

Interaction Type	Respondent	Date	Comment / Issue	Chance's Response at the Time of Engagement	Chance's Response at Project Proposal Submission
					Chance acknowledges and considers concerns regarding the PCH. Potential effects and mitigation measures to the PCH and Traditional Land Use are discussed in **Sections 9** and **11** of the Project Proposal documents. Chance met with the PCMB on December 1, 2023 and December 20, 2023. Chance will continue to engage with the PCMB.
Meeting	Tr'ondëk Hwëch'in	17-Jun-2020	Suggested that Chance considers potential effects on 40 Mile Caribou Herd and Hart River Caribou Herd in addition to the PCH.	Chance acknowledged and recorded the comment. Chance indicated these suggestions will be considered.	Chance reviewed the Project in relation to the Forty Mile and Hart River caribou herds. The Project is not expected to interact with these herds, and thus were not considered further in the assessment.
Meeting	Tr'ondëk Hwëch'in	08-Jun-2021	Expressed concern for potential Project-related effects on the PCH.	Chance acknowledged and recorded the comment.	Chance conducted additional wildlife baseline studies, including studying the PCH, in 2018/19 and updated these studies in 2022/23. Chance shared the Wildlife Baseline Studies report with Tr'ondëk Hwëch'in for their records. Chance created a constraints map to identify sensitive or high-quality environmental and heritage values where Project work should be avoided or minimized, including caribou habitat. See **Section 9** for more information. Chance acknowledges and considers concerns regarding the PCH. Potential effects and mitigation measures to the PCH and Traditional Land Use are discussed in **Sections 9** and **11** of the Project Proposal.

Interaction Type	Respondent	Date	Comment / Issue	Chance's Response at the Time of Engagement	Chance's Response at Project Proposal Submission
Permafrost and Terrain					
Meeting	Tr'ondëk Hwëch'in	08-Jun-2021	Expressed concern for potential Project-related effects on permafrost.	Chance acknowledged and recorded the comment.	The concerns we heard during this meeting, and others that followed, have been addressed in subsequent meeting presentations as well as within the Project Proposal. Generally, the winter timing and access routing will minimize ground disturbance and potential effects on permafrost and vegetation (See **Sections 4** and **7**).
Community Health and Well-being					
Meeting	Tr'ondëk Hwëch'in	08-Jun-2021	Recognized the PCH have high value as traditional food and for cultural and spiritual well-being.	Chance acknowledged and recorded the comment.	Chance acknowledges the important cultural value, food security, and spiritual importance of the PCH. Chance is committed to reducing potential negative effects on the PCH and other wildlife (see **Sections 9 and 11**).
Employment and Economy					
Meeting	Tr'ondëk Hwëch'in	10-Oct-2018	Expressed interest in Chance sharing job postings throughout the Project for Tr'ondëk Hwëch'in to share with Citizens.	Chance acknowledged and recorded the comment. Chance committed to prioritizing jobs for potentially affected First Nations with Traditional Territories that overlap with the Project footprint first before expanding opportunities to others.	Chance strives to offer training, employment, and contracts to its First Nations partners. During its last drilling/seismic program, Chance successfully hired a workforce from the communities from Old Crow, Fort McPherson, Dawson, Whitehorse, and Inuvik (see **Section 11**). Chance is committed to ongoing consultation and discussions around training, employment, and contracting opportunities with potentially affected First Nations.

Interaction Type	Respondent	Date	Comment / Issue	Chance's Response at the Time of Engagement	Chance's Response at Project Proposal Submission
Mitigations and Monitoring					
Meeting	Tr'ondëk Hwëch'in	12-Aug-2019	Recommended the development of a monitoring program for air quality and emissions.	Chance acknowledged and recorded the comment. Chance recognized that monitoring emissions is costly and that it is not required by legislation at this time.	Chance is committed to conducting monitoring after Project exploration activities are complete (see **Sections 1 and 12**). Chance will not be monitoring emissions as it does not anticipate any significant adverse effects on air quality from the Project.
Email	Tr'ondëk Hwëch'in	24-Jul-2020	Inquired about a Wildlife Management Plan.	Chance acknowledged and recorded the comment.	Chance will develop a Wildlife Management and Monitoring Plan. See **Section 12** of the Project Proposal for more information.
Other					
Meeting	Tr'ondëk Hwëch'in	27-Apr-2021	Suggested that Chance create a specific visual of the Project footprint.	Chance acknowledged and recorded the comment. Chance agreed and stated a desire to create a constraints map for the for the Project Proposal.	Chance created a constraints map to identify sensitive or high-quality environmental and heritage values where Project work should be avoided or minimized. See **Section 3** for more information. Peer Solutions, on behalf of Chance, prepared a Project video showcasing still photos and videos clips of the Project footprint. This video was shared with Tr'ondëk Hwëch'in's technical advisor in August 2023 (**Appendix 2-D**) and made available for download on a secure file sharing site for Tr'ondëk Hwëch'in.
Meeting	Tr'ondëk Hwëch'in	27-Apr-2021	Suggested that Chance create a decision tree to help define the methodology on the categorizations of exploration outcomes.	Chance acknowledged and recorded the comment.	Chance created a constraints map to identify sensitive or high-quality environmental and heritage values where Project work should be avoided or minimized. See **Section 3** for more information.

2.10.9 Ongoing Consultation and Engagement

Chance will continue to consult and engage Tr'ondëk Hwëch'in and residents of Dawson City following submission of the Project. Chance will refine the Program in response to feedback from Gwich'in Tribal during future Project phases, as needed. Planned ongoing consultation and engagement activities include (but are not limited to):

- Project communications (e.g., updates regarding schedule, permitting, monitoring activities, incorporation of Indigenous Knowledge to Project plans, and capacity funding);
- meetings to discuss Project-related effects, issues, and interests;
- opportunities to review and provide comment on Project plans and materials; and,
- opportunities to develop Project-related mitigation measures.

3 METHODOLOGY

3.1 EFFECTS ASSESSMENT

The Eagle Plains Exploration Project (the Project) effects assessment methods described in this section follow guidance provided by Yukon Environmental and Socio-economic Assessment Board (YESAB) in YESAB's Environmental and Socio-Economic Assessment Methodology (YESAB 2021a). The effects assessment follows these basic steps:

- select the Valued Environmental and Socio-Economic Components (VESECs) and related indicators and assessment parameters on which the assessment focuses;
- define spatial and temporal boundaries for the assessment;
- gather data on baseline conditions within the assessment boundaries;
- identify potential effects associated with the Project through an evaluation of potential interactions of the Project with each VESEC;
- define appropriate mitigation to address identified potential effects;
- describe, analyze, and characterize potential residual effects of the Project after incorporating mitigation;
- determine the significance of the residual effects of the Project; and,
- conduct a Cumulative Effects Assessment (CEA) by describing whether the residual effects of the Project for a given environmental or socio-economic component have the potential to interact with other past, present, or reasonably foreseeable future projects or activities to create an adverse cumulative effect.

3.1.1 Assessment Scope

The scope of the assessment is defined by the issues, VESECs, indicators and assessment parameters that will be used to assess the effects of the Project, in combination with the spatial and temporal boundaries of the assessment. The following subsections define these topics in more detail.

3.1.1.1 Issues

Issues scoping involved compiling and analyzing available information to identify environmental, economic, social, heritage, and health issues that could occur as a result of the Project. Information compiled and reviewed included legislation and regulations, approved regional land use plans, community engagement inputs, public comments from open houses, and an evaluation of identified concerns on similar projects in the region and elsewhere. The following key issues and concerns were identified:

- degradation of permafrost;
- terrain instability;
- reductions in water quantity and quality;
- degradation or loss of watercourses and wetlands;
- fish habitat loss and degradation;
- creation of barriers to fish passage;
- in-stream water withdrawals affecting over-wintering fish habitat;
- facilitated human access resulting in increased harvesting of fish;
- concern about Project access roads and effects to water and fish;

- loss of tamarack;
- direct wildlife habitat effects, including habitat loss, alteration and fragmentation;
- indirect wildlife effects including reduced use or avoidance of habitats;
- facilitated human and predator access, and resultant effects on predator-prey relationships, due to seismic line clearing;
- effects on migratory birds;
- effects on American marten;
- effects on moose;
- effects on the Porcupine Caribou Herd (PCH) and concern about their decline;
- degradation of air quality;
- Project-related effects on climate change;
- damage or loss of heritage resources;
- effects on First Nations culture, way of life, and land use;
- employment, training, and procurement opportunities;
- concern about effects to traditional trails and traditional sites related to cultural use areas for trapping and hunting (i.e., moose and caribou);
- increased access to traditional territories and resulting damage to the livelihood of First Nations Citizens;
- impacts to the potential visual impacts to the landscape;
- concern about the human land use-related disturbances such as noise, smell, and light and potential mitigations;
- concern related to increased traffic on the Dempster Highway; and,
- concern over increased risk of increased ski-doo traffic and access management.

3.1.1.2 Valued Environmental and Socio-economic Components

VESECs were identified based on the results of key issues scoping noted above. The issues were grouped into two broad categories: Environmental and Socio-economic. These issues were then further grouped to help focus the assessment and minimize the degree of duplication and redundancy.

The following VESECs were selected for the Project Proposal:

Environmental:

- Permafrost and Terrain;
- Water Resources;
- Fish and Fish Habitat;
- Vegetation;
- Wildlife and Wildlife Habitat; and,
- Caribou.

Socio-economic:

- Heritage Resources;
- Community Infrastructure and Services;
- Land and Resource Use;
- Community Health and Wellbeing; and,
- Employment and Economy.

The rationale for their selection is summarized in **Table 3-1.**

3.1.1.3 Indicators and Assessment Parameters

For an effect to occur, there must be a measurable change in the condition of the VESEC and a corresponding effect on at least one indicator for a VESEC. Each VESEC has at least one indicator (e.g., habitat), and each indicator has at least one assessment parameter, which is defined as a quantitative or qualitative measures of the Project's effects on the indicator (e.g., quantitative change in habitat). **Table 3-2** lists the indicator(s) and assessment parameter(s) for each VESEC. Details, as necessary, are provided in the individual VESEC sections.

Table 3-1. Valued Environmental and Socio-Economic Components and Rationale for Selection for the Eagle Plains Exploration Project

VESECs	Rationale for Selection
Environmental	
Permafrost and Terrain	Changes in permafrost and terrain stability can result in ecosystem changes, slumping, sedimentation in waterways, and other effects
Water Resources	• Potential effects on surface water quality from Project activities • Important to human use and health (drinking water) • Traditional use and related legislation • Strong link to fish and fish habitat • Key attribute of healthy and functioning aquatic and terrestrial ecosystems
Fish and Fish Habitat	• Potential habitat loss from water withdrawal in higher-order streams in winter • Traditional and current food source • Social and cultural importance • Fish that may be exposed to chemical changes in surface water, dietary items or sediment because of the Project • Potential need for authorization under the *Fisheries Act*
Vegetation (including tamarack and ecological communities of conservation concern)	• Tamarack identified as culturally important during Indigenous community meetings • Ecological communities of conservation concern may have limited availability on the landscape
Wildlife and Wildlife Habitat (including Marten, Moose, and Birds).	• Marten: Importance as a furbearer (trapping resource) and indicator of mature and old-growth forest • Moose: Cultural importance and traditional harvest • Birds: Potential presence of eight species of federal conservation concern
Caribou	• Caribou hold Indigenous, regulatory, stakeholder and conservation importance • Caribou can be susceptible to activities that remove or degrade habitat, or facilitate increased access by wolves and hunters • The North Yukon Regional Land Use Plan identifies the PCH as a key concern
Socio-economic	
Heritage Resources	Social/cultural importance
Community Infrastructure and Services	Social importance of community-related infrastructure and services in the vicinity of the Project

VESECs	Rationale for Selection
Land and Resource Use	Social/cultural importance of current land and resource Social/cultural importance of traditional land and resource
Community Health and Wellbeing	• Social/cultural importance of health and well-being of nearby communities • Potential for changes to food and drinking water access and availability and human health
Employment and Economy	• Potential demands for labour, goods and services that could affect local employment and business opportunities, and the regional or local economy

Table 3-2. Valued Environmental and Socio-Economic Components, Indicators and Assessment Parameters Considered in the Environmental Assessment of the Eagle Plains Exploration Project

VESECs	Indicator	Assessment Parameters	Notes
ENVIRONMENTAL			
Permafrost and Terrain	Permafrost	• Changes to ground temperature • Changes to active layer thickness • Changes to ice content	Project activities could locally degrade (thaw) ice-rich permafrost and/or destabilize slopes
	Terrain stability	• Changes to ground settlement and/or mass movement • Changes to surface drainage • Changes to slope morphology	
Water Resources	Surface water quality	• Change in sedimentation and total suspended solids • Change in contaminant and nutrient influxes • Changes in thermal regimes	Water quality could be affected by Project activities
	Hydrology	Change in flows, water levels	Water quantity could be affected by Project activities
Fish and Fish Habitat	Mortality risk	Change in mortality risk	Project activities, including seismic activities and water withdrawal, could increase mortality risk for fish
	Habitat quality	Change in habitat quality	Project activities could result in alteration of habitat quality from water withdrawal,

VESECs		Indicator	Assessment Parameters	Notes
				sedimentation, and removal of riparian vegetation
		Habitat quantity	Change in habitat quantity	Water withdrawal may decrease the quantity of available fish habitat
Vegetation		Tamarack-producing ecosystem units	Change in area (ha) of tamarack producing ecosystem units.	Project activities could result in alteration and/or loss of tamarack
		Ecosystem units of conservation concern	Change in area (ha) of ecosystem units of conservation concern	Project activities could result in alteration and/or loss of ecosystem units of conservation concern
Wildlife and Wildlife Habitat	**Marten**	Habitat	Change in habitat	Project activities could result in habitat alteration and/or loss
		Mortality risk	Change in mortality risk	Increased access from Project activities may affect marten harvesting
	Moose	Habitat	Change in habitat	Project activities could result in habitat alteration and/or loss
		Mortality risk	Change in mortality risk	Project activities could directly and indirectly increase mortality risk for moose
	Bird Species at Risk	Habitat	Change in habitat	Project activities could result in habitat alteration and/or loss
Caribou		Direct habitat effects	Change in suitable habitat within the Project Footprint	Project activities could result in direct habitat alteration and/or loss
		Indirect habitat effects	Change in suitable habitat within a Zone of Influence (ZOI)	Project activities could result in avoidance of habitat due to sensory disturbance
		Movement	Change in movements based on a ZOI	Project activities could result in changes in caribou movements due to sensory disturbance
		Mortality risk	Change in mortality risk	Mortality risk could be affected directly and indirectly by Project activities
SOCIO-ECONOMIC				
Heritage Resources		Known Heritage Resource sites	Disturbance of a Heritage Resource sites	Project activities could disturb known or undocumented Heritage Resources

VESECs	Indicator	Assessment Parameters	Notes
	Areas of potential for undocumented Heritage Resource sites		
	Chance finds of Heritage Resources		
Community Infrastructure and Services	Housing and Accommodation	Changes in demand for housing and temporary accommodation	Community-related infrastructure and services near the Project could be affected directly or indirectly through incremental demand on local infrastructure and services.
	Physical Infrastructure	Changes in demand on physical infrastructure (water, waste, energy infrastructure)	
	Community Services	Changes in demand on community and social services (emergency and health, education, and other social services)	
	Transportation	Changes in pattern of use for transportation infrastructure (traffic volumes, road conditions)	
		Changes in safe use of transportation infrastructure	
Land and Resource Use	Commercial and Recreational Land and Resource Use	Change in area available for and access to current land uses	Commercial and recreational land and resource use refers to the designated and undesignated use of lands and resources for commercial and recreational purposes. Commercial and recreational land and resource use in the vicinity of the Project could be affected directly or indirectly through Project components and activities that alter access, area use, or environmental conditions for current land and resource use.
		Changes in resource availability or abundance	
		Change in environmental conditions (e.g., air quality, noise and vibration, visual quality) that influence user's experience on the land	
	First Nations Culture and Land and Resource Use	Changes to cultural use areas and access	Current First Nations culture and land and resource use are important values of potentially affected First Nations. Traditional land and resource use activities support the socio-economic wellbeing of First Nations and their respective citizens and contributes to their cultural identity and practices.
		Changes in resource availability, abundance, or quality for subsistence activities	
		Changes in cultural identity and transfer of traditional knowledge	

VESECs	Indicator	Assessment Parameters	Notes
Community Health and Wellbeing	Environmental Quality	Human health risk factors from exposure to affected environmental media (surface water, groundwater, soil, air quality, sediments, sensory conditions)	Community health and well-being could be affected directly or indirectly through Project components and activities that contribute to changes in environmental quality, posing a possible risk to human health. Community health and wellbeing may also be directly or indirectly affected by Project components and activities that change social determinants of health and well-being.
		Changes in traditional food quality	
		Changes in public or occupational safety risk (emergency preparedness plan, malfunctions, and accident risk)	
	Social Determinants of Health and Perceived Effects on Health	Changes to community health-related to infectious and chronic disease	
		Changes to community mental health and wellness (stress, substances use, sense of community)	
		Changes in food security status (traditional food quality, quantity, availability, access and perceived effects)	
		Changes in community safety or security (crime, injury, accidents)	
		Changes in personal or relational safety (in camp, in community)	
		Changes in healthcare services demand (e.g., access, capacity for non-emergency services)	
		Changes in Indigenous cultural health (e.g., perceived access to land and impact on health, access to traditional cultural use activities and impact on health)	
Employment and Economy	Employment and Labour	Changes in employment and income	• Employment and economy could be affected directly or indirectly through project demands for labour, goods and services that would affect local employment and business opportunities, and the regional or local economy. • Economic growth and diversification could be affected directly or indirectly from incremental Project demands for local/regional labour, resources, and third-party services. Furthermore, Project demands for community infrastructure and services has the potential to influence local/regional government finances.
		Changes to traditional (non-wage) economic activities	
		Changes in contracting opportunities	
	Economic growth and diversification	Changes in economic diversity and dependency	
		Changes to local-regional governments expenditures and revenues	

3.1.1.4 Assessment Boundaries

Assessment boundaries focus the extent of the assessment. Assessment boundaries for the Project fall under four categories:

- spatial boundaries;
- temporal boundaries;
- technical boundaries; and,
- administrative boundaries.

Each of these four assessment boundaries are defined and described below.

3.1.1.4.1 Spatial Boundaries

Spatial boundaries encompass the areas within which the effects of the Project are expected to interact with the VESECs and indicators. The Project was assessed using five types of spatial boundaries, though not all were used for all VESECs. **Table 3-3** describes each of these spatial boundaries. VESEC-specific definitions are provided where appropriate within the relevant sections of the Project assessment.

Table 3-3. Spatial Boundaries Used for the Project Effects Assessment of the Eagle Plains Exploration Project

Spatial Boundary	Description of Area
Project Footprint	The area where ground will be disturbed, and Project activities will occur.
Zone of Influence (ZOI)	Characterized as an area defined by a distance buffer from the Project Footprint to assess the indirect effects on the Wildlife and Wildlife Habitat, and the Caribou VESECs. The ZOIs are intended to represent areas where sensory disturbance from Project effects could reduce habitat effectiveness and are specific to each wildlife species to which they are applied. ZOIs are based on the best available information and further described as applicable within **Section 8** and **Section 9** of the Project Proposal.
Local Study Area (LSA)	Encompasses the area within which the Project is expected to interact with and potentially result in changes to the VESECs through both direct and indirect effects. Due to the uncertainty in the Project Footprint, LSAs were not defined for all VESECs; in these cases, the Regional Study Area (RSA) was the primary area of consideration for Project effects. Where applicable, LSAs are further defined within the VESEC-specific assessments.
Regional Study Area (RSA)	Potential effects for all VESECs were considered within the context of the RSA. For most biophysical VESECs and for Heritage Resources, the RSA was delineated to encompass the Project's related exploration claim areas. For the Socio-economic VESECs, individual RSAs were defined for each and are further described in **Section 11** of the Project Proposal.
Caribou Study Areas (CSAs)	Potential effects for caribou were considered within the context of multiple spatial scales that are specific to caribou: (1) the RSA, (2) the Eagle Plains ecoregion, and (3) the extent of the rut/ late fall and winter seasonal ranges for the PCH. These scales of analysis correspond to the CSAs, and are further described in **Section 9** of the Project Proposal.

3.1.1.4.2 Temporal Boundaries

Temporal boundaries encompass the time the Project is expected to interact with the VESECs and indicators. The Project will be conducted in one phase: Exploration. This Exploration phase will occur over

approximately 10 years, with all Project activities occurring somewhat concurrently during this phase (Project infrastructure/well development, drilling, extended flow testing).

3.1.1.4.3 Technical Boundaries

Technical boundaries represent limitations on the predictability of Project effects. These boundaries are often specific to individual VESECs, though not always. Where technical boundaries apply to specific VESECs, they are described in detail within the relevant VESEC assessments. The following technical boundaries apply to the Project Proposal assessment:

- The specific locations of some Project footprints (well sites, well access roads, secondary camps) are not defined in the Project Proposal. The nature of the Project activities means that some Project footprint components will be determined after earlier Project activity results (e.g., results from drilling and seismic activities will help to define future drilling locations).
- The assessment of First Nations Culture and Land and Resource Use, and the linkages of individual VESECs to this assessment, is constrained by the availability of Traditional Knowledge used to support an understanding of the use of lands and resources by First Nations for cultural activities.

3.1.1.4.4 Administrative Boundaries

Administrative boundaries represent any constraints that may be placed on the effects assessment due to political, social, and economic realities. Often, these administrative boundaries result in constraints on some data inputs for an assessment (e.g., census subdivisions). Where administrative boundaries apply to specific VESECs, they are described in detail within the relevant VESEC assessments. The following administrative boundaries apply to the entire Project assessment:

- The effects assessment is limited to within the Yukon, Canada; and,
- The effects are considered in the context of the land use designations in the North Yukon Land Use Plan and Peel Region Land Use Plan.

3.1.2 Baseline Conditions

YESAB defines baseline condition as a reference point to analyze the predicted change in the condition of a VESEC as a result of the proposed project activities and associated effects (YESAB 2021a). For each selected VESEC, baseline conditions in the Project study areas are appropriately and adequately described based on a review of existing desktop information and results of field studies. The description of these baseline conditions supports and informs the identification of potential Project interactions with VESECs, and the evaluation and characterization of those interactions. Summaries of baseline conditions are included within relevant sections of the assessment for each VESEC, with additional detail provided within appended baseline reports.

3.1.3 Exploration Project Planning Context

As mentioned in **Section 3.1.1.4.3** the specific locations of exploration wells and well access roads linking the wells to the mainline road network cannot be pre-defined at the Project Proposal stage; many other Project Footprint details (e.g., main road network, camp location, airstrip, seismic lines) are, however, defined. The location of wells depends on the results of the seismic exploration and the information collected from any preceding wells. In addition, some secondary Project feature locations (e.g., secondary

camp locations) are also not confirmed. Therefore, a series of plausible well site location scenarios were developed to assess the potential effects of wells, well access roads, and secondary camp locations on spatially-explicit values for applicable VESECs. Multiple scenarios were developed to estimate a range of possible effects on the environment.

Ten scenarios were developed. Exploration personnel manually mapped one scenario, and nine scenarios were modelled in GIS. Each scenario consisted of 30 discreet well sites and 30 well access roads, with one access road for each well site linking it to the mainline road network. The locations of wells were selected to avoid or minimize overlap with environmental constraints (see **Section 3.1.3.1**), consistent with mitigation measures that are planned for well site development. For the manually mapped scenario, potential resource targets were considered in well site selection based on historical exploration information. However, these targets are preliminary and could change substantially as new seismic data are obtained and analyzed. For the modelled scenarios, potential resource targets were not considered.

In the manual mapping scenario, the exploration personnel located well sites and spur roads using their best judgement to avoid or minimize overlap with the environmental constraints. In the modelled scenarios, well sites were randomly selected using a weighted-random selection approach, where the probability of selected sites was reduced by 'costs' assigned to each environmental constraint.

For the effects assessments that quantified changes in spatially-explicit indicators (e.g., vegetation), the potential effects of each scenario are quantified, and the range of potential effects across the 10 scenarios are summarized and considered for relevant VESECs.

3.1.3.1 Environmental Constraints Mapping

A constraints map outlines sensitive or high quality environmental and heritage values where Project work is to be avoided or minimized. Developing and applying a constraints map for VESECs is especially useful when certain Project features cannot be preplanned (i.e., mapped), which is the case for the exploration well sites and well access roads for the Project.

Within the constraints mapping and associated well site scenario modeling, a hierarchy for avoidance was assigned to individual environmental or heritage values, aligning with mitigation measures identified for individual VESECs within their mitigation and effects assessment sections. Exploratory wells and spur roads were prohibited (i.e., avoidance) from occurring within heritage sites or in Riparian Reserve Zones (RRZs). Other values including sensitive permafrost areas, Riparian Management Areas (RMAs), ecosystems of conservation concern, high value caribou habitats, and high value moose habitats were avoided where practical, but not entirely (i.e., minimized).

In some cases multiple constraints occurred adjacent to each other, or overlapped, and it was not possible to avoid all constraints. Where that occurred, a priority ranking for avoidance was developed based on a subjective evaluation of the rarity, sensitivity, and importance of the constraints. The priority for avoidance was:

1. Heritage sites;
2. RRZs;
3. Permafrost/terrain sensitive areas;
4. RMAs;
5. Ecosystems of conservation concern;

6. High-value caribou habitat; and
7. High-value moose habitat.

For details on the individual values, and associated mitigation measures for those values (including how they were defined and incorporated into the constraints mapping) refer to the individual assessments for those VESECs.

3.1.3.2 Work Areas

Due to the geographic extent of the Project, work will be broken up into multiple work areas, with operations in each work area anticipated to be for 1–3 years. Conducting the work across different areas in different years is a logistical requirement, given the size of the Project Area. For most footprint-related effects (e.g., direct habitat effects associated with vegetation clearing, erosion risk associated with stream crossings), effects were assessed for the entire 10–year Project period. However, for effects associated with sensory disturbance (e.g., indirect habitat loss and wildlife movement), effects were assessed at the work area level (and associated timescale of 1–3 years per work area) because effects of sensory disturbance are expected to be limited to a single work area at any given stage.

This approach to characterizing effects is required to account for key differences in the duration and persistence of the effects from footprint-related disturbance and sensory disturbances. Footprint-related effects will be assessed cumulatively across the entire RSA. The first footprint disturbances created at the start of the Project will likely still exist when the last footprint disturbance is made at the end of the Project (i.e., the effects of the first footprints will likely not have been reversed before the completion of the last footprints). However, sensory disturbance-related effects are expected to cease immediately or return to pre-disturbance levels quickly once the work activity is completed in a given area.

Successive work areas cannot be planned in advance. The extent (size, location, and boundaries) of work areas are expected to develop iteratively over the Project's life based on existing and future exploration results and logistical constraints (e.g., equipment and personnel availability). Instead of assessing effects for defined portions of the RSA, effects were estimated aspatially as a proportion of the effects for the entire RSA, based on the maximum extent over which exploration activities could occur in any given year. The activity that is expected to have the largest work extent each year is seismic exploration, and the maximum extent over which seismic could occur is 500 square kilometres (km²), or about 21 percent (%) of the RSA. In most years, the extent of seismic explorations will be less than 500 km².

Although most disturbances will be associated with exploration activities within the annual work areas, some Project disturbances are expected to occur each year outside the annual work areas. These activities include the operation of the main camp, the airstrip and access road, and water hauling. One or more winter roads outside the annual work areas may be required to provide access to the work areas from camp. The combined length of access roads off the Dempster Highway for a given work area could vary from zero kilometres for work areas adjacent to the Dempster Highway to 60 kilometres (km) for work areas in the northern portion of the RSA.

Based on the factors discussed, associated with maximum work area size, access roads outside the work areas, and fixed annual Project infrastructure, the maximum annual proportion of the RSA subject to sensory disturbance was estimated to be one third (i.e., 33%) of the RSA. Thus, the maximum extent of sensory disturbance-related effects (e.g., temporary reduced habitat effectiveness for some wildlife VESECs) was calculated for each VESEC by applying the applicable ZOI buffers to each disturbance type across the RSA and then multiplying that total extent by 0.33.

3.1.4 Effects Characterization

3.1.4.1 Project Interactions and Potential Effects

A project effect is a change in the condition of a VESEC caused directly or indirectly by a project. Project components and activities that may interact with a VESEC and potentially cause changes to indicators are identified for each VESEC in an interactions matrix (**Table 3-4)**.

The assessment of the potential effects of project components and activities is based on comparing baseline and predicted future conditions with and without the Project. The interaction matrix provides 1) a tool to assist with understanding the Project components and their high-level interactions with VESECs, and 2) a visual confirmation to reviewers that all Project components and activities have been included in the assessment of each VESEC.

Activities within the matrix have been characterized as having no interaction (0), a minor interaction (1) where an effect is possible but is not expected to be measurable or meaningful (e.g., possible behavioural response for wildlife, but no measurable effect on individual survival or reproduction), or an interaction that may result in a measurable effect (2). Interactions characterized as (2) were carried forward to the residual effects characterization.

The interactions are identified in **Table 3-4**. Details about the Project Components and Activities are presented in **Section 1.3.7**. A more detailed description of the likely interactions are provided in the individual VESEC selections.

Table 3-4. Eagle Plains Exploration Project Interaction Matrix with Valued Environmental and Socio-Economic Components

Project Component / Activity	Environmental VESECs						Socio-economic (VESECs)				
	Permafrost and Terrain	Water Resources	Fish and Fish Habitat	Vegetation	Wildlife and Wildlife Habitat	Caribou	Historic Resources	Community Infrastructure and Services	Land and Resource Use	Community Health and Wellbeing	Employment and Economy
Engagement	0	0	0	0	0	0	0	0	0	0	0
Seismic Exploration	2	2	2	2	2	2	2	1	2	2	+
Drilling Exploration	2	2	2	2	2	2	2	1	2	2	+
Extended Flow Testing (EFT)	0	0	0	0	2	2	1	0	1	1	+
Well Maintenance (Workovers)	0	0	0	0	2	2	1	1	1	1	+
Winter Access Creation and Maintenance	2	2	2	2	2	2	1	0	2	2	0
Mix Bury Cover (MBC) Construction and Operation	2	0	0	0	2	2	2	0	1	1	+
Central Processing Facility (CPF)	2	0	0	2	2	2	2	0	1	1	+
Airstrip Operations	0	2	0	2	2	2	0	0	1	1	+
Water Withdrawal	1	2	2	0	2	2	0	0	1	1	0
Transportation	1	0	0	0	2	2	1	2	1	1	0
Chance Camp Operations	1	2	0	2	2	2	1	1	1	2	+
Reclamation and Closure	2	0	0	0	2	2	2	0	1	1	0

Notes:
+ = beneficial effect
0 = no interaction
1 = minor interaction with VESEC possible, but small immeasurable effect (e.g., possible slight behavioural response, no vegetation effects, no measurable effect on water quality). Designates a summary of effects that are addressed in the effects assessment as a discussion. This rating does not lead into residual effects characterization.
2 = substantial interaction with VESEC, designates a more detailed assessment of potential effects. Carry forward into residual effects characterization.

3.1.4.2 Mitigation Measures

Mitigation measures are actions and measures that Chance Oil and Gas Ltd. (Chance) will use to address potential Project-related adverse effects. Mitigation measures are identified following the mitigation hierarchy approach:

- avoid potential adverse effects;
- minimize effects to the extent possible, if not avoidable, through measures including but not limited to modification of project design or use of abatement technologies; and,
- employ restoration or rehabilitation techniques to treat remaining adverse effects on site.

Chance has made substantial effort to incorporate avoidance and minimization into Project design and operational decisions, in the form of spatial avoidance (e.g., **Section 3.1.3.1 Environmental Constraints Mapping**) and temporal avoidance (i.e., majority of Project activities occurring during winter months, when many VESECs are less sensitive to potential effects). Within each VESEC-specific assessment of the Project Proposal are descriptions of technically and economically feasible measures that Chance proposes to incorporate to mitigate the Project's potential effects. Appropriate mitigation measures have been identified based on a combined evaluation of site-specific conditions, best practices, available and effective technologies, technical and economic feasibility, and professional experience.

Chance identifies several Project-specific Environmental Management Plans (EMPs) that will collate relevant mitigation measures and provide operational implementation guidance during exploration. These EMPs are further described in **Section 12**.

3.1.4.3 Residual Effects Characterization

Residual effects are effects that remain after mitigation. All Project-related adverse residual effects are described and assessed within the residual effects characterization for individual VESECs.

The residual effects characterization uses magnitude, likelihood, geographic extent, duration, frequency, timing, and reversibility. The general residual effect criteria used for the Project are defined in **Table 3-5**, following guidance provided by YESAB (YESAB 2021b). **Table 3-6** provides standardized Project ratings for each criterion; VESEC-specific ratings have been defined within individual VESEC sections where necessary.

Table 3-5. YESAB's Effect Characterization Criteria

Project Activity	Effects Pathway(a)
Magnitude	• Definition: The extent of a Project-related change from baseline conditions — a narrative or quantification. • Explanation: Depending on the effect, magnitude may be measured with familiar units; for example, in describing habitat loss, the change from baseline conditions may be measured in hectares. More abstract measures may be required for other effects, such as effects on heritage resources.
Likelihood	• Definition: The probability that an effect will occur. • Explanation: Some effects may be certain, while others will be unlikely.
Geographic Extent	• Definition: The spatial area(s) in which an effect is predicted to be detectable. • Explanation: The geographic extent of effects can be local or regional; in some cases, the geographic extent may be outside the RSA. For example, some effects may only occur in communities rather than the project location.

Project Activity	Effects Pathway(a)
Duration, Frequency and Timing	• Definition: Duration: The length of time an effect is predicted to last. • Explanation: Certain effects may persist beyond the life of the Project.
	• Definition: Frequency: How often an effect is predicted to occur. • Explanation: Certain effects occur more frequently than others.
	• Definition: Timing: When an effect is predicted to occur. • Explanation: Certain effects depend on the time they occur (e.g. time of year).
Reversibility	• Definition: The degree to which a valued environmental or socio-economic component can be returned to baseline conditions or other established reference point after proposed activities have ceased. • Explanation: Effects can be reversible or permanent. Reversible effects may have lower impacts than irreversible or permanent effects.

Adapted from YESAB 2021a.

Table 3-6. Definitions of Effects Criteria Classifications for the Assessment of VESECs in the Project

Criterion		Rating	Definition
Magnitude		Negligible	There will be no measurable change from existing conditions
		Low	The residual effect will be a slight, but measurable change from existing conditions
		Moderate	The residual effect will be a measurable change from existing conditions but will not affect the VESECs viability, role or function
		High	The residual effect will be a substantial, measurable change from existing conditions that may affect the VESECs viability, role or function
Likelihood		Unlikely	No residual effect is expected, but a residual effect is not impossible
		Possible	A residual effect may occur but is not likely
		Probable	A residual effect is likely to occur, but it is not certain
		Certain	A residual effect will occur
Geographic Extent		Maximum disturbance footprint	The residual effect will be confined to the maximum disturbance footprint
		Local	The residual effect will be confined to the LSA
		Regional	The residual effect will extend beyond the LSA but be confined to within the RSA
		Beyond regional	The residual effect will extend beyond the RSA
Duration, Frequency and Timing	Duration	Short-term	The residual effect will occur for less than one year
		Medium-term	The residual effect will occur for greater than one year and up to the life of the Project
		Long-term	The residual effect will extend beyond the life of the Project

Criterion		Rating	Definition
		Permanent	The residual effect is predicted to be permanent and thus unlikely to recover to existing conditions
	Frequency	Occasional	The residual effect will occur rarely (once or a few times over the life of the Project)
		Periodic	The residual effect will be occur consistently at regular intervals or associated with temporal events (e.g., during spring freshet, low flows, growing season)
		Continuous	The residual effect will occur continuously
	Timing	Year-round	The residual effect will occur year-round
		Seasonal	The residual effect will be confined to a portion of the year
Reversibility		Reversible	The residual effect is predicted to be reversible within a clearly defined period
		Irreversible	The residual effect is predicted to be irreversible

3.1.4.3.1 Context and Confidence

A project's context has a bearing on determining the significance of likely adverse effects and is considered an important input under the *Yukon Environmental and Socio-economic Assessment Act* S.C. 2003, c. 7 (*YESAA*). The following contextual factors are used to support determining the significance of likely adverse project effects: environmental and/or socio-economic context within which the Project occurs (e.g., land use plans); legislation; Indigenous and treaty rights; cumulative effects of other past, present, and likely future projects or activities; standards, plans and policies; ecological or social limits and thresholds; vulnerability and resiliency of social and/or ecological systems and components; political and cultural setting (YESAB 2021b). Context is evaluated separately for the residual effects on each individual VESEC.

Limitations of existing data and uncertainty associated with the assessment were also characterized by assigning a level of confidence for each residual effect. level of confidence is considered concerning:

- scientific certainty relative to the quantification of the effect, including the quality and or quantity of data and the understanding of effect mechanisms;
- scientific certainty relative to the effectiveness of the proposed mitigation; and,
- professional judgment based on prior experience in predicting effects and the known effectiveness of proven mitigation measures.

Confidence estimates are intended to support YESAB and regulator evaluation of risk associated with the Project's residual effects. In the determination of confidence for each residual effect characterization, the following categories are used:

- Low Confidence: is assigned when the VESEC, subcomponent or Project interaction is not well understood, or the mitigation has not been proven effective;
- Moderate Confidence: is assigned where the VESEC is understood in similar ecosystems and effects have been documented in the larger regional area or the literature, and/or the mitigation has been proven effective elsewhere; and,
- High Confidence: is assigned when the VESEC, subcomponent, and Project interactions are well understood, and the mitigation has been proven effective.

3.1.5 Significance Determination

In characterizing the likely or predicted residual effects of the Project, the assessment has included an evaluation of whether those residual effects are likely to be significant or not significant. Magnitude, geographic extent, and duration are typically the primary characteristics affecting significance, with other characteristics acting as modifiers. For example, if an adverse effect of the Project has a sufficiently high magnitude, affects a reasonably large area, and lasts for a sufficient duration, then a significant adverse effect may be identified.

Definitions of significant versus not significant have been provided for each VESEC within the relevant effects characterizations, alongside an evaluation of the significance of residual effects on those VESECs. Defining significance generally incorporates the principles of sustainability and other relevant concepts and considerations, as appropriate. In general, within the Project Proposal, significant environmental effects are those adverse effects that are predicted to cause a change in the VESEC that is likely to alter its status or integrity beyond an acceptable level (e.g., where it is not sustainable or is unavailable to contribute to ecological function or future generations). An effect that does not approach those criteria is considered not significant.

3.1.6 Cumulative Effects

Cumulative effects are changes to environmental, social or economic values caused by the Project's activities when combined with effects of other past, present and reasonably foreseeable future projects or activities (YESAB 2021c). Cumulative effects occur when the Project interacts (spatially and temporally) with residual effects of other projects or activities and creates an effect greater than the Project's residual effect. For the Project, the CEA was completed for all VESECs with potential predicted residual effects with magnitude of low or greater. This process included defining assessment boundaries, identifying cumulative effects within those boundaries, and evaluating the significance of those cumulative effects. The subsections below describe the approach used, and the results of the CEA for each VESEC are presented in the VESEC-specific assessment sections.

3.1.6.1 Cumulative Effects Assessment Boundaries

3.1.6.1.1 Spatial Boundaries

The CEA was completed within spatial boundaries relevant to each individual VESEC. The majority of VESECs assessed cumulative effects at the scale of (**Table 3-7**):

1. the general Cumulative Effects Study Area (CESA); and
2. the Caribou Cumulative Effects Study Area (CCESA).

Cumulative effects for many VESECs were assessed within the Land Management Units (LMU) of the North Yukon Land Use Planning and the Peel Watershed Planning regions that overlap with the Project. In the North Yukon Planning Region, this is LMU #9 (Eagle Plains); in the Peel Watershed Planning Region, this is LMU #7 (Daglish Creek). These boundaries were selected for assessing cumulative effects for many VESECs because cumulative effects indicators have been adopted for each LMU in these planning regions and provide the context within which the results of the CEA can be interpreted (**Section 1.6** of **Section1 Details of the Project Description** of the Project Proposal). Cumulative effects on caribou were assessed within the Canadian portion of the PCH range. Cumulative effects for socio-economic VESECs were

assessed at scales relevant to each of those four individual VESECs, as listed below and further defined within **Section 11 Socio-Economics** of the Project Proposal.

Table 3-7. Spatial Boundaries Used for the Cumulative Effects Assessment of the Eagle Plains Exploration Project

VESEC	CEA Spatial Boundary	Description of Area
• Permafrost and Terrain • Water Resources • Fish and Fish Habitat • Vegetation • Wildlife and Wildlife Habitat • Heritage Resources	Cumulative Effects Study Area (CESA)	The extent of the combined areas of LMU #9 in the North Yukon Planning Region and LMU #7 in the Peel Watershed Planning Region.
Caribou	Caribou Cumulative Effects Study Area (CCESA)	The Canadian portion of the PCH range.
Land and Resource Use	Land and Resource Use RSA	Game Management Subzones overlapping the Project Footprint where the Project could affect regional management of wildlife and harvesting
Employment and Economy	Employment and Economy RSA	The boundaries of the regional government and municipalities from which the Project could potentially source business services and labour.
Community Infrastructure and Services	Community Infrastructure and Services RSA	The boundaries of the regional government and municipalities from which the Project may potentially source municipal services and infrastructure and related regional public transportation networks.
Community Health and Well-being	Community Health and Well-being RSA	For the Community Health and Well-being - Environmental Determinants of Health subcomponent: the Game Management subzones overlapping the Project Footprint where the Project could affect regional management and harvesting of wildlife in its relation to environmental determinants to human health outcomes. For the Community Health and Well-being - Social Determinants of Health subcomponents: the boundaries of the regional government and municipalities from which the Project may potentially source community health and social services related to well-being.

3.1.6.1.2 Temporal Boundaries

For the CEA, temporal boundaries were defined as follows:

- Past: includes projects and activities that were completed before 2024. For projects and activities within the RSA, the spatial effects of these projects are generally considered to be contained within baseline spatial data (e.g., existing roads, seismic lines, etc.).
- Present: includes projects and activities initiated before 2024 and currently operating in 2024.
- Future: includes projects and activities proposed to start at some point between the time the CEA was completed (early 2024) and the end of Project activities (2035, 10 years after the

start of the Project, assuming 2025 start date). The effects of the Project can be expected to last beyond 2035 while disturbed land goes through reclamation and restoration. However, 2035 represents the peak of potential future cumulative effects to which the Project contributes.

3.1.6.2 Cumulative Effects Analysis

3.1.6.2.1 Projects and Activities

A list of past, present, and reasonably foreseeable future projects and activities with potential to interact spatially and temporally with the Project was compiled (**Table 3-8**). This list of projects and activities that can contribute to cumulative effects on the VESECs was collated from multiple sources including:

- the YESAB Project Registry;
- the final Land Use Plans for the North Yukon and Peel Watershed Planning Regions (North Yukon Planning Commission 2009, Peel Watershed Planning Commission 2019);
- geospatial data from the Yukon Government;
- other publicly available data; and,
- input from individuals working in these regions.

Each project was assigned a complete, ongoing, or proposed status based on its temporal status and activity status, as described in the YESAB Project Registry and other best available information. In many cases, information on the temporal status of a project was not readily available, including projects in the YESAB Project Registry where the approval was listed as “vary”, which indicated the project was approved with changes to the proposal. In those cases, the Registry did not further indicate the project's temporal status. To take a conservative approach, we assumed any project with a “vary” approval proceeded and was either complete, operating or ongoing based on other available data (e.g., review of satellite imagery, proposed project start and end times, etc.).

Many disturbances (gravel quarries, oil and gas projects, or mining projects) were in the Geo Yukon Areal Surface Disturbance layer (most recently updated in 2021 (Powell 2023), but were not in the YESAB Project Registry. These disturbances had no information associated with them other than the type of industry, type of disturbances, and area. Given their continued, visible presence on the landscape, these projects were assumed to have remaining residual effects that could interact with Project residual effects and were included in the CEA.

Besides expeditions on the Firth River, many tourism activities in the YESAB Project Registry only occurred for one season. In the case of these short-term activities, it was typically assumed that no remaining residual effects were interacting with Project residual effects, and these projects were not carried forward.

Table 3-8. List of Other Past, Present, and Reasonably Foreseeable Future Projects and Activities Included in the Cumulative Effects Assessment

Industry	Project Name/ Activity	Activity Status	Location	Proponent
Transportation	Dempster Highway	Ongoing	LU Planning Regions	Government of Yukon
	Ogilvie Grader Station Solar, km 195 Dempster Highway	Ongoing	PCH Range	Government of Yukon
	Old Crow Winter Road	Ongoing	LU Planning Regions, PCH Range	Government of Yukon and Vuntut Gwitchin Government
	Old Crow all-season road/	Proposed	LU Planning Regions, PCH Range	Government of Yukon and Vuntut Gwitchin Government
	Wind River Trail and Hart River Winter Road	Ongoing	LU Planning Regions	Unknown, historic exploration or seismic lines
	Various Transportation Infrastructure	Ongoing	LU Planning Regions	Various
Communities and community infrastructure	Communities of Old Crow and Eagle Plains, Homesteads, and Camps	Ongoing	LU Planning Regions, PCH Range	Vuntut Gwitchin Government, Yukon Government
	Eagle Plains Solid Waste Disposal	Ongoing	LU Planning Regions	Yukon Government
Gravel Quarry	Gravel quarries – Unnamed	Ongoing	LU Planning Regions	Unknown
	Sheep Creek Gravel Pit, km 433 Dempster Highway	Ongoing	PCH Range	Yukon Government
	Gravel Extraction and Crushing North and South Cornwall Rivers	Complete	PCH Range	Yukon Government
	Porcupine River Gravel Development	Complete	PCH Range	Yukon Government
	Granular Pit Exploration + Development – km 158	Ongoing	PCH Range	Yukon Government
	Granular Pit Development km 226 Dempster Highway	Ongoing	PCH Range	Yukon Government
	Dempster Highway Granular Pit Development: km 188, 208, and 232	Proposed	PCH Range	Government of Yukon

Industry	Project Name/ Activity	Activity Status	Location	Proponent
Oil and Gas	Oil and Gas Exploration Drilling	Complete	LU Planning Regions, PCH Range	Chance Oil and Gas Limited (then Northern Cross Limited)
	Flow Tests at Three Existing Hydrocarbon Wellsites	Complete	LU Planning Regions, PCH Range	Chance Oil and Gas Limited (then Northern Cross Limited)
	Quarry Pit Development for Wellsite Access Road, Eagle Plains-Northern Cross	Complete	LU Planning Regions, PCH Range	Chance Oil and Gas Limited (then Northern Cross Limited)
	Northern Cross – 2008 Winter Drilling Program	Complete	LU Planning Regions, PCH Range	Chance Oil and Gas Limited (then Northern Cross Limited)
	Northern Cross Yukon Limited – 2008 Summer Drilling Program	Complete	LU Planning Regions, PCH Range	Chance Oil and Gas Limited (then Northern Cross Limited)
	Northern Cross Yukon Limited – Eagle Plains Resource Assessment Programs (Construction of Camp)	Ongoing	LU Planning Regions, PCH Range	Chance Oil and Gas Limited (then Northern Cross Limited)
	Blackie M-59 Re-Evaluation Program (Oil and Gas exploration)	Complete	LU Planning Regions, PCH Range	Chance Oil and Gas Limited (then Northern Cross Limited)
	Eagle Plains 3D Seismic Survey	Complete	LU Planning Regions, PCH Range	Chance Oil and Gas Limited (then Northern Cross Limited)
	Eagle Plains Well Maintenance and Exploration	Ongoing	LU Planning Regions, PCH Range	Chance Oil and Gas Limited
	Re-Abandonment of Petroleum Exploration Well B-62	Ongoing	PCH Range	Yukon Government
	Oil and Gas	Ongoing/ Complete	LU Planning Regions	Various (Geo Yukon Surface Disturbance Layer)
Communications	Yukon Fiber Optic Network	Ongoing	LU Planning Regions, PCH Range	Government of Yukon
	ROHL Camp	Ongoing	LU Planning Regions, PCH Range	ROHL (Dempster Fiber Line)
Tourism	Tourism	Ongoing/ Complete	LU Planning Regions	Various

Industry	Project Name/ Activity	Activity Status	Location	Proponent
	Firth River Rafting/Expeditions	Ongoing/ Complete	PCH Range	Various: Nahanni River Adventure Ltd., Canadian River Expeditions, The Explorers League, ROAM Adventures
Recreation	Recreation Use	Ongoing	LU Planning Regions	Various
Resource Harvesting	Non-commercial Fishing	Ongoing	LU Planning Regions	Residents
	Non-commercial Hunting	Ongoing	LU Planning Regions	Residents
	Trapping	Ongoing	LU Planning Regions	Various
	Big game outfitting	Ongoing	LU Planning Regions	Various
	Forest harvesting	Ongoing	LU Planning Regions, PCH Range	Various
Mineral Exploration	Mineral Exploration	Ongoing/ Complete	Regional	Various (Geo Yukon Surface Disturbance Layer)
	Kit Property	Complete	PCH Range	Strategic Metals Ltd.
	Michelle Property Exploration	Complete	PCH Range	Archer Cathro and Associates
	Quartz Mining – Shell Creek Property	Complete	PCH Range	Logan Resources
	OG Property	Complete	PCH Range	Full Metal Mineral Ltd.
	Quartz Exploration – Victoria Mountain	Complete	PCH Range	Aurchem Exploration Ltd.
	Quartz Exploration – Coal Creek (Monster)	Ongoing	PCH Range	Go Metals Corp.
Military	Bar-2 Shingle Point Long Range Radar Military Facility	Ongoing	PCH Range	Department of National Defense
	BAR-2 (Shingle Point, Yukon) Fuel Tank W22 B Upgrade	Ongoing	PCH Range	Department of National Defense
	Crush Gravel, Stockpile and Resurface Runway at BAR-2 (NWS radar Site 8 km SE of Shingle Point	Complete	PCH Range	Department of National Defense

Industry	Project Name/ Activity	Activity Status	Location	Proponent
	Bar-2 Shingle Point – HV Power Distribution Overhaul	Complete	PCH Range	Department of National Defense
Ivvavik National Park Operations	Sheep Creek Base Camp, Ivvavik National Park	Ongoing	PCH Range	Parks Canada
Other	Contaminated sites	Ongoing	Regional	Various
	IBC Camp on US/CA Border	Complete	PCH Range	International Boundary Commission

3.1.6.2.2 Cumulative Effects Characterization

Cumulative effects on a VESEC were considered if potential residual effects from the Project might interact with the effects from past, present, or reasonably foreseeable future projects and activities. Potential residual effects of projects and activities listed in **Table 3-8** were considered if they might interact with a given VESEC. Effects from other projects and activities were determined through a review of reports on the YESAB registry or other sources.

For each VESEC, a description of existing and predicted future conditions was provided using information and context as was relevant for that particular VESEC. Potential cumulative effects were determined by comparing existing conditions to future conditions. Future conditions combined existing conditions with predicted effects of all reasonably foreseeable future projects, including the Project.

All quantitative, spatially relevant effects (e.g., area of disturbed land) were assumed to be additive where they did not spatially overlap with another project or activity with the same type of effect. If a project or activity spatially overlapped with another project or activity, the more recent project or activity (temporally) was typically assumed to take precedence. The exception was if a project or activity was intended to remediate a historic disturbance (e.g., remediate a contaminated site).

Additional Project-specific mitigation measures might be proposed if an adverse cumulative effect was identified for a VESEC. After the incorporation of mitigation, all residual cumulative effects are characterized following the same methods as potential residual effects, as outlined in **Section 3.1.4**.

3.2 CONSIDERATION OF TRADITIONAL/INDIGENOUS KNOWLEDGE

Chance contacted potentially affected First Nations to inform them that an environmental and socio-economic assessment was being conducted for the Project Proposal, and that they planned to identify and apply existing Traditional Knowledge sources, including publicly available studies or reports, related to the Project area. Chance advised that they intended to use only Traditional Knowledge information that was relevant to understanding potential effects to First Nations. Chance also requested each potentially affected First Nation to identify and describe Traditional Knowledge confidentiality and protocols that may be applicable.

Chance acknowledged that Traditional Knowledge sources may include studies prepared for other regulatory processes, First Nation published documents, and other sources of publicly available information including books, articles, and reports. Chance confirmed that including Traditional Knowledge into the environmental and socio-economic assessment would support the understanding of existing environmental and socio-economic conditions and potential Project-related effects, and possibly inform mitigations or enhancement measures. Two Worlds Consulting, on behalf of Chance, identified existing secondary sources of Traditional Knowledge for each potentially affected First Nation to review, and requested their permission to use the sources in preparing the socio-economic assessment. First Nation-specific sources were outlined in a table and shared with each potentially affected First Nation by email. Additional information provided for each source included the document title, author, summary of the source, and URL (if available). Two Worlds Consulting offered to provide PDF copies of sources shared, if requested. **Table 3-9** identifies all secondary Traditional Knowledge sources shared with potentially affected First Nations for review and permission.

Table 3-9. Secondary Traditional Knowledge Sources Identified for Review by Potentially Affected First Nations

Document Title	Source	Summary	URL (if available)
First Nation Na-Cho Nyäk Dun			
YESAB # 2022-0090 Dempster Highway Shoreline Stabilization	YESAB	Traditional Territory is heavily altered from First Nation Na-Cho Nyäk Dun's pre-contact baseline, which has impacted cultural and traditional practices. Historical and ongoing impacts, impacts to heritage resources, and impacts to traditional use locations. First Nation Na-Cho Nyäk Dun stated they hold traditional knowledge information on moose, caribou, arctic grayling, and traditional camp/fish locations.	PDF copy available upon request
YESAB # 2022-0172, Quartz Exploration - Clear Creek	YESAB	First Nation Na-Cho Nyäk Dun outlined the important importance of traditional knowledge as speaking to the harvesters' and other observers' experiences of population declines and how the declines impact Indigenous Nations' constitutionally protected treaty rights.	PDF copy available upon request
First Nation of Na-Cho Nyäk Dun Traditional Knowledge Policy	EthicsHub	First Nation Na-Cho Nyäk Dun define and describe traditional knowledge, guidelines for disclosure of traditional knowledge, and outlines sensitivity level categories for traditional knowledge.	PDF copy available upon request
DÄN HÙNÀY Our People's Story: First Nation of Na-Cho Nyäk Dun Elders' Memories and Opinions on Mining	First Nation of Na-Cho Nyäk Dun	Collection of oral history from 2015 and 2019 on First Nation Na-Cho Nyäk Dun Citizens' experiences with the mining industry since 1915.	PDF copy available upon request
Gwich'in Tribal Council / Tetł'it Gwich'in Council			
Nan Geenjit Gwitr'it T'agwàa'in: Working for the Land (Gwich'in Land Use Plan)	Gwich'in Land Use Planning Board	Land Use Planning Board specify special management zones and conservation zones throughout Tetł'it Traditional Territory, traditional/cultural activities, and heritage resources.	PDF copy available upon request
Ways We Respect Caribou: Teetł'it Gwich'in Rules	University of Calgary	Discusses key traditional locations for Tetł'it Gwich'in when seeking caribou, and key harvesting times which were in fall and winter. Caribou harvesting today takes place throughout the Dempster Highway corridor. Number	PDF copy available upon request

Document Title	Source	Summary	URL (if available)
		of caribou harvested varies significantly by season, reflecting ecological and socio-economic factors.	
Gwich'in Harvest Study	Gwich'in Renewable Resources Board	Study includes a full species list for the study, and data on total harvests per species per year. Harvesting locations were kept confidential.	PDF copy available upon request
Gwich'in Tribal Council Website	Gwich'in Tribal Council	Outline legends regarding animals and early humans. Timeline of events post-contact at bottom of the History page.	HISTORY – GWICH'IN TRIBAL COUNCIL (gwichintribal.ca)
Gwich'in Renewable Resources Workshop	Gwich'in Language Teaching & Learning Centre	Legends and stories of wildlife and human interactions.	PDF copy available upon request
Gwich'in Traditional Knowledge: Nèhtrùh (Wolverine)	Gwich'in Renewable Resources Board	Traditional knowledge, legends, and stories about Wolverine.	PDF copy available upon request
Gwich'in Knowledge of Grizzly Bears	Gwich'in Social and Cultural Institute/Gwich'in Renewable Resources Board	Traditional knowledge and legends of Grizzly Bear.	PDF copy available upon request
Gwich'in Traditional Knowledge: Woodland Caribou, Boreal Population	Gwich'in Social and Cultural Institute	Traditional knowledge, legends, and significance of Woodland Caribou (Boreal population).	PDF copy available upon request
Gwich'in Knowledge of Bluenose Caribou	Gwich'in Social and Cultural Institute/Gwich'in Renewable Resources Board	Traditional knowledge and legends of Bluenose West Caribou.	PDF copy available upon request
TS'IIDĘ́Ų GWÌNOO GWINÌN: Animals from Long Ago	Gwich'in Social and Cultural Institute	Gwich'in stories and information about animals and legends of mythical creatures including bison, mammoths, giant caribou, legend of Raven, giant creatures, and more. Maps included for place names.	PDF copy available upon request
Fonds 426 – Gwich'in Tribal Council – Gwich'in Social and Cultural Institute Fonds	Government of Northwest Territories	Includes the fonds of historic sites, traditional knowledge work, and more.	Gwich'in Tribal Council – Gwich'in Social and Cultural Institute fonds – NWT Archives (accesstomemory.org)

Document Title	Source	Summary	URL (if available)
Gwich'in Place Names Atlas	gwichin.ca	An interactive online Atlas that explores the culture, history, traditional knowledge and land use of the Gwich'in through Gwich'in place names.	Atlas (gwichin.ca)
Tr'ondëk Hwëch'in			
Re: Quartz Exploration – Michelle Creek (2021-0176)	YESAB	Tr'ondëk Hwëch'in submitted comments stating the Michelle Creek Quartz Exploration is in their Cultural Integrity Area, cultural resources, and Settlement Land parcels near Cache Creek.	PDF copy available upon request
Tr'ondëk Hwëch'in Comments	YESAB	Tr'ondëk Hwëch'in noted the Dempster Highway Shoreline Stabilization project was in the boundaries of the Tr'ondëk Hwëch'in Cultural Integrity Area and a key goal of the Tr'ondëk Hwëch'in Final Agreement was to recognize and protect the economic and spiritual relationship between Tr'ondëk Hwëch'in and the land.	PDF copy available upon request
Tr'ondëk Hwëch'in Comments	YESAB	Tr'ondëk Hwëch'in outlined concerns for Dempster Highway Shoreline Stabilization development infringing on treaty rights, use of heritage resources, access to natural vegetation and foods, and impacts to wildlife and habitat. Heritage resource examples included harvesting, migration routes, traplines, medicines, place names/stories, camps/trails/burial sites).	PDF copy available upon request
Weathering Changes: Cultivating Local and Traditional Knowledge of Environmental Change in Tr'ondëk Hwëch'in Traditional Territory	YESAB	Tr'ondëk Hwëch'in discuss approaches and uses of traditional knowledge in environmental assessments. This article includes a Traditional Territory map (p. 441).	PDF copy available upon request
Tr'ondëk Hwëch'in Review of the Dawson Regional Draft Plan	Jstor	Tr'ondëk Hwëch'in noted Eagle Plains includes an important caribou harvesting area and potential for undiscovered archaeological sites/infrastructure related to harvest activities.	PDF copy available upon request
Tr'ondëk Hwëch'in Land Use: Dawson Planning Region	EMR Library	Map of Tr'ondëk Hwëch'in land use area.	PDF copy available upon request

Document Title	Source	Summary	URL (if available)
Vuntut Gwitchin First Nation			
Nanh Kak Ejuk Gweedhaa	Vuntut Gwitchin First Nation	Report of the changes in Vuntut Gwitchin First Nation Traditional Territory informed by traditional knowledge and Vuntut Gwitchin First Nation way of life. Includes trends related to community, weather, human health, insects, heritage, water, plants, animals, birds, and salmon.	PDF copy available upon request
YESAB Request for Information Chance Oil and Gas Eagle Plains Proposal	The Narwhal	Comments from Vuntut Gwitchin First Nation regarding impacts to traditional land use, consideration of culturally significant resources, and inclusion of traditional knowledge regarding wildlife.	PDF copy available upon request
Natural Resource Maps	Government of the Vuntut Gwitchin First Nation	Index of maps showing traditional knowledge of fish and wildlife data.	Vuntut Gwitchin First Nation Government Website (vgfn.ca)
Reconciling Traditional Knowledge, Food Security, and Climate Change	Project Muse	Discusses food security challenges related to traditional harvests of caribou and chinook salmon, and decline in practicing traditional food culture.	PDF copy available upon request
Vah Srigwehdli': The One Who Survived	Gwaandak Theatre and Vuntut Gwitchin Government	Story that exemplifies Gwich'in survival skills, resilience, community, and generosity. Serves as a reminder that climate change is harsh, fish and game are not always plentiful, and there is a growing concern about food security.	PDF copy available upon request

In addition to sharing secondary sources of Traditional Knowledge, Chance invited each potentially affected First Nation to share additional Traditional Knowledge sources to help inform the development of the assessment and Project Proposal. Chance offered to meet and discuss alternative submission options for certain Traditional Knowledge sources, if interested.

Vuntut Gwitchin First Nation provided consent for the use of identified secondary Traditional Knowledge sources and provided additional sources. Interviews with representatives of Vuntut Gwitchin First Nation also provided confirmation of available information about cultural use within their Traditional Territory, including the LSA.

Gwich'in Tribal Council provided consent for the use of identified secondary Traditional Knowledge sources and provided additional sources. Interviews with representatives of Gwich'in Tribal Council also provided confirmation of available information about cultural use within their Traditional Territory, including the LSA.

The First Nation of Na-cho Nyäk Dun did not consent to the inclusion of available Traditional Knowledge and did not participate in the socio-economic interview program. As a result, limited information is available about cultural use for First Nation of Na-cho Nyäk Dun within the LSA.

Tr'ondëk Hwëch'in did not consent to the inclusion of available Traditional Knowledge and did not participate in the socio-economic interview program. As a result, limited information is available about cultural use for Tr'ondëk Hwëch'in within the LSA.

Approved Traditional Knowledge secondary sources were used to inform the understanding of existing socio-economic conditions, the scoping of the socio-economic VESECs, the definition of socio-economic study area boundaries, and the identification of socio-economic Project interactions and effects. The assessment of First Nations Culture and Land and Resource Use in Section 11 of the Project Proposal is constrained by the availability of Traditional Knowledge used to support an understanding of the use of lands and resources by First Nations in the LSA.

Where Traditional Knowledge has not been provided by the First Nations, information about cultural use of the LSA was compiled from publicly available sources such as regional land use plans and other project proposals related to the LSA. Chance recognizes that the absence of Traditional Knowledge relevant to each potentially affected First Nation does not imply that this knowledge and information does not exist, or that the potentially affected First Nations have no cultural land and resource use interests or values associated within the LSA or RSA.

Chance will continue to consult and engage potentially affected First Nations to better understand their preferences around Traditional Knowledge and how it can be applied to the environmental and socio-economic assessment of the Project.

3.3 CONSIDERATION OF ABORIGINAL AND TREATY RIGHTS

Proponent-led consultation is distinct from Crown requirements to consult First Nations (Government of Canada 2003). The Crown has a duty to consult with affected First Nations about projects "and, where appropriate, to accommodate Indigenous groups [when] it considers conduct that might adversely affect potential or established Aboriginal or treaty rights" (Crown-Indigenous Relations and Northern Affairs Canada 2023).

Chance's consultation and engagement activities with potentially affected First Nations and residents of communities designed to meet consultation requirements under sections 3 and 50(3) of the YESAA (Government of Canada 2003) is described in **Section 2** of the Project Proposal. Issues and interests identified through consultation and engagement activities and how that input has informed Project scoping is described in **Table 2-1: Key Feedback Shared from 2014 to the Present** of **Section 2 Consultation and Engagement**.

Issues and interests related to environmental and socio-economic conditions identified through consultation and engagement activities have informed the scoping of VESECs, the definition of study area boundaries, and the identification of Project interactions and effects. Key issues and interests raised include:

- cultural value of the PCH and concern about their decline;
- impacts to wildlife behaviour and habitat that are valued as traditional food and for cultural and spiritual well-being;
- concern about effects to traditional trails and traditional sites related to cultural use areas for trapping and hunting (i.e., moose and caribou);
- increased access to traditional territories and resulting damage to the livelihood of First Nations citizens;
- interest in employment and contract opportunities;
- concern over the capacity of local communities to meet the demand for employment opportunities without further training and funding;
- impacts to the potential visual impacts to the landscape;
- concern about the human land use-related disturbances such as noise, smell, and light and potential mitigations;
- concern related to increased traffic on the Dempster Highway;
- opportunities for involvement in monitoring;
- concerns about Project-related effects to climate change and related impacts to the land and the wildlife on which First Nations depend for food, and ability of to travel and use the land for traditional purposes;
- concern about potential for water contamination (used by land users while on the land);
- concern for potential Project-related effects to water bodies and wetlands from new winter road and permafrost/terrain stability;
- identifying that the landscape is a key cultural value for the First Nations;
- concern about Project access roads and effects to water and fish;
- concern over increased risk of increased ski-doo traffic and access management;
- comment highlighting the importance of upholding objectives from the North Yukon Regional Land Use Plan;
- comment requesting clarification on process for protecting oral history;
- comment highlighting the issue of oil and gas exploration's effect on the quality of Traditional Territory and impact to the livelihood of First Nations; and,
- Further detail on consultation and engagement input is provided in **Section 2 Consultation and Engagement, and Section 11 Socio-Economics**.

4 PERMAFROST AND TERRAIN

Permafrost is ground that remains at or below 0 degrees Celsius (°C) for at least two consecutive years. At a local scale, the presence and thickness of permafrost depend on factors such as air temperature, snow cover, vegetation, and the ground's thermal properties. Above the permafrost is the active layer, a layer of ground that freezes in winter and thaws in summer, playing a crucial role in the movement of water from rainfall and snowmelt. Permafrost is primarily a concern if it contains large quantities of ice; bedrock and coarse gravel may be frozen but tend to have little to no ice, whereas finer sediments, like silt and sand, contain more ice. When these frozen sediments thaw, sediment and water become more mobile. Terrain stability considers geology and soils, inactive and active geomorphological processes, and landform assemblages. Terrain stability plays an important role in terrestrial and aquatic ecosystems, water quantity and quality, land use planning, and natural hazards. The baseline report (**Appendix 4-A Terrain and Permafrost Baseline Report**) describes the current permafrost and terrain stability conditions within the Regional Study Area (RSA); the Exploration Development Suitability (EDS) assessment outlined the baseline report is an important component of the environmental constraints map for the Eagle Plains Exploration Project (Project).

4.1 ASSESSMENT INDICATORS AND ASSESSMENT PARAMETERS

The Project has the potential to interact with permafrost and terrain stability, and the assessment indicators of potential adverse effects are changes to the extent of ground ice (through either changes in ground temperature, active layer thickness, or ice content), and changes that results in ground settlement or mass movement (typically associated with changes to surface drainage or slope morphology). The assessment approach for permafrost is a quantitative approach to permafrost degradation, or aggradation. The assessment approach to terrain stability is a qualitative discussion on terrain instability.

4.2 PROJECT INTERACTIONS AND POTENTIAL EFFECTS

The potential for the Project to interact with and adversely affect permafrost and terrain stability was assessed by systematically reviewing each of the components listed in the Project description (**Table 4-1**). The Project includes several components that have the potential to interact with and adversely permafrost and terrain stability. Each of these components received scores (0 = no interaction; 1 = minor interaction; 2 = substantial interaction) based on the expected magnitude of a potential adverse effect. Only component-effect interactions with a score of 2 are considered in residual adverse effects characterization, whereas lower scores are associated with adverse effects that are small (immeasurable) or negligible.

In general, Project-related activities could degrade (thaw) ice-rich permafrost or destabilize slopes, as well as adversely affect other Valued Environmental and Socio-Economic Components (VESECs). The following is a non-exhaustive list of potential effects pathways:

- Thaw of permafrost, irrespective of its ice content, can alter local water quantity (hydrology) through changes in the availability and capacity of soils (active layer) to store moisture.
- Changes in micro-topography and drainage conditions, through regrading or thermokarst activity, can alter vegetation health, rare plant survival and associated wildlife habitats.

- Unnaturally high rates of delivery of fine-grained sediments into creeks and rivers, in response to accelerated erosion on disturbed slopes, can be detrimental to water quality and fish and aquatic resources.
- Slope instability and/or thermokarst could disturb, or increase the risk of disturbance to, heritage resources or access corridors for hunting, trapping or other land uses.
- Thaw of organic-rich permafrost could accelerate the release of greenhouse gases into the atmosphere beyond rates already naturally occurring due to climate change.

4.2.1 Interactions Table

Eleven of the 14 Project components may interact with permafrost and terrain stability causing potential adverse effects by changes in changes to the extent of ground ice, and changes that results in ground settlement or mass movement. The direct and indirect pathways for potential adverse effects because of the Project components are described in the following sections.

Table 4-1. Expected Interactions Between the Permafrost and Terrain Stability Valued Environmental and Socio-Economic Components and Project Activities, by Type of Potential Effect

Project Component / Activity Subcomponent		Degradation of Permafrost	Aggradation of Permafrost	Terrain Instability
Seismic Exploration	Seismic line construction	2	0	1
	Helipads and staging sites	2	2	2
	Temporary creek crossings	2	0	2
	Seismic recording	0	0	0
Winter Well sites	Pad construction	2	2	2
	Drilling	2	2	0
Mix Bury and Cover Sites		2	2	2
Quarry Sites/ Borrow Pits		2	2	2
Winter Roads/ Trails (Seismic)		2	0	1
Winter Roads (Well Sites)		2	1	1
Main Camp		1	0	0
Secondary Camp		2	2	2
Dempster Highway Use		0	0	0
Airstrip		0	0	0

Notes:
0 = no interaction

1 = minor interaction with VESEC possible, but small immeasurable effect (e.g., possible slight behavioural response, no vegetation effects, no measurable effect on water quality). Designates a summary of effects that are addressed in the effects assessment as a discussion. This rating does not lead into residual effects characterization.

2 = substantial interaction with VESEC, designates a more detailed assessment of potential effects. Carry forward into residual effects characterization.

4.2.2 Degradation of Permafrost

Degradation (or warming) of permafrost through surface disturbances can occur due to flaring, compaction/stripping of organics, snow plowing/piling, or alteration of surface drainage patterns. Permafrost can warm and eventually degrade beneath such surface disturbances (**Figure 4-1**), initiating or exacerbating thermokarst activity in ice-rich terrain. The concentration of surface runoff may increase heat transfer from flowing or pooled water into the comparatively cool ground, thereby slowing annual freeze-back of the active layer. It may also warm and ultimately degrade (thaw) ice-rich permafrost, initiating or exacerbating thermokarst activity.

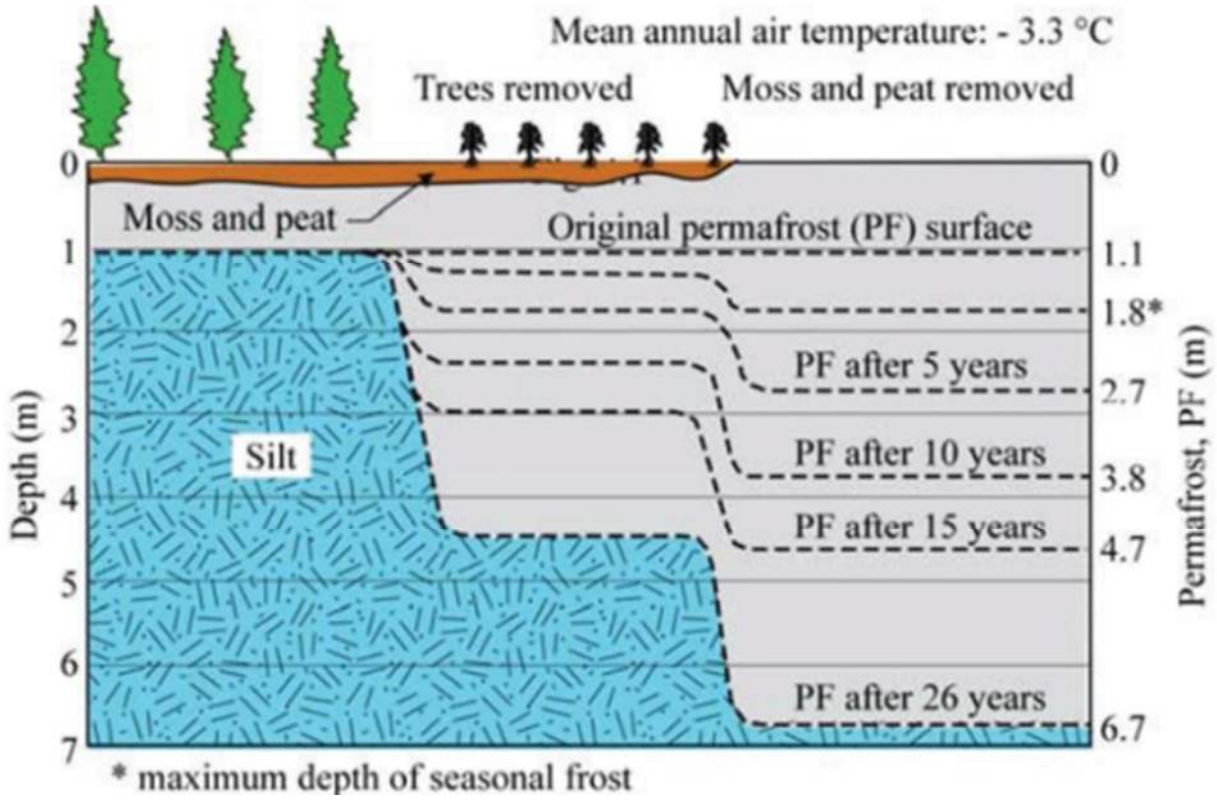

Figure 4-1. Permafrost Degradation (thaw) in Response to Different Surface Conditions: Undisturbed (left), Trees Removed (middle), and Moss and Peat Removed (right) (from Linell (1973), cited by Doré and Zubeck (2008)

4.2.3 Aggradation of Permafrost

Aggradation of permafrost can through placement of thick material in shaded areas with shallow permafrost. Fine-grained material retains moisture and, in the right setting, can gradually draw permafrost upward into it. If on a slope, the mounded permafrost may disrupt natural patterns of water flow through the active layer.

4.2.4 Terrain Instability

Project activities could initiate or exacerbate terrain stability by alteration of slope morphology or surface drainage. The alteration to slope morphology may be a result of oversteepening (cut) or excess weight (fill) on slopes. Reducing the likelihood or magnitude of slope failures may or may not be possible in areas where the hazard cannot be avoided.

In addition, changes in surface runoff patterns, especially where water becomes concentrated (e.g., in ditches and culverts), can increase the potential for slope instability by increasing soil saturation levels and, in turn, reducing associated shear strength. Mass movement may result. The management of surface runoff will be critical on slopes underlain by permafrost; unnatural concentrations can quickly saturate the active layer and reduce its effective shear strength, resulting in active layer detachments, or cause subsidence in ice-moderate or ice-rich settings.

4.3 MITIGATION MEASURES

The Project has a comprehensive set of measures designed to mitigate potential effects on permafrost and terrain stability. Standard mitigation measures to minimize residual effects of the Project on permafrost and terrain stability are described in this section and presented in **Table 4-2**.

Proactive risk mitigation is always preferred, especially in association with thermokarst-related hazards within a changing climate. Once thermokarst is initiated, whether naturally or through anthropogenic disturbance, it is extremely challenging to arrest. In areas where hazard avoidance is not possible or practicable, hazard mitigation measures can accommodate and manage permafrost and terrain stability hazards through design and operating procedures, reducing or eliminating drivers. **Table 4-2** summarizes the mitigation measures proposed to address one or more of the potential adverse effects.

Table 4-2. Mitigation Measures

Mitigation Measure	Potential Adverse Effect
Restrict equipment movement to designated corridors and well sites.	• Degradation (or warming) of permafrost through surface disturbances • Terrain instability due to alteration to slope morphology or surface drainage
Minimizing fire risk through limitation of activities outside of winter season and clearing vegetation in work areas to reduce fuel.	• Degradation (or warming) of permafrost through surface disturbances
Site preparation through careful site selection, which can include site specific assessments or use of buffers around elements at risk.	• Degradation of permafrost through alteration of surface drainage patterns and surface disturbances • Aggradation of permafrost through placement of thick material in shaded area with shallow permafrost

Mitigation Measure	Potential Adverse Effect
	• Terrain instability due to alteration to slope morphology or surface drainage
Limit or modify slope geometry through avoidance of piling or grading within areas designated as sensitive in the EDS.	• Terrain instability due to alteration to slope morphology or surface drainage • Degradation of permafrost through alteration of surface drainage patterns
Minimize and/or avoid excavations in sensitive areas in the EDS.	• Degradation (or warming) of permafrost through surface disturbances • Aggradation of permafrost through placement of thick material in shaded area with shallow permafrost
Management of surface runoff, avoiding ponding and concentrated flow down slopes.	• Degradation of permafrost through alteration of surface drainage patterns • Terrain instability due to alteration to slope morphology or surface drainage
Monitor ground temperature within/near construction areas	• Degradation of permafrost through alteration of surface drainage patterns and surface disturbances • Aggradation of permafrost through placement of thick material in shaded area with shallow permafrost
Preparation for installation of thermoshyphons	• Degradation (or warming) of permafrost through surface disturbances

4.3.1 Avoidance of Hazards

The EDS map from the baseline report (**Appendix 4-A**) provide a means of proactively locating Project infrastructure outside areas of LOW or VERY LOW suitability, to the greatest extent possible. This is expected to avoid potential hazards associated with mass movements, thermokarst, or fluvial processes. Only in localized crossings of such areas, or in cases of more minor disturbance such as that associated with winter seismic survey lines, will Chance use other mitigation means through eliminating, reducing, or managing hazards (**Sections 5.3.2** and **5.3.3**).

4.3.2 Elimination or Reduction of Hazards

Where hazards cannot be reasonably avoided through relocation of Project infrastructure, their drivers will be addressed directly to reduce or eliminate the hazard. Strategies to eliminate or reduce hazards related to permafrost and/or terrain stability include, but are not limited to:

- careful management of surface runoff to avoid unnatural concentration of water (flowing or standing) or saturation of surficial materials, especially in areas of potential instability;
- modification of slope geometry where identified, thereby reducing shear stress and reducing the potential for initiation or unimpeded runout of mass movement;
- implementation of measures to prevent starting wildfires, such as restricting smoking to designated areas and keeping machinery free of vegetation, while being prepared to re-insulate burned areas underlain by permafrost with additional organic material; and,
- implementation of erosion and sediment control measures (i.e., silt fencing or hay bailing) to reduce mobilization of fine-grained sediments and their delivery into sensitive receptors (e.g.,

fish-bearing streams) during Project activities that involve excavation of material (i.e., burrow pits, stockpiles, well pad construction).

4.3.3 Accommodation and Management of Hazards

In many cases, elimination or reduction of hazards through direct manipulation of their drivers is cost-prohibitive and unnecessary. Accommodating some degree of permafrost degradation in the design of Project infrastructure, especially considering the rapidity of responses to climate change, is likely necessary. Specific design, construction and maintenance techniques aimed at maintaining or minimizing change to the ground thermal regime are available for areas where ice-moderate or ice-rich permafrost cannot reasonably be avoided (i.e., installation of thermosphyons). The risks associated with most of the slope- and permafrost-related hazards within the Project area can be successfully mitigated through a variety of strategies of accommodation and management, such as:

- avoiding cuts and ditches wherever possible to limit disturbance to the active layer;
- restricting the movement of equipment used to minimize disturbance to surface organics;
- where possible, avoiding cut-slopes and high fills to limit mass movement potential;
- avoiding concentration and ponding of water to avoid degrading permafrost;
- monitoring ground temperatures within and near construction areas before, during and after construction, as a means of detecting early and addressing any unfavourable trends; and,
- Opportunities to limit and manage the runout of potential slope failures will be considered by Chance where the hazard is likely and unavoidable. Measures exist for controlling the trajectory of the mass movement, such as deflection berms. To help control the runout limits, passive or active measures will be considered individually or in combination during well site selection stage – this is a site-specific assessment.

4.4 EFFECTS CHARACTERIZATION

4.4.1 Approach

Modified from **Table 3-6** in **Section 3 Methods**, **Table 4-3** defines the criteria for the permafrost and terrain stability VESEC. Characterizing the residual adverse effects on permafrost and terrain stability considers the Project's potential effects and the mitigation measures used to minimize those potential effects. Residual effects on the VESEC have each been characterized in terms of magnitude, likelihood, geographic extent, duration, timing, frequency, and reversibility (**Table 4-3**). The significance of all residual effects (after mitigation measures are applied) is assessed collectively to determine the overall residual effect of the Project permafrost and terrain stability. (see **Section 5.5 Significance**).

Table 4-3. Permafrost and Terrain Stability Criteria for Characterizing Residual Effects

Criterion		Rating	Definition
Magnitude		Negligible	No qualitative change from existing conditions, as defined within the exploration development suitability classification in the Permafrost and Terrain baseline report (**Appendix 4-A**).
		Low	The residual effect will be a slight, but measurable change from existing conditions.
		Moderate	The residual effect will be a measurable change from existing conditions but will not affect the sustainability of fish and fish habitat.
		High	The residual effect will be a substantial, measurable change from existing conditions that may affect the sustainability of fish and fish habitat.
Likelihood		Unlikely	A residual effect is not expected, but a residual effect is not impossible.
		Possible	A residual effect may occur but is not likely.
		Probable	A residual effect is likely to occur, but it is not certain.
		Certain	A residual effect will occur.
Geographic Extent		Maximum disturbance footprint	The residual effect is confined to the maximum disturbance footprint.
		Local	The residual effect is confined to the Local Study Area.
		Regional	The residual effect is confined to the Regional Study Area.
		Beyond regional	The residual effect extends beyond the Regional Study Area.
Duration, Frequency and Timing	Duration	Short-term	The residual effect duration is less than a year (e.g., days, months)
		Medium-term	The residual effect duration is more than a year and up to the life of the Project (e.g., 10 years).
		Long-term	The residual effect duration is beyond the life of the Project (e.g., decades).
		Permanent	The residual effect is predicted to be permanent and thus unlikely to recover to existing conditions.
	Frequency	Occasional	The residual effect may occur rarely (e.g., once or a few times over the life of the Project).
		Periodic	The residual effect may occur consistently at regular intervals or associated with temporal events (e.g., during spring freshet, low flows, growing season).
		Continuous	The residual effect may occur all the time.
	Timing	Year-round	The residual effect may occur year-round.
		Seasonal	The residual effect may be confined to a portion of the year.

Criterion	Rating	Definition
Reversibility	Reversible	The residual effect is predicted to be reversible within a clearly defined period.
	Irreversible	The residual effect is predicted to influence the assessment indicator indefinitely.

4.4.2 Residual Effect

Residual effects are those effects remaining after the implementation of all mitigation measures, and therefore are the expected consequences. **Table 4-4** and **Table 4-5** outline the residual effects on permafrost and **Table 4-6** the residual effects on terrain instability.

Table 4-4. Characterization of Residual Effects on Permafrost Degradation

Criterion	Rating	Rationale
Magnitude	Low	Site selection for Project-related activities and infrastructure take into consideration EDS, prioritizing areas where bedrock is at or near surface.
Likelihood	Possible	While mitigation measures can decrease the effects of degradation, they cannot wholly eliminate the likelihood.
Geographic Extent	Maximum disturbance footprint	Permafrost degradation will be limited to the disturbance footprint as it is directly tied to the disturbance activity.
Duration	Medium-term	Field review of previous exploration activities show long-term effects of development on permafrost degradation within the disturbance footprint of these past activities without mitigation measures in place. However, with the implementation of mitigation, it is predicted that Project effects will only last up to the life of the Project before returning to baseline conditions.
Frequency	Periodic	Permafrost is expected to respond non-linearly (non-continuously) to surface disturbance, because maximum degradation is likely in summer with minimal degradation continuing in winter.
Timing	Year-round	Measurable response of permafrost to Project disturbance/activities may not be immediate but would be expected within the first few years, and would be present year-round until returning to baseline after cessation of Project activities
Reversibility	Irreversible	Degraded (thawed) permafrost is unlikely to naturally reform under current climate conditions, especially in recently burned areas, except potentially in shaded valley bottoms.

Table 4-5. Characterization of Residual Effects on Permafrost Aggradation

Criterion	Rating	Rationale
Magnitude	Low	Site selection for Project-related activities and infrastructure will take into consideration the exploration suitability mapping, prioritizing areas where bedrock is at or near surface and those away from streams and rivers for any disturbances beyond winter.
Likelihood	Unlikely	While mitigation measures can significantly decrease the likelihood of change, they cannot wholly eliminate the likelihood.
Geographic Extent	Maximum disturbance footprint	Permafrost degradation is expected to be limited to the disturbance footprint as it is directly tied to the disturbance activity.
Duration	Short-term	Minimal duration for permafrost aggradation is expected, as mitigation measures are easily achievable.
Frequency	Occasional	Minimal frequency for permafrost aggradation is expected, as mitigation measures are easily achievable.
Timing	Seasonal	Changes to active layer thickness through permafrost aggradation are seasonal in nature.
Reversibility	Reversible	Aggraded (expanded) permafrost could, however, return to pre-existing conditions once source of aggradation is removed, as climate continues to warm.

Table 4-6. Characterization of Residual Effects on Terrain Instability

Criterion	Rating	Rationale
Magnitude	Low	Project-related disturbances are surficial, unlikely to initiate or exacerbate any deep-seated instabilities in permafrost, with potential displacements largely limited to the active layer.
Likelihood	Unlikely	As part of Project baseline studies (**Appendix 4-A**), Chance will avoid locations with low EDS for Project-related activity, and thus this residual effect is not expected, though not impossible.
Geographic Extent	Local	In the event of instability, the affected area may extend beyond the disturbance footprint, typically downslope (e.g., active layer detachment) but potentially upslope (e.g., retrogressive thaw flow).
Duration	Medium-term	The greatest impact to slope stability is during an activity and immediately following the activity, before the site re-approaches equilibrium conditions. However, the possibility of thermokarst expansion to continue over a longer period, until ice supplies are exhausted, warrant acknowledgement.
Frequency	Occasional	Following initial mass movement and/or thermokarst subsidence, instability may continue in a discontinuous manner until equilibrium conditions are restored (e.g., failed slopes smooth scarps and revegetate, retrogressive thaw flows exhaust ice supplies).

Criterion	Rating	Rationale
Timing	Year-round	Once instability occurs, it will remain year-round until the conditions that prompted instability are removed or until the residual effect is abated.
Reversibility	Irreversible	Once material has been displaced from a location, whether by mass movement or thermokarst, it cannot be returned to baseline conditions. The area may be filled or regraded but the ecological value (e.g., texture, soil chemistry) will not be the same.

4.5 SIGNIFICANCE

A qualitative aggregation approach was applied to determining the significance of residual effects on permafrost and terrain stability. The magnitude, geographic extent, and reversibility criteria have the most influence on significance. Technical concepts and considerations to inform the determination of significance included:

- Available information on permafrost, terrain stability, and proposed Project activities:
  - Baseline reporting on permafrost and terrain stability was carried out by the Chance Project team (**Appendix 4-A**), based on field investigations (frost probing, shallow drilling, ground temperature monitoring, hand-dug test pitting, visual examination) and detailed surficial geology and exploration development suitability mapping.
  - Relevant research conducted in the Project area or similar settings (see **Section 1**).
- Benchmarks:
  - Baseline ground temperature data since 2021, in a variety of terrain/permafrost settings, will be used as a benchmark for comparison during monitoring during Project lifespan.
  - There are currently no industry-wide benchmarks to define the significance of a residual effect related to permafrost or terrain stability on the environment.
  - Qualitatively, professional accountability recommends minimizing residual effects on the environment where possible (EGBC, 2021, APEGA, 2022, and NAPEG, 2019).
  - Wildfires are historically known to have adverse effects on permafrost and terrain stability; the study area already has a history of wildfire occurrence with likely associated effects.
- Uncertainty:
  - Considered qualitatively, as spatial extent of some proposed Project activities is not defined (i.e., confirmed well site locations), relative to geographic location.

Table 4-7. Definition of Significance

Characterization	Definition
Not Significant	• Absence or minimal change to the environment, • Where any observed changes, if any, fall within the expected range of responsible practices, and • The effect does not worsen existing stressors to a degree that exceeds established benchmarks or acceptable limits.
Significant	• A measurable amount of change, beyond management standards or mitigation measures required to minimize the likelihood and severity of residual effects, and beyond what is reasonably expected by responsible practices of Professional Geologist or Professional Engineer related to activities that are known to affect the natural environment. • The effect exacerbates existing stressors on the environment to levels that exceed expected changes due to climate change.

The location of Project activities relative to the EDS assessment has considerable weight on the anticipated residual effects; the rational for the significance rating expands on this.

Table 4-8. Determination of Significance of Residual Effects on the Valued Environmental and Socio-Economic Components

VESEC	Residual Effect	Significance	Rationale
Permafrost	Low magnitude of change when Project activities align with HIGH or VERY HIGH exploration suitability mapping, over a relatively small footprint, but the result is generally irreversible.	Not Significant	Changes to permafrost are occurring independent of proposed Project activities (i.e., in association with climate change and wildfires). Analysis of active layer thickness (depth to permafrost) and ice content within a 1950s exploration footprint is consistent with minimal degradation when site selection aligns with HIGH or VERY HIGH suitability sites.
Terrain Stability	Low magnitude of instability when Project activities align with HIGH or VERY HIGH exploration development suitability mapping, which is likely to affect a localized area outside of activity footprint and be irreversible.	Not Significant	Less material is available for mobility in HIGH or VERY HIGH suitability areas (i.e., bedrock generally at or near surface). When there is less material available for displacement, the geographical extent that may be affected is limited.

In general, seismic surveys, when done during winter under frozen ground conditions, are not likely to have residual effects on permafrost or terrain stability. Areas classified as low to very low EDS (i.e., ice-rich areas, associated with valley bottoms) may result in larger magnitudes of permafrost degradation and/or terrain instability, potentially affecting a larger geographic extent; however, activities that are currently are not sited (i.e., well site and staging areas) will have site specific assessments conducted prior to development and are planned to occur within moderate to high EDS areas (i.e., wide, rounded ridge tops, shallow bedrock, ice-poor).

4.6 CUMULATIVE EFFECTS ASSESSMENT

4.6.1 Approach

Project-related residual effects on permafrost and terrain stability with the potential to interact with residual cumulative effects of past, present and reasonably foreseeable projects and activities within or extending into the Cumulative Effects Study Area (CESA) are:

- changes to ground ice; and,
- mass movement.

The spatial boundaries of the Cumulative Effects Assessment (CEA) on permafrost and terrain stability are delineated by the CESA as described in **Section 3.1.6.1.1**. Temporal boundaries for assessing cumulative effects encompass past, present, and reasonably foreseeable future activities spanning the Project's lifespan (**Section 1.3.1**).

4.6.2 Cumulative Effects

Cumulative effects to permafrost and terrain stability are expected to generally be limited to the direct area of surface disturbance from anthropogenic footprints (e.g., mineral exploration, oil and gas). The total surface disturbance (area [km²] and percent [%]) for the Project and all other projects and activities within the CESA are presented in **Table 4-9**. In the event of a terrain instability, mass movement may extend beyond the footprints of the various projects and activities, but it would be localized to the immediate area around these footprints.

Present conditions for total surface disturbance include a total area of 62.5 km² (0.6%) disturbed by past and present projects and activities; this is predicted to increase in the future by 1.2 km² (0.0%) following the inclusion of reasonably foreseeable projects and activities. The Project is expected to increase the amount of disturbed area over the existing conditions by a maximum of 69.5 km² (0.6%) within the CESA, resulting in a maximum disturbed area of 133.2 km² (1.2%) when combined with past, present, and reasonably foreseeable projects and activities. These total areas include complete disturbance (i.e., where that disturbance includes maximum ground disturbance inclusive of complete vegetation removal and grubbing) as well as alteration of surface conditions (e.g., removal of taller vegetation, but maintenance of shorter vegetation and ground cover during Low Impact Seismic [LIS]).

Table 4-9. Cumulative Change from Existing and Project-Related Disturbances on Permafrost and Terrain Stability

Cumulative Effect Indicator	Scenario	Cumulative Effects Study Area
Total Surface Disturbance (Footprints)	Present	62.5 km² (0.6%)
	Project	69.1–69.5 km² (0.6)
	Future	1.2 km² (0.0%)
	Total Cumulative Effect	132.8–133.2 km² (1.2%)

The Project area is underlain by continuous permafrost; effects to the above-mentioned indicators can be estimated with changes to active layer thickness (average annual thaw depth to permafrost). Based on previous activities in the area (**Appendix 4-A**), the residual effects of these other past activities have had the effect of reducing the active permafrost layer thickness by approximately 50 centimetres (cm) in areas of direct, complete disturbance. In disturbed areas where vegetation removal is not complete (e.g., LIS) it is expected that the reduction of the active permafrost layer thickness is less. These observed characteristics of developmental effects on permafrost in the RSA were taken into consideration when characterizing the cumulative effects summarized in **Table 4-10**.

Table 4-10. Characterization of Cumulative Effects on Permafrost and Terrain Stability

Criterion		Rating	Rationale
Magnitude		Negligible	The magnitude of cumulative change in permafrost and terrain stability is negligible because it is a <1% change in area at an estimated average difference of 50 cm in active layer thickness when no mitigations effects are in place from existing conditions.
Likelihood		Possible	While mitigation measures can decrease the effects, they cannot wholly eliminate the likelihood. The spacing of activities throughout the CESA decreases the likelihood of cumulative effects.
Geographic Extent		Maximum disturbance footprint	The cumulative effect is expected to remain within the footprint of the relevant projects and activities within the CESA.
Duration, Frequency and Timing	Duration	Permanent	The cumulative effect of changes to ground ice and mass movement is expected to be permanent, extending beyond the life of the Project.
	Frequency	Occasional	Permafrost is expected to respond non-linearly (non-continuously) to surface disturbance, however, following initial mass movement and/or thermokarst subsidence, instability may continue in a discontinuous manner until equilibrium conditions are restored.
	Timing	Year-Round	The effect is expected to occur year-round due to activity within the footprint until Project completion.

Criterion	Rating	Rationale
Reversibility	Irreversible	Changes to active layer thickness are expected to permanent with considered cumulative with climate change effects.

Potential climate change effects could cumulatively interact with residual Project effects and anticipated ongoing and proposed projects and activities effects resulting in changes to permafrost and terrain stability over the 10-year life of the Project. Climate change effects such as increased wildfires, warmer winters, and hotter summers, could increase ground temperature to a point where active layer thickness increases, changing ground ice content and increases susceptibility to mass movement.

4.6.3 Context and Confidence

The Project's environmental context and potential limitations of data and uncertainty associated with the assessment were considered for the assessment of cumulative effects. The ratings and rationale for the context and confidence in accurately quantifying and predicting cumulative effects are described in **Table 4-11**.

Table 4-11. Characterization of Context and Confidence in the Assessment of Cumulative Effects on Permafrost and Terrain Stability

Criterion	Rating	Rationale
Context	Moderate	The assessment of cumulative effects is qualitative at this time, and utilizes reasonable estimates based on current understanding in permafrost science. The Project area is underlain by continuous permafrost, that varies in ground ice content relative to factors, including underlaying material and climate history. To quantify change relative to baseline conditions, a quantitative understanding of climate change effects need to be considered. At this time, climate change models are done at regional scales, decreasing the confidence of models on a Project-specific scale.
Confidence	Moderate	There is moderate confidence in the characterization of the cumulative effect and its persistence. Changes to climate have a significant effect on the assessment indicators, and changes to permafrost and terrain stability can only be quantified through long-term monitoring of a site.

5 WATER RESOURCES

The Water Resources Valued Environmental and Socio-Economic Component (VESEC) assessment considers potential effects from the Eagle Plains Exploration Project (Project) on surface water quality and hydrology in the Regional Study Area (RSA), which represents the spatial extent of water resources potentially affected by the Project. Changes in water quality and hydrology could directly and indirectly affect the aquatic ecosystem, subsequently resulting in effects on fish, aquatic organisms and wildlife that utilize and are supported by these aquatic habitats.

5.1 EXISTING SURFACE WATER QUALITY AND HYDROLOGY

Existing surface water quality and hydrology conditions in the RSA were characterized through baseline studies and analysis of data collected between 2013 and 2020. Baseline studies found that the RSA contains a high number of streams (approximately 1,467, mainly smaller headwater streams), and relatively few waterbodies, none of which are greater than 5 hectare (ha). The major drainages in the RSA include the Porcupine and Peel River watersheds, with the subdrainages of the Eagle and Whitestone rivers entering the Porcupine drainage and the Ogilvie River entering the Peel drainage (**Appendix 5-A Surface Water Quality and Hydrology Baseline**).

Water quality baseline surveys found circumneutral to slightly acidic pH, brown stained water within the RSA. Nutrient concentrations are generally low to moderate, while total phosphorus concentrations indicate that streams are oligotrophic to mesotrophic (**Appendix 5-A**). Melting permafrost results in slumping banks that deposit material into the water column creating variable turbidity and total suspended sediment concentrations. Total metals including aluminum, cadmium, copper, iron, and manganese are present throughout the RSA at concentrations that exceed the Canadian Council of Ministers of the Environment guidelines for protection of freshwater aquatic life (CCME-FAL, CCME 2007).

Other metals were present at concentrations above the CCME-FAL in samples from each watershed area, including arsenic from Chance and Dalglish Creek sites, and selenium from McParlon, Eagle and Dalglish creek sites. Volatile organic carbons were not measured at or above laboratory detection limits at any of the sample locations in the baseline assessment (**Appendix 5-A**). Some Polycyclic Aromatic Hydrocarbons (PAHs) associated with naturally occurring oil and gas deposits and by-products of forest fires were measured in water samples from within the RSA, including naphthalene, biphenyl, phenanthrene, and retene.

Annual discharge in streams in the RSA watersheds is snowmelt driven, with peak flows during the spring and low flows during the winter (**Appendix 5-A**). Watercourses in active permafrost regions, like that of the RSA, range from permanent flow to intermittent flow, which are seasonally timed. The lower order streams are more likely to be seasonally intermittent as inputs from precipitation decrease as rain transitions to snow, and baseflows are reduced as shallow permafrost re-freezes. In the case of the smaller streams, the channel may fully freeze in early winter. Additionally, ice build-up in watercourses alters flow behaviour through the formation of ice in the channel as well as changes in flow dynamics in flowing streams of all sizes, and this effect occurs naturally from the beginning of freeze-up until spring thaw is complete.

5.2 ASSESSMENT INDICATORS AND ASSESSMENT PARAMETERS

The Water VESEC assessment indicators are surface water quality and hydrology. The approach for assessing the Project's effects on the surface water quality and hydrology indicators was to qualitatively evaluate the potential changes on sedimentation and total suspended solids (TSS), changes in contaminant and nutrient influxes, changes in thermal regimes and changes in flows and water levels.

5.3 PROJECT INTERACTIONS AND POTENTIAL EFFECTS

5.3.1 Project Interactions

Project-related activities identified as having the potential to interact with water resources include: seismic and drilling exploration, extended flow test (EFT), well maintenance, winter access roads, construction and operation of Mix Bury Cover (MBC) sump, Central Processing Facility (CPF), airstrip, water withdrawals, transportation and camp (**Table 5-1**).

The direct and indirect pathways for potential effects (sedimentation, contaminant and nutrient influxes, thermal changes and reduced flow and water levels) on surface water quality and hydrology indicators are discussed qualitatively in the sections below.

Table 5-1. Expected Interactions Between the Water Valued Environmental and Socio-Economic Component and Project Activities, by Type of Potential Effect

Project Component / Activity	Sedimentation	Contaminant and Nutrient Influxes	Thermal Changes	Reduced Flow and Water Levels
Engagement	0	0	0	0
Seismic Exploration	2	2	2	2
Drilling Exploration	2	2	2	2
Extended Flow Test (EFT)	2	2	2	2
Well Maintenance (Workovers)	0	0	0	0
Winter Access Roads	2	2	2	2
Mix Bury Cover (MBC) Construction and Operation	0	2	0	2
Central Processing Facility (CPF)	2	2	2	2
Airstrip	0	2	0	0
Water Withdrawal	2	2	2	2
Transportation	0	0	0	0
Camp	0	2	2	2
Reclamation and Closure	0	2	0	0

Notes:
0 = no interaction

1 = minor interaction with surface water quality and hydrology is possible, but small immeasurable effect. Designates a summary of effects addressed in the effects assessment as a discussion. This rating does not lead into residual effects characterization.
2 = substantial interaction with surface water quality and hydrology, designates a more detailed assessment of potential effects. Carried forward into residual effects characterization.

5.3.2 Increased Sedimentation

The Eagle Plains Basin has few watercourses of any substantial size. Most watercourse freeze to bottom in winter, and no major watercourses (i.e., those streams or rivers that either freeze to the bottom or the flow of water is too great to sustain a snow fill crossing) will require watercourse crossings to support Project activities. Project activities that may occur adjacent to watercourses, or require crossings of minor watercourses, have the potential to, if unmitigated, increase sediment concentrations, as TSS, through the potential erosion of unstable banks from works (e.g., removal of riparian trees to accommodate temporary stream crossings, seismic lines, seismic recording, and use of mobile equipment). Increased TSS may, in turn, result in an increase in concentrations of total metals bound to the particulate matter. As a result of increased TSS and contaminants, aquatic organisms can be adversely affected chronically (e.g., growth inhibition, reproductive disorders) or acutely (e.g., mortality).

5.3.3 Contaminant and Nutrient Influxes

Contaminant concentrations may directly increase in the RSA (e.g., accidental spills or leaks, seismic recording or indirectly (e.g., leaching of nitrogen from seismic recording, increased metal concentrations due to increased runoff). During seismic recording, by-products from the detonation of explosives may include compounds that can be toxic to fish and other aquatic biota. The specific processes leading to the release of nitrogen and the distribution of water-soluble nitrogen species to the environment are difficult to quantify and predict, but they are not expected to be substantial contributions to Project effects.

Wastewater resulting from camp activities could result in increased contaminants of concern and thermal changes in surface waters if it were to be discharged into a local stream. However, all wastewater and sewage will be collected and treated on-site before being released, with appropriate authorization, as clean water back into the environmentand is therefore not considered a potential effect pathway in this assessment.

5.3.4 Thermal Changes

Reduced water levels and reduction in baseflow at the water withdrawal location, as well as removal of riparian vegetation for the construction of seismic lines and temporary creek crossings can indirectly affect water temperatures. Lower water volume and the loss of shade make the streams (particularly smaller, low flowing streams), more susceptible to diurnal temperature fluctuations as well as seasonal climate variations resulting in potential warming effects during spring through early fall, when air temperatures tend to be greater than water temperatures, and a cooling effect during winter, when air temperatures tend to be colder than water temperatures. Thermal changes can result in a wide range of effects on the aquatic ecosystem by influencing oxygen levels, bacterial activity, chemical reactions, algae growth, fish physiology and species composition.

5.3.5 Reduced Flow and Water Levels

The Project will require fresh water for several activities, including the camp, winter road construction, well pad construction, well drilling, and well completion. Water withdrawals are proposed to occur year-round from the Eagle River, Ogilvie River, and Whitestone River, and seasonal extraction from Glacier Creek. The majority of water withdrawal is expected to occur in the winter.

Water withdrawals for Project works can result in changes in both surface water quality and hydrology. At the withdrawal point, water levels and flow are expected to be directly affected (reduced). The removal of source water can alter the natural processes of the channel (such as cleansing or flushing) as well as the natural recharge rates. Ice bridge construction for temporary stream crossings could contribute to the impediment of flows which are already naturally altered by ice build up in the RSA from the beginning of freeze-up until spring thaw is complete, though the majority of creeks and waterbodies in the Project area are completely frozen in the winter. A reduction in depth and baseflow can contribute to loss of available habitat (further discussed in the Fish VESEC, Project Interactions and Potential Effects) and overall degradation of water quality, lead to increased water temperature, increase in sediment oxygen demand (thus lowering dissolved oxygen levels) and alter the general chemistry of the water (as discussed above).

5.4 MITIGATION MEASURES

The Project will implement mitigation measures that are specific, measurable, verifiable and achievable in nature to avoid and minimize the potential for adverse effects on water in the RSA. The Project's design to conduct activities in stages, focusing on one area of the RSA at a time and completing most of the work during winter (November to April) will reduce the magnitude, duration, and extent of the Project's potential effects on the overall environment.

As a key mitigation measure, Project design is being done in consideration of the locations of waterbodies and their surrounding riparian areas through the environmental constraints mapping. The Yukon Energy, Mines and Resources's Forest Management Branch has established management guidelines for forest operations near streams, lakes, and wetlands. Although these guidelines were developed specifically for forestry, they are commonly applied to other resource developments in the territory as the best available information. The objectives of the guidelines are to conserve the integrity of water quality for fish, riparian habitat for wildlife, and hydrology.

The primary tool used to meet the management objectives is designation of a Riparian Management Area (RMA) around each water feature. Project features will, wherever practicable and with the exception of seismic features, be located outside the RMA. The RMA includes two components, a Reserve Zone (RZ) and a Management Zone (MZ). The size of the RZ and MZ vary depending on the size of the stream and the presence of fish, and both zones have acceptable size ranges. The RMA sizes applied to the Project's environmental constraints map are outlined in **Table 5-2** and **Table 5-3** for streams and lakes, respectively. Since widths are not known for all streams in the RSA, the RMA widths were attributed based on stream order, considering the average stream widths for each order that were measured in the field.

Table 5-2. Riparian Management Area Buffers for Streams in Eagle Plains Regional Study Area

Stream Order	Width (m; ± SE*)	Reserve Zone (m)	Management Zone (m)	Total Riparian Management Area (m)
1	1.91 ± 0.25	40	40	80
2	3.36 ± 0.30	40	60	100
3	4.26 ± 0.42	40	60	100
4	10.09 ± 0.31	50	70	120

Table 5-4 outlines mitigation that will be incorporated into the Project to address potential adverse effects to Water Resources.

Table 5-4. Mitigation Measures Relevant to Water and the Eagle Plains Exploration Project

Mitigation Measure	Potential Effect Addressed by Mitigation
Winter road construction, which will have the greatest water requirements, will primarily occur in November, December, and, to a lesser degree, January to reduce water withdrawal needs during the lowest flow periods (February and March)	• Reduced flow and water levels • Thermal changes
All wastewater and sewage will be collected in tanks approved by the Canadian Standards Association, treated on-site, then released as clean water back into the environment	• Contaminant and nutrient influxes • Thermal changes
Minimize Project activities in and near aquatic areas	• Sedimentation • Contaminant and nutrient influxes • Thermal changes
With the exception of seismic lines, Project features will be located outside the RMA (and particularly the RMZ), to the extent practicable. Overlap with a small extent of the RMZ is permissible where operations cannot completely avoid them.	• Sedimentation • Contaminant and nutrient influxes • Thermal changes

Mitigation Measure	Potential Effect Addressed by Mitigation
For seismic activities, with the exception of mechanical watercourse crossings, restrict all mechanical equipment 55 m away from the bank edge	• Sedimentation • Contaminant and nutrient influxes • Thermal changes
For mechanical seismic watercourse crossings, employ the following crossing site selection criteria: • areas with natural clearings, where available; • shallow banks • good bank stability; • areas with shallow water (e.g., not on bends in the river); • areas with 90 degrees access to the river; and • creek location that freezes to bottom.	• Sedimentation • Contaminant and nutrient influxes • Thermal changes
Minimize the number of stream crossings, especially on 3rd order and higher streams.	• Sedimentation • Contaminant and nutrient influxes • Thermal changes
Where stream crossings occur, align the road to minimize the extent of the RMA that is affected	• Sedimentation • Contaminant and nutrient influxes • Thermal changes
Concentrate Project activities in the winter	• Sedimentation • Contaminant and nutrient influxes • Thermal changes
If concrete works are required near streams, avoid concrete works when precipitation events are anticipated within 72 hours and the work cannot be contained	• Contaminant and nutrient influxes
Avoid concrete spillage	• Contaminant and nutrient influxes
Isolate concrete and concrete wash from the aquatic and riparian environment	• Contaminant and nutrient influxes
Construct all concrete forms so that they are properly sealed (e.g., proper sealed and locked chutes, hose, and hose connections)	• Contaminant and nutrient influxes
Maintain a carbon dioxide (CO_2) tank with a regulator, hose and gas diffuser on site to neutralize pH levels if a concrete spill to water occurs	• Contaminant and nutrient influxes
Isolate and hold any water that contacts uncured or partly cured concrete until the pH is less than 9.0 (BC freshwater quality guideline for pH is 6.5 to 9.0) (British Columbia Ministry of Environment and Climate Change Strategy [BC MECCS])	• Contaminant and nutrient influxes

Mitigation Measure	Potential Effect Addressed by Mitigation
All mobile equipment brought on site will be clean, free of leaks, excess oil and grease, and in good working order	• Sedimentation • Contaminant and nutrient influxes
All mobile equipment will be checked every morning for leaks and good working order	• Contaminant and nutrient influxes
Hydraulic machinery, if required, will use environmentally sensitive hydraulic fluids that are non-toxic to aquatic life and are readily or inherently biodegradable	• Contaminant and nutrient influxes
Refuelling, fuel stockpiling, and maintenance of mobile equipment will be limited to designated areas on level, impermeable surface areas at least 30 m away from water	• Contaminant and nutrient influxes
All refuelling will occur using funnels, pads, and drip pans in place	• Contaminant and nutrient influxes
Fuels, lubricants, and chemicals will be stored appropriately on site, with proper controls to prevent the release of deleterious substances, in a designated area at least 30 m away from water	• Contaminant and nutrient influxes
Properly sized oil drip pans will be placed under all equipment and vehicles left on site	• Contaminant and nutrient influxes
Develop a Spill Response Plan as part of the Environmental Management Plan	• Contaminant and nutrient influxes
The Spill Response Plan will (1) include a list of spill response equipment that will be present on site, (2) assign implementation and monitoring roles, and (3) require site personnel to have reviewed the plan, understand their roles and responsibilities, and are properly trained and equipped to conduct spill response activities	• Contaminant and nutrient influxes
Identify high-risk locations where spills are probable and maintain spill kits, capable of handling the largest potential spill through the duration of the Project, at these locations	• Contaminant and nutrient influxes
Locate Personal Protective Equipment (PPE) at the top of the spill kit to ensure easy access for the spill responder	• Contaminant and nutrient influxes
Keep spill kits closed with a safety seal affixed to indicate if the kit has been used or tampered with	• Contaminant and nutrient influxes
Respond immediately to all spills in accordance with plan	• Contaminant and nutrient influxes

Mitigation Measure	Potential Effect Addressed by Mitigation
If any accidental spills occur, they shall be immediately contained, cleaned up and reported (if reportable amount or type).	• Contaminant and nutrient influxes
Winter access road construction will follow the DFO Code of practice: Ice bridges and snow fills (Fisheries and Oceans Canada 2023)	• Sedimentation • Contaminant and nutrient influxes • Thermal changes
Locate a temporary crossing site where the watercourse is straight, banks are stable and where approaches have low slopes	• Sedimentation • Thermal changes
Operate vehicles and machinery in a manner that minimizes disturbance to the watercourse bed and banks	• Sedimentation
Do not leave logs or woody debris within the watercourse or on the banks where they can wash back into the watercourse	• Sedimentation
If logs are used for watercourse crossing construction, ensure that the logs are clean and securely bound together, and are removed before the spring freshet	• Sedimentation
Place a v-notch in centre of the ice bridge when crossing season is over (and it is safe to do so) to prevent blocking water flow and thus minimize channel erosion and flooding	• Sedimentation
Use only clean materials (i.e., water, ice, snow) to construct ice bridge	• Sedimentation
Remove compacted snow from the snow fills prior to the spring freshet	• Reduced flow and water levels • Contaminant and nutrient influxes
Water withdraw will not exceed 10% of the actual (instantaneous) flow	• Reduced flow and water levels • Thermal changes
Develop an Erosion and Sediment Control Plan as part of the Environmental Management Plan	• Sedimentation
Activities in the riparian zone will follow the DFO *Code of Practice: Ice bridges and snow fills*. (Fisheries and Oceans Canada 2023)	• Sedimentation • Contaminant and nutrient influxes • Thermal changes
Use existing trails, roads, access points or cut lines wherever possible	• Sedimentation • Thermal changes
Limit vegetation removal, pruning and grubbing to the area required for accessing the site of the works, undertakings and activities	• Sedimentation • Thermal changes

Mitigation Measure	Potential Effect Addressed by Mitigation
Construct roads, access points and approaches perpendicular to the watercourse if a new access point is required to reach the watercourse	• Sedimentation • Thermal changes
Construct approaches using clean compacted snow and ice to a sufficient depth to protect the banks of the watercourse	• Sedimentation
Restore the banks and riparian vegetation affected by the works, undertakings, and activities to their natural state	• Sedimentation • Thermal changes
Do not use ammonium nitrate-fuel oil mixtures	• Contaminant and nutrient influxes

5.5 EFFECTS CHARACTERIZATION

5.5.1 Approach

The residual effects characterization for the Water VESEC considers the Project's potential effects on surface water quality and hydrology indicators and the mitigation measures used to minimize those effects. The spatial boundary of effects characterization for Water was the RSA. Residual effects on surface water quality and hydrology have each been characterized in terms of magnitude, likelihood, geographic extent, duration, timing, frequency, and reversibility (**Table 5-5**). Determining residual effects on surface water quality and hydrology considered the context of the highest development (conforms to Regional Land Use Plans) and the confidence in accurately quantifying and predicting those residual effects. The significance of all residual effects (after mitigation measures are applied) is assessed collectively to determine the overall residual effect of the Project on the Water VESEC.

Table 5-5. Definitions of Effects Criteria Classification for the Assessment of Surface Water Quality and Hydrology in the Eagle Plains Exploration Project

Criterion	Rating	Definition
Magnitude	Negligible	No measurable change from existing conditions. **This corresponds to a less than (<)1% change in an assessment indicator.**
	Low	The residual effect will be a slight, but measurable change from existing conditions. **This corresponds to a 1–10 percent (%) change in an assessment indicator.**
	Moderate	The residual effect will be a measurable change from existing conditions but will not affect the sustainability of surface water and hydrology. **This corresponds to a 11–35% change in an assessment indicator.**
	High	The residual effect will be a substantial, measurable change from existing conditions that may affect the sustainability of surface water quality and hydrology. **This corresponds to a greater than (>)35% change in an assessment indicator.**

Criterion		Rating	Definition
Likelihood		Unlikely	A residual effect is not expected, but a residual effect is not impossible.
		Possible	A residual effect may occur but is not likely.
		Probable	A residual effect is likely to occur, but it is not certain.
		Certain	A residual effect will occur.
Geographic Extent		Maximum disturbance footprint	The residual effect is confined to the maximum disturbance footprint.
		Local	The residual effect is confined to the Local Study Area (LSA).
		Regional	The residual effect is confined to the RSA.
		Beyond regional	The residual effect extends beyond the RSA.
Duration, Frequency and Timing	Duration	Short-term	The residual effect duration is less than a year (e.g., days, months)
		Medium-term	The residual effect duration is more than a year and up to the life of the Project (e.g., years).
		Long-term	The residual effect duration is beyond the life of the Project (e.g., decades).
		Permanent	The residual effect is predicted to be permanent and thus unlikely to recover to existing conditions.
	Frequency	Occasional	The residual effect may occur rarely (e.g., once or a few times over the life of the Project).
		Periodic	The residual effect may occur consistently at regular intervals or associated with temporal events (e.g., during spring freshet, low flows, growing season).
		Continuous	The residual effect may occur all the time.
	Timing	Year-round	The residual effect may occur year-round.
		Seasonal	The residual effect may be confined to a portion of the year.
Reversibility		Reversible	The residual effect is predicted to be reversible within a clearly defined period.
		Irreversible	The residual effect is predicted to influence the assessment indicator indefinitely.

5.5.2 Increased Sedimentation

Table 5-6 presents the characterization of residual adverse effects for sedimentation and TSS. Provided the implementation of all mitigation measures in the previous section is successful, the residual adverse effect (as an increase in sedimentation and TSS) is expected to be of negligible. Any changes in sedimentation and TSS would be confined to the RSA. The duration of the effect is expected to be long term, with re-establishment of any riparian (after riparian vegetation and streambank stabilization is re-established). Sedimentation and increased TSS could occur periodically depending on the Project activities

and/or the season (e.g., increased streambank disturbances during exploration, increased runoff during spring freshet). Changes to sedimentation and TSS are expected to be reversible in the long term (particularly once riparian vegetation re-establishes).

Table 5-6. Characterization of Residual Effects on Sedimentation and Total Suspended Solids

Criterion		Rating	Rationale
Magnitude		Negligible	With the implementation of mitigation, changes in sedimentation and TSS are expected to be negligible, as mitigation is expected to minimize potential changes to water resources due to increased sedimentation.
Likelihood		Possible	Changes in sedimentation and TSS are possible but not likely.
Geographic Extent		Regional	Given stream connectivity and plans to explore throughout the RSA, any change in sedimentation and TSS would occur to the extent of the RSA.
Duration, Frequency and Timing	Duration	Medium-term to long-term	Riparian vegetation re-establishment, and therefore streambank stabilization will take years, during which there could be continued potential for increased sedimentation and TSS (long-term).
	Frequency	Periodic	Sedimentation and TSS would be associated with temporal events, such as during spring freshet.
	Timing	Seasonal	Sedimentation and TSS will be associated with periods of high flows (e.g., spring freshet).
Reversibility		Reversible	Changes in sedimentation and TSS are expected to be reversible in the long term (particularly once riparian vegetation fully re-establishes).

5.5.2.1 Context and Confidence

Determining residual sedimentation and TSS effects on Water Resources considered the context of Regional Land Use Planning and the confidence in accurately quantifying and predicting those effects (**Table 5-7**). Any residual sedimentation and TSS effects would be restricted to periodic events, are considered reversible and low in magnitude. With the implementation of all mitigation measures and protection plans listed in **Section 5.3** and **Table 5-4.** The confidence rating is high. (**Table 5-7**).

Table 5-7. Rating and Rationale for Context and Confidence

Criterion	Rating	Rationale
Context	Highest Development	The RSA is within Land Management Unit IV zones of the North Yukon and Peel Regional Land Use Plans, which are areas zoned for the highest level of development. The Project activities are consistent with the integrated resource management objectives of the LUPs.
Confidence	High	High confidence (low uncertainty) in the ability to characterize any change in sedimentation and TSS, i.e., few knowledge gaps, understanding of mitigation efficacy.

5.5.3 Contaminant and Nutrient Influxes

Table 5-8 presents the characterization of residual adverse effects for contaminant and nutrient influxes. Provided the implementation of all mitigation measures in the previous section, a negligible residual adverse effect is predicted for the Project. Any residual effect would be confined to the RSA. Any residual effect would be of for the medium-term (full exploration period of the Project). The frequency and timing of any residual effect is expected to be occasional and year-round. If a residual effect were to occur, changes to contaminant and nutrient influxes should be reversible in the long term.

Table 5-8. Characterization of Residual Effects on Contaminant and Nutrient Influxes

Criterion		Rating	Rationale
Magnitude		Negligible	With the incorporation of mitigation, changes to contaminant and nutrient influxes are expected to be negligible. Mitigation measures are expected to minimize changes in contaminant and nutrient influxes. Design features and management practices will mitigate for the risk of spills and mitigate the risk of any spills from reaching waterbodies, watercourses, or groundwater.
Likelihood		Possible	Mitigation measures are expected to minimize the likelihood of changes from contaminant and nutrient influxes.
Geographic Extent		Regional	Any change from contaminant and nutrient influxes would be limited to the RSA.
Duration, Frequency and Timing	Duration	Medium-term	The risk of a change from contaminant and nutrient influxes are predicted to remain throughout the full exploration period of the Project (medium-term).
	Frequency	Occasional	Contaminant and nutrient influxes are expected to be rare.
	Timing	Year-round	Contaminant and nutrient influxes, though of low likelihood, may occur year-round, associated with run-off from exploration activities or leaching from seismic activities.
Reversibility		Reversible	Changes to contaminant and nutrient influxes are expected to be reversible in the long term.

5.5.3.1 Context and Confidence

With the implementation of mitigation measures and protection plans listed in **Section 5.3** and **Table 5-4**, the confidence in the predicted residual effect is high (**Table 5-9**).

Table 5-9. Rating and Rationale for Context and Confidence

Criterion	Rating	Rationale
Context	Highest Development	The RSA is within Land Management Unit IV zones of the North Yukon and Peel Regional Land Use Plans, which are areas zoned for the highest level of development. The Project activities are consistent with the integrated resource management objectives of the LUPs.
Confidence	High	High confidence (low uncertainty) in the ability to characterize any change in contaminant and nutrient influxes, i.e., few knowledge gaps, understanding of mitigation efficacy.

5.5.4 Thermal Changes

Table 5-10 presents the characterization of residual adverse effects for thermal changes. Provided the implementation of all mitigation measures in the previous section, a negligible residual adverse effect (as changes to thermal regimes) is predicted for the Project, as very small portions of streams are predicted to be affected. Any residual effect resulting from low water volume and loss of shade would be confined to the RSA. Any residual effect as changes in thermal regimes may be long-term (until riparian vegetation is re-established) in duration. The frequency will be periodic and seasonal (e.g., small streams with reduced flows are more susceptible to diurnal and seasonal temperature fluctuations). If a residual effect were to occur, changes to thermal regimes should be reversible in the long term (particularly once water withdrawals cease and riparian vegetation re-establishes).

Table 5-10. Characterization of Residual Effects on Thermal Changes

Criterion		Rating	Rationale
Magnitude		Negligible	Changes to thermal regimes are expected to be negligible (i.e., very small portion of streams would be affected). Mitigation measures are expected to minimize thermal changes to water.
Likelihood		Possible	Mitigation measures are expected to minimize the likelihood of thermal regime changes.
Geographic Extent		Regional	Any thermal regime changes would be limited to the RSA.
Duration, Frequency and Timing	Duration	Long-term	Changes to thermal regimes may be long-term (recover to baseline), as it will take time for riparian cover to re-establish.
	Frequency	Periodic	Thermal regime changes would mostly be associated with temporal events (e.g., low flows, seasonal temperature extremes).
	Timing	Seasonal	Thermal regime changes will be associated with seasonal variations.
Reversibility		Reversible	Thermal regime changes are expected to be reversible in the long term (particularly once water withdrawals cease and riparian vegetation re-establishes).

5.5.4.1 Context and Confidence

Any residual effect for thermal regime changes would be periodic, are considered reversible and low in magnitude. With the implementation of all mitigation measures and protection plans listed in **Section 5.4**, the confidence rating is high (**Table 5-11**).

Table 5-11. Rating and Rationale for Context and Confidence

Criterion	Rating	Rationale
Context	Highest Development	The RSA is within Land Management Unit IV zones of the North Yukon and Peel Regional Land Use Plans, which are areas zoned for the highest level of development. The Project activities are consistent with the integrated resource management objectives of the LUPs.
Confidence	High	High confidence (low uncertainty) in the ability to characterize changes to thermal regimes, i.e., few knowledge gaps, understanding of mitigation efficacy.

5.5.5 Reduced Flows and Water Levels

Table 5-12 presents the characterization of residual adverse effects for flows and water levels. Accounting for uncertainty related to the quantitative data available, taking into account the precautionary principle, and provided the implementation of all mitigation measures in the previous section, a low magnitude residual adverse effect (as changes to flows and water levels) is predicted. Any residual effect (e.g., altered natural channel processes) would be confined to the RSA, and will be medium-term (full exploration period of the Project) in duration. Any residual effect to flows and water levels will be periodic (primarily during water withdrawal) and year-round, though the majority of water withdrawal will occur in the winter. Changes to flows and water levels should be reversible in the long term (once water withdrawals cease).

Table 5-12. Characterization of Residual Effects on Flows and Water Levels

Criterion		Rating	Rationale
Magnitude		Low	Changes to flows and water levels will be low magnitude (i.e., withdrawals will not exceed 10% of instantaneous flow).
Likelihood		Probable	The residual effect is likely to occur due to periodic water withdrawals to support Project activities.
Geographic Extent		Regional	Any change in flows and water levels would be limited to the RSA.
Duration, Frequency and Timing	Duration	Medium-term	The duration of effects on flows and water levels will be medium-term (i.e., expected to remain for the duration of the Project).
	Frequency	Periodic	Changes to flows and water levels would be associated with periodic withdrawal of water for winter road development, well pad development, and camp operations.

Criterion		Rating	Rationale
	Timing	Year-round	Changes to flows and water levels are expected to be year-round, with the majority of water withdrawals occurring in the winter.
Reversibility		Reversible	Changes to flows and water levels are reversible once water withdrawals cease.

5.5.5.1 Context and Confidence

Due to the uncertainty associated with data limitations and related limitations in quantitatively assessing Project effects, the confidence in the assessment of residual effects on flows and water levels is moderate (**Table 5-13**).

Table 5-13. Rating and Rationale for Context and Confidence

Criterion	Rating	Rationale
Context	Highest Development	The RSA is within Land Management Unit IV zones of the North Yukon and Peel Regional Land Use Plans, which are areas zoned for the highest level of development. The Project activities are consistent with the integrated resource management objectives of the LUPs.
Confidence	Moderate	Some limitations exist with availability of data to characterize and understand existing flow regimes in the RSA, and how those will be affected by the Project. However, based on data available and the anticipated effectiveness of Project mitigation there is moderate confidence in the prediction of residual effects to flows and water levels.

5.6 SIGNIFICANCE

The Water VESEC assessment considered the magnitude, likelihood, geographic extent, frequency, duration, and reversibility to determine if the Project could result in residual effects on surface water quality and hydrology. A weight of evidence approach and professional judgement were used to provide a qualitative classification for determining the significance of residual effects from the Project on surface water quality and hydrology, as defined in **Table 5-14**.

Table 5-14. Determination of Significance

Characterization	Definition
Not Significant	Residual effects do not meet the threshold of significant, defined below.
Significant	Residual effects have high magnitude; regional or beyond regional geographic extent; duration is long-term or permanent; and occur at all frequencies. Residual effects on Water Resources under this definition are considered consequential and potentially irreversible. It's anticipated that, as a result of these effects, the ability to meet land and resource management plan objectives is impaired.

The Project is not expected to substantially affect surface water quality and hydrology. Confidence is moderate to high in the efficacy of management standards and mitigation measures to minimize the likelihood of any residual effects. Changes in sedimentation and TSS, contaminant and nutrient influxes,

thermal regimes and flow and water levels are possible but expected to be negligible to low magnitude, confined to the RSA and in many cases be associated with seasonal events (i.e., increased runoff during spring freshet). The potential for a residual effect to occur to the Water VESEC will be medium-term (throughout the exploration period of the Project) to long-term. Once water withdrawals end, normal flow regimes would immediately re-establish (medium-term), however riparian vegetation re-establishment, and therefore streambank stabilization will take years, during which there could be small but continued (long-term) effects to water quality (e.g., sediment and nutrient inputs, effects to water temperature, etc.). All residual effects are predicted to be reversible and are not likely to persist once Project activities are completed. Therefore, the collective residual effects on Water Resources from all potential sources (sedimentation/TSS, contaminants and nutrient influxes, thermal changes and flows and water levels) are **not significant.**

5.7 FOLLOW-UP MONITORING

To address any uncertainty in residual effects predictions for flow and water levels, and to support and assess the effectiveness of the mitigation measures outlined above, the following monitoring programs will be completed by Chance as part of the Project:

- implement water quality monitoring as part of the Environmental Management/Monitoring Plan (EMP) and Erosion and Sediment Control Plan (ESC) plans;
- develop a flow monitoring program to collect flow measurements at the point(s) of withdraw to monitor discharge and support a determination of the 10% actual (instantaneous) flow. The flow measurements will be collected at intervals appropriate for characterizing baseflow recession during low flow periods, and are expected to be collected more frequently during the first couple of years of the Project; and,
- develop a trigger-response plan to reduce water withdrawals should the instantaneous monitoring data indicate unacceptable direct hydrologic effects (e.g., flows below 10% instantaneous flows) or indirect effects (e.g. increased channel erosion).

5.8 CUMULATIVE EFFECTS ASSESSMENT

Project-related residual effect with the potential to interact cumulatively with the residual effects of projects and activities identified within or extending into the cumulative effects study area (CESA) included changes to water quantity (flow reductions).

The spatial boundaries of the CEA for water were described in **Section 3** and activities outside the CESA but with potential effects within this area were also included in this assessment. Temporal boundaries for assessing cumulative effects encompass past, present, and reasonably foreseeable future activities spanning the Project's lifespan (**Section 1**).

5.8.1 Cumulative Effects

Cumulative effects to surface water flows are expected to generally be limited to water bodies with multiple sources of water withdrawals (e.g. municipal and industrial licenced water diversion points, in-stream alternations of flow). Activities with potential to reduce flows can only be qualitatively assessed for cumulative effects because data on volumes and durations of water use are not available for all water use,

and volumes of withdrawal for the project will be determined based on 10% of the instantaneous flows which will be determined at the time of withdrawal. Cumulative effects are expected to be limited to periods of low flow (i.e. cumulative effects are unlikely during peak flow periods). See **Table 5-15.**

Cumulative effects may occur during periods where water users are simultaneously withdrawing water either upstream or downstream on the same streams as the Project withdrawals. This could include the following:

- domestic water withdrawal for communities of old crow and eagle plains, homesteads, camps, and eagle river hotel;
- road construction and maintenance;
- gravel quarry activity (e.g. water withdrawal for gravel washing, or in-stream alterations of flow);
- pumping authorizations for industrial uses including drilling, winter road construction and maintenance, camp use, and construction use;
- oil and gas exploration water use (e.g. drilling, road and pad construction water use, camp water use); and,
- mineral exploration (e.g. drilling, road and pad construction water use, camp water use.

Table 5-15. Characterization of Cumulative Effects on Water Resources

Criterion		Rating	Rationale
Magnitude		Negligible	The magnitude of cumulative change in water quantity is predicted to be negligible as water withdrawal locations are well-dispersed through the CESA and the distance between withdrawal locations will ameliorate much of the potential cumulative effect. In addition, withdrawals for the Project are limited to 10% of instantaneous flows, and trigger monitoring will be utilized to reduce or stop withdrawals at such a time the water reduction reaches the threshold.
Likelihood		Probable	Other water withdrawals outside of the Project will operate independently and is dependent on factors that are not certain.
Geographic Extent		Beyond regional	Any cumulative effect will extend beyond the RSA, as most other projects and activities that may contribute to cumulative effects are outside this area.
Duration, Frequency & Timing	Duration	Short-term	The cumulative effect of changes to water flow will only occur during the duration of multiple concurrent water withdrawal activities and is not expected to extend beyond the duration of pumping (e.g. days or weeks)
	Frequency	Periodic	The effect will be limited to periods of concurrent water withdrawals for multiple sources which is likely to be periodic, and result in a cumulative effect during periods of low flow.
	Timing	Year-Round	The effect is expected to occur primarily during the period of planned water withdrawal (winter) but may occur during other periods of concurrent water use year-round.

Criterion	Rating	Rationale
Reversibility	Reversible	Changes to water quantity are expected to be reversible with reductions or cessation of water withdrawals.

6 FISH AND FISH HABITAT

Fish were selected as a key Valued Environmental and Socio-Economic Component (VESEC) for the Project because of their cultural, ecological, and economic value, including fishing. Prior to the baseline report (**Appendix 6-A Fish and Fish Habitat Studies**), limited information was available on fish and fish habitat within the Regional Study Area (RSA).

The baseline report described that the RSA encompasses 1,467 mapped streams[9], most of which are smaller headwater streams: 1,142 first-order, 239 second-order, 68 third-order, 16 fourth-order, and 2 fifth-order streams. Few ponds and lakes occur in the RSA and none are greater than 5 hectares (ha) in size.

During the winter (March 2020), no fish were observed in the RSA (**Appendix 6-A**). Smaller streams (first, second, and third-order) fully freeze or dewater, whereas larger streams (fourth and fifth-order) have residual pools with no flow and associated low dissolved oxygen.

Most fish are suspected to migrate out of the study area to larger rivers for overwintering. During the summer, Arctic grayling (*Thymallus arcticus*), round whitefish (*Prosopium cylindraceum*), burbot (*Lota lota*), slimy sculpin (*Cottus cognatus*), and longnose sucker (*Catostomus catostomus*) were captured in the RSA (**Appendix 6-A**); no salmon (*Oncorhynchus* spp.) were captured.

No aquatic Species at Risk nor critical habitat have been identified or mapped in the RSA (Fisheries and Oceans Canada 2023a).

6.1 ASSESSMENT INDICATORS AND ASSESSMENT PARAMETERS

The Project has the potential to interact with fish and fish habitat, and the assessment indicators of potential adverse effects are changes in fish mortality and fish habitat. The assessment approach for fish mortality is a qualitative discussion of the changes in fish mortality risk. The assessment approach for fish habitat is a qualitative discussion of the changes in fish habitat quality, and quantity.

6.2 PROJECT INTERACTIONS AND POTENTIAL EFFECTS

The potential for the Project to interact with and adversely affect fish and fish habitat was assessed by systematically reviewing each of the components listed in the Project description (**Table 6-1**). The Project includes several components that have the potential to interact with and adversely affect fish and fish habitat. Each of these components received scores (0 = no interaction; 1 = minor interaction; 2 = substantial interaction) based on the expected magnitude of a potential adverse effect, in the absence of mitigation measures being applied. Only component-effect interactions with a score of 2 are considered in residual adverse effects characterization, whereas lower scores are associated with adverse effects that are small (immeasurable) or negligible.

[9] These numbers refer to mapped streams or drainages. Note many of the smaller 'streams' may not meet the definition of a stream (i.e., could be seepages, wet areas, or wetlands).

6.2.1 Interactions

Ten of the 12 Project components may interact with fish and fish habitat causing potential adverse effects by changes in fish mortality risk and fish habitat quality or quantity. The direct and indirect pathways for potential adverse effects because of the Project components are described in the following sections. See **Table 6.1**.

Table 6-1. Expected Interactions Between Fish and Fish Habitat and the Eagle Plains Exploration Project and Resulting Potential Effects

Project Component / Activity	Fish Mortality Risk	Fish Habitat Quality	Fish Habitat Quantity
Engagement	0	0	0
Seismic Exploration	2	2	2
Drilling Exploration	2	2	2
Extended Flow Testing (EFT)	2	2	0
Well Maintenance (Workovers)	0	0	0
Winter Access Roads	2	2	2
Mix Bury Cover (MBC)	2	2	0
Central Processing Facility (CPF)	2	2	0
Airstrip	2	2	0
Water Withdrawal	2	2	2
Transportation	0	0	0
Camp	2	2	0
Reclamation and Closure	2	2	0

Notes:
0 = no interaction
1 = minor interaction with fish and fish habitat is possible, but small immeasurable effect (e.g., possible slight behavioural response). Designates a summary of effects addressed in the effects assessment as a discussion. This rating does not lead into residual effects characterization.
2 = substantial interaction with fish and fish habitat, designates a more detailed assessment of potential effects. Carry forward into residual effects characterization.

6.2.2 Fish Mortality Risk

Fish mortality risk may directly increase because of seismic exploration (detonation of charges). The source points of the seismic lines will be buried at typically 6 metre (m) depth with charges of up to 1 kilogram (kg) that may produce shock waves and increase noise in fish habitat; shot point noise is 1 second in duration and is not a continuous noise. A shock wave greater than 30 kiloPascals (kPa) can cause damage to fish swim bladders, internal organs, eggs, and larvae, translating to fish mortality or a range of sub-lethal effects. Fisheries and Oceans Canada (DFO) recommends that noise should not exceed 206 decibels (dB) re: 1 microPascal (µPa) (equivalent to 30 kPa) at the edge of fish exclusion zones (Wright and Hopky 1998).

Fish mortality risk may directly and indirectly increase because of water withdrawal. Withdrawing water too quickly can strand fish in dewatered areas that may result in direct fish mortality. Improperly sized intake screens may impinge or entrain fish translating to direct fish mortality or body damage. Water withdrawal during the winter may indirectly increase icing via increasing the frequency of icing and in-stream ice formation. Water withdrawal can cause fish mortality when the degree of icing is high (e.g., fish mortality due to scouring, dewatering, smothering, or freezing of the channel bed).

Fish mortality risk may directly and indirectly increase because of the Project by the mechanism of the introduction of contaminants. The charges used for seismic exploration or chemicals/fluids associated with drilling exploration (e.g., hydrochloric acid), extended flow testing (e.g., crude oil), mixed bury cover (e.g., drill cuttings), central processing facility (e.g., chemical storage), airstrip (e.g., aviation fuel), and camp (e.g., wastewater) may introduce contaminants into the water directly or indirectly via runoff if the component is adjacent to streams. Similarly, inadvertent leaks or accidental spills from mobile equipment (e.g., winter access roads) may introduce contaminants into water directly or indirectly via runoff if the mobile equipment is adjacent to streams. Any uncured concrete used for drilling exploration and reclamation and closure is particularly harmful to fish because of its alkaline properties (high pH) and elevated heavy metal concentrations. Uncured concrete may introduce contaminants into water directly or indirectly via runoff if the concrete works are adjacent to streams. Contaminant introductions can induce toxic effects, including fish mortality and sub-lethal effects such as tumours, organ damage, physical deformities, growth, and reproductive disorders.

6.2.3 Fish Habitat Quality

Fish habitat quality may indirectly decrease because of water withdrawal. Water withdrawal during the winter may indirectly increase icing via increasing the frequency of icing and in-stream ice formation. Water withdrawal can cause decreases in fish habitat quality when the degree of icing is low, e.g., fish displacement or dispersal from lower quality habitat.

Fish habitat quality may directly and indirectly decrease because of the Project via an increase in sediment concentrations, as Total Suspended Solids (TSS). TSS may directly increase during seismic exploration (detonation of charges) because of the re-suspension of fine sediment from the stream bed. TSS may increase during drilling exploration and reclamation and closure if uncured concrete enters water directly or indirectly via runoff. TSS may indirectly increase via erosion related to winter access roads near streams. TSS increases can cause decreases in fish habitat quality because fish and benthic invertebrates have reduced ability to seek and capture prey, fish can get coated gill structures (causing irritation and asphyxiation), and these species are exposed to lower dissolved oxygen concentrations. The settlement of TSS can also cause the mortality of benthic invertebrates by smothering.

Fish habitat quality may indirectly decrease because of seismic exploration (lines), drill exploration (wells), and winter road access. The removal of riparian vegetation for these activities may indirectly increase water temperature via the loss of shade, and indirectly decrease nutrient input via the loss of leaf litter and insect drop. Water temperature increases and nutrient input decreases can cause decreases in fish habitat quality. That is, water temperature increases may translate to accelerated development and thermal stress for fish. Nutrient input decreases may translate to decreased food production for fish.

6.2.4 Fish Habitat Quantity

Fish habitat quantity may directly decrease because of winter access roads, drilling exploration, and seismic exploration activities. Stream crossings for winter access roads may place structures into aquatic areas, translating to decreases in the aquatic habitat available to fish, as well as the potential to decrease fish passage to favourable habitat. Wells for drilling exploration and lines for seismic exploration may remove vegetation such as trees, translating to decreases in the riparian habitat available to fish.

Fish habitat quantity may directly decrease because of water withdrawal. Water withdrawal decreases the wetted area and water depth, translating to decreases in the aquatic habitat available to fish. The decreases in water depth may impede fish movement, translating to decreases in fish passage to favourable habitat. Water withdrawal can isolate habitat because of the dewatering of shallow sections or other features passable at higher flows, also translating to decreased fish passage to favorable habitat.

6.3 MITIGATION MEASURES

The Project has a comprehensive set of measures designed to mitigate potential effects on fish and fish habitat. Standard mitigation measures to minimize residual effects of the Project on fish and fish habitat are described in this section and presented in **Table 6-2**.

To avoid causing the death of fish and/or the harmful alteration, disruption or destruction (HADD) of fish habitat, DFO recommends that projects should be conducted in accordance with DFO's "*Measures to Protect Fish and Fish Habitat*:" (Fisheries and Oceans Canada 2023b) , which includes mitigation measures related to avoiding aquatic areas, avoiding riparian areas, least risk timing, maintaining riparian vegetation, erosion and sediment control, and deleterious substance control. Mitigation measures are also provided within the DFO Codes of Practice (Fisheries and Oceans Canada 2020, 2023c). To use a Code of Practice, a notification form will be submitted to the regional DFO office 10 working days before starting work. Mitigation measures are also provided in DFO *Guidelines for Use of Explosives In or Near Canadian Fisheries Waters* (Wright and Hopky 1998).

The Project has maximized the avoidance of aquatic areas. First, the number of temporary stream crossings for winter access roads will be minimized on first and second-order streams (19 crossings across all 10 scenarios) and on third-order and higher order streams (average 4.2 crossings, range 4 to 5 crossings, across the 10 scenarios). This mitigation translates to crossings on 1% of first and second-order streams (19 out of 1,706) and up to 6% of third-order and higher order streams (5 out of 86). These crossings will also be temporary, as they will be removed in the spring, limiting temporal interactions with aquatic areas. Second, siting of exploration drilling, extended flow testing (EFT), reclamation and closure, mix, bury, cover (MBC), airstrip, camp, and Central Processing Facility (CPF) will minimize the proximity near streams by avoiding the riparian reserve zone (40 or 50 m width) and will minimize overlap with the riparian management zone (40, 60, or 70 m width) behind the reserve zone. Thus, introduction of contaminants because of accidental releases and spills near streams has been minimized for these components.

The Project has maximized the avoidance of riparian areas by minimizing activities in the riparian zone as described in the simulations. Specifically, existing roads will be used, and wells and spur roads will be limited in riparian reserve zones (40 or 50 m width) closest to the streams (average 4.89 ha, range 4.85 to 4.99 ha, across the 10 scenarios), as well as in riparian management zones (40, 60, or 70 m width) behind

the reserve zone (average 6.53 ha, range 6.15 to 47.26 ha). This translates to average riparian reserve zone impacts of 0.03% in the RSA (out of 19,043.14 ha) and average riparian management zone impacts of 0.03% in the RSA (out of 21,095.33 ha). Some seismic lines will be in the riparian areas (reserve 499.35 ha and management 577.33 ha across the 10 scenarios) with a potential footprint amounting to 2.7% of the riparian zone within the RSA. Furthermore, temporary stream crossings for the winter roads will select for shallow banks and riparian areas with less vegetation to minimize vegetation removal. To minimize bank erosion, roots will not be removed. Seismic exploration (lines) where crossings are not present will use hand cutting within a 10-m-width zone to minimize vegetation removal, and roots will not be removed to minimize bank erosion.

Project component interactions with fish and fish habitat will be limited during the winter because fish are generally not in the RSA based on the findings of the baseline studies (**Appendix 6-A**). Project component interactions with fish and fish habitat will also be limited spatially and temporally because the Project will also likely focus on one of the multiple work areas every few years (1 to 3) within the RSA.

Most of the Project components occur during the winter (November to April) under frozen conditions, except for seismic exploration activities during the summer. Drilling exploration, and reclamation and closure activities contain concrete works. Project components in or near water, including the use of mobile equipment, have the potential for accidental releases of contaminants. Thus, the Project will follow standard mitigation for concrete works, as well as spill prevention and response (**Table 6-2**). Winter access road construction, water withdrawal, and activities in the riparian zone will follow the DFO *Code of Practice:* Ice bridges and snow fills (Fisheries and Oceans Canada 2023c; **Table 6-2**).

Seismic exploration may occur during the summer (June to October). The DFO least risk timing windows for the Porcupine and Peel drainages are July 15 to May 1 (Arctic grayling) and May 1 to September 1 (whitefish species). Given the small overlap in the two windows (July 15 to September 1) and that grayling dominated the catches (85%) during baseline studies, the grayling window takes precedence. This approach is supported by the data that display only two round whitefish were captured within the RSA, as well as no fry nor juveniles were captured. Arctic grayling fry, indicative of spawning, were captured in second to fifth-order streams during baseline studies. As such, detonation of seismic charges should not be completed near (i.e., riparian zone) second to fifth-order streams from May 1 to July 15. Detonation will also follow the DFO *Guidelines for Use of Explosives in or Near Canadian Fisheries Waters* (Wright and Hopky 1998) (**Table 6-2**).

Detonation charges will be 1 kg or less for the seismic lines. For example, the minimum setback distances for a 1 kg charge are 11 m considering the 30 kiloPascal (kPa) threshold for shock waves and 16 m considering the incubation period of May 1 to July 15 for second to fifth-order streams (Wright and Hopky 1998). However, the Project will provide a setback distance of 45 m, providing a conservative mitigation approach for seismic exploration.

Detonation charges will typically be buried at 6 m depth in a hole. A charge at 6 m depth is below the permafrost (typically greater than 2 m) and above the deep groundwater (greater than 100 to 200 m), such that potential contaminants in the charges should not be mobilized by water. However, charges that are buried in the suprapermafrost (typically less than 2 m, surface groundwater) may mobilize potential contaminants by water to the streams; thus, for mitigation, all charges are to be buried below the suprapermafrost, which may be up to 3 to 4 m locally in some areas (e.g., due to recent wildfire). Although

suprapermafrost (surface groundwater) will drain into the hole with the charge, any water that overtops the hole after detonation will refreeze because of the permafrost conditions including during the summer so potential contaminants should not be mobilized by water. Surface runoff will also be limited during the summer to mobilize potential contaminants because of (1) few heavy rainfall events to fully saturate the surface and, (2) the mossy organic layer at the surface mimics a water absorbing sponge. Therefore, the mobilization of potential contaminants in the charges by water to the streams will be minimized.

Table 6-2. Mitigation Measures Relevant to Fish and Fish Habitat and the Project

Mitigation Measure	Potential Effect Addressed by Mitigation
Winter road construction, which will have the greatest water requirements, will primarily occur in November, December, and, to a lesser degree, January to reduce water withdrawal needs during the lowest flow periods (February and March)	Fish Habitat Quality, Fish Habitat Quantity
All wastewater and sewage will be collected in tanks approved by the Canadian Standards Association , treated on-site, then released as clean water back into the environment	Fish Mortality Risk; Fish Habitat Quality
Minimize Project activities in and near the aquatic areas	Fish Mortality Risk; Fish Habitat Quality; Fish Habitat Quantity
With the exception of seismic lines, Project features will be located outside the RMA (and particularly the RMZ), to the extent practicable. Overlap with a small extent of the RMZ is permissible where operations cannot completely avoid them.	Fish Mortality Risk; Fish Habitat Quality
For seismic activities, with the exception of mechanical watercourse crossings, restrict all mechanical equipment 55 m away from the bank edge	Fish Mortality Risk; Fish Habitat Quality
For mechanical seismic watercourse crossings, employ the following crossing site selection criteria: • areas with natural clearings, where available; • shallow banks • good bank stability; • areas with shallow water (e.g., not on bends in the river); • areas with 90 degrees access to the river; and • creek location that freezes to bottom.	Fish Mortality Risk; Fish Habitat Quality
Minimize the number of stream crossings, especially on 3rd order and higher streams.	Fish Mortality Risk; Fish Habitat Quality
Where stream crossings occur, align the road to minimize the extent of the RMA that is affected	Fish Mortality Risk; Fish Habitat Quality
Concentrate Project activities in the winter	Fish Mortality Risk; Fish Habitat Quality
If concrete works are required near streams, avoid concrete works when precipitation events are anticipated within 72 hours and the work cannot be contained	Fish Mortality Risk; Fish Habitat Quality

Mitigation Measure	Potential Effect Addressed by Mitigation
Avoid concrete spillage	Fish Mortality Risk; Fish Habitat Quality
Isolate concrete and concrete wash from the aquatic and riparian environment	Fish Mortality Risk; Fish Habitat Quality
Construct all concrete forms so that they are properly sealed (e.g., properly sealed and locked chutes, hose, and hose connections)	Fish Mortality Risk; Fish Habitat Quality
Maintain a carbon dioxide (CO_2) tank with a regulator, hose and gas diffuser on site to neutralize pH levels if a concrete spill to water occurs	Fish Mortality Risk; Fish Habitat Quality
Isolate and hold any water that contacts uncured or partly cured concrete until the pH is less than 9.0 (BC freshwater quality guideline for pH is 6.5 to 9.0) (British Columbia Ministry of Environment and Climate Change Strategy 2023)	Fish Mortality Risk; Fish Habitat Quality
All mobile equipment brought on site will be clean, free of leaks, excess oil and grease, and in good working order	Fish Mortality Risk
All mobile equipment will be checked every morning for leaks and good working order	Fish Mortality Risk
Hydraulic machinery, if required, will use environmentally sensitive hydraulic fluids that are non-toxic to aquatic life and are readily or inherently biodegradable	Fish Mortality Risk
Refuelling, fuel stockpiling, and maintenance of mobile equipment will be limited to designated areas on level, impermeable surface areas at least 30 m away from water	Fish Mortality Risk
All refuelling will occur using funnels, pads, and drip pans in place	Fish Mortality Risk
Fuels, lubricants, and chemicals will be stored appropriately on site, with proper controls to prevent the release of deleterious substances, in a designated area at least 30 m away from water	Fish Mortality Risk
Properly sized oil drip pans will be placed under all equipment and vehicles left on site	Fish Mortality Risk
Develop and implement a Spill Response Plan	Fish Mortality Risk
The Spill Response Plan will (1) include a list of spill response equipment that will be present on site; (2) assign implementation and monitoring roles; and, (3) require site personnel to have reviewed the plan, understand their roles and responsibilities, and are properly trained and equipped to conduct spill response activities	Fish Mortality Risk
Identify high-risk locations where spills are probable and maintain spill kits, capable of handling the largest potential spill through the duration of the Project, at these locations	Fish Mortality Risk
Locate Personal Protective Equipment (PPE) at the top of the spill kit to ensure easy access for the spill responder	Fish Mortality Risk
Keep spill kits closed with a safety seal affixed to indicate if the kit has been used or tampered with	Fish Mortality Risk
Respond immediately to all spills in accordance with plan	Fish Mortality Risk
If any accidental spills occur, they shall be immediately contained, cleaned up and reported (if reportable amount or type).	Fish Mortality Risk

Mitigation Measure	Potential Effect Addressed by Mitigation
Winter access road construction will follow the DFO *Code of Practice: Ice bridges and snow fills* (Fisheries and Oceans Canada 2023c)	Fish Mortality Risk; Fish Habitat Quality
Locate a temporary crossing site where the watercourse is straight, banks are stable and where approaches have low slopes	Fish Habitat Quality
Operate vehicles and machinery in a manner that minimizes disturbance to the watercourse bed and banks	Fish Habitat Quality
Do not leave logs or woody debris within the watercourse or on the banks where they can wash back into the watercourse	Fish Habitat Quality
If logs are used for watercourse crossing construction, ensure that the logs are clean and securely bound together, and are removed before the spring freshet	Fish Habitat Quality
Place a v-notch in centre of the ice bridge when crossing season is over (and it is safe to do so) to prevent blocking fish passage, channel erosion, and flooding	Fish Habitat Quality
Use only clean materials (i.e., water, ice, snow) to construct ice bridge	Fish Mortality Risk; Fish Habitat Quality
Remove compacted snow from the snow fills prior to the spring freshet	Fish Habitat Quality
Water withdrawal will follow the DFO *Code of Practice: Ice bridges and snow fills* (Fisheries and Oceans Canada 2023c)	Fish Mortality Risk; Fish Habitat Quantity; Fish Habitat Quality
Screen intake pipes when pumping (DFO Code for fish protection screens) (Fisheries and Oceans Canada 2020)	Fish Mortality Risk
Water withdraw will not exceed 10% of the actual (instantaneous) flow	Fish Mortality Risk; Fish Habitat Quantity; Fish Habitat Quality
Activities in the riparian zone will follow the DFO *Code of Practice: Ice bridges and snow fills* (Fisheries and Oceans Canada 2023c)	Fish Mortality Risk; Fish Habitat Quality; Fish Habitat Quantity
Use existing trails, roads, access points or cut lines wherever possible	Fish Habitat Quantity; Fish Habitat Quality
Use methods to reduce soil compaction (e.g., swamp mats, pads)	Fish Habitat Quality
Limit vegetation removal, pruning, and grubbing to the area required for accessing the site of the works, undertakings, and activities	Fish Habitat Quantity; Fish Habitat Quality
Construct roads, access points, and approaches perpendicular to the watercourse if a new access point is required to reach the watercourse	Fish Habitat Quality
Construct approaches using clean compacted snow and ice to a sufficient depth to protect the banks of the watercourse	Fish Mortality Risk; Fish Habitat Quality
Restore the banks and riparian vegetation affected by the works, undertakings, and activities to their natural state	Fish Habitat Quantity; Fish Habitat Quality
Do not use ammonium nitrate-fuel oil mixtures	Fish Mortality Risk
Charges will be buried at a depth below the suprapermafrost (surface groundwater) layer	Fish Mortality Risk
Do not place charge shot holes in obvious drainage wells	Fish Mortality Risk
After loading a charge in a hole, the hole is to be back-filled or collapsed to confine the force of the detonation	Fish Mortality Risk

Mitigation Measure	Potential Effect Addressed by Mitigation
All "shock-tubes" and detonation wires are to be recovered and removed after each detonation	Fish Habitat Quality
Follow the setback distance of 45 m. For cases where this is not possible, the minimum setback distance is 11 m from any stream for 1 kg explosive to avoid risk of producing an instantaneous pressure change (i.e., overpressure) greater than 30 kPa (**Table 6-3**)	Fish Mortality Risk
Seismic exploration should not be completed near second to fifth-order streams May 1 to July 15. Charge detonation will also follow the DFO *Guidelines for Use of Explosives in or Near Canadian Fisheries Waters* (Wright and Hopky 1998).	Fish Mortality Risk; Fish Habitat Quality
If seismic exploration must occur May 1 to July 15 near second to fifth-order streams, follow the setback distance of 45 m. For cases where this is not possible, the minimum setback distance is 16 m from the stream for 1 kg of explosive to a peak particle velocity greater than 13 mm/s in a spawning bed (**Table 6-4**).	Fish Mortality Risk

6.4 EFFECTS CHARACTERIZATION

6.4.1 Approach

Characterizing the residual adverse effects on fish and fish habitat considers the Project's potential effects and the mitigation measures used to minimize those potential effects. The spatial boundary of effects characterization was the RSA. Residual effects on fish and fish habitat have each been characterized in terms of magnitude, likelihood, geographic extent, duration, timing, frequency, and reversibility (**Table 6-5**). Determining residual effects on fish and fish habitat considered the context of the highest development (conforms to Regional Land Use Plans) and the confidence in accurately quantifying and predicting those residual effects. The significance of all residual effects (after mitigation measures are applied) is assessed collectively to determine the overall residual effect of the Project on fish and fish habitat (see **Section 6.5 Significance**).

Table 6-5. Definitions of Effects Criteria Classifications for the Assessment of Fish and Fish Habitat in the Eagle Plains Exploration Project

Criterion		Rating	Definition
Magnitude		Negligible	No measurable change from existing conditions. **This corresponds to a <1% change in an assessment indicator.**
		Low	The residual effect will be a slight, but measurable change from existing conditions. **This corresponds to a 1–10% change in an assessment indicator.**
		Moderate	The residual effect will be a measurable change from existing conditions but will not affect the sustainability of fish and fish habitat. **This corresponds to a 11–35% change in an assessment indicator.**
		High	The residual effect will be a substantial, measurable change from existing conditions that may affect the sustainability of fish and fish habitat. **This corresponds to a >35% change in an assessment indicator.**
Likelihood		Unlikely	A residual effect is not expected, but a residual effect is not impossible.
		Possible	A residual effect may occur but is not likely.
		Probable	A residual effect is likely to occur, but it is not certain.
		Certain	A residual effect will occur.
Geographic Extent		Maximum disturbance footprint	The residual effect is confined to the maximum disturbance footprint.
		Local	The residual effect is confined to the Local Study Area.
		Regional	The residual effect is confined to the Regional Study Area.
		Beyond regional	The residual effect extends beyond the Regional Study Area.
	Duration	Short-term	The residual effect duration is less than a year (e.g., days, months)

Criterion		Rating	Definition
Duration, Frequency and Timing		Medium-term	The residual effect duration is more than a year and up to the life of the Project (e.g., years).
		Long-term	The residual effect duration is beyond the life of the Project (e.g., decades).
		Permanent	The residual effect is predicted to be permanent and thus unlikely to recover to existing conditions.
	Frequency	Occasional	The residual effect may occur rarely (e.g., once or a few times over the life of the Project).
		Periodic	The residual effect may occur consistently at regular intervals or associated with temporal events (e.g., during spring freshet, low flows, growing season).
		Continuous	The residual effect may occur all the time.
	Timing	Year-round	The residual effect may occur year-round.
		Seasonal	The residual effect may be confined to a portion of the year.
Reversibility		Reversible	The residual effect is predicted to be reversible within a clearly defined period.
		Irreversible	The residual effect is predicted to influence the assessment indicator indefinitely.

6.4.2 Fish Mortality Risk

Table 6-6 presents the characterization of residual adverse effects for fish mortality risk. Provided the implementation of all mitigation measures in the previous section, a residual adverse effect (as an increase in fish mortality risk) is not anticipated for the Project. Any residual effect (e.g., accidental spill) may be in the RSA geographic extent and of unlikely likelihood. Any residual effect may be medium-term duration (life of the Project), occasional frequency, and seasonal (summer). Although the loss of an individual to mortality is irreversible, it is anticipated to have a negligible magnitude at the population level.

Table 6-6. Characterization of Residual Effects on Fish Mortality Risk

Criterion	Rating	Rationale
Magnitude	Negligible	Mitigation measures are expected to minimize changes in fish mortality risk. For example, 1% of first and second-order streams will have temporary crossings and up to 6% of third and higher order streams will be crossed. Riparian reserve zone and management zone impacts of 0.03% outside of seismic lines and 2.7% for seismic lines. If a residual effect were to occur, fish mortality may be negligible at the population level (i.e., a very small number of fish would be affected rather than population effects).
Likelihood	Unlikely	Mitigation measures are expected to minimize the likelihood of changes in fish mortality risk.

Criterion		Rating	Rationale
Geographic Extent		Regional	Any change in fish mortality risk will be limited to the RSA.
Duration, Frequency and Timing	Duration	Medium-term	If a residual effect were to occur, fish mortality may be for the Project (medium-term).
	Frequency	Occasional	If a residual effect were to occur, fish mortality may be limited to occasional events.
	Timing	Seasonal	If a residual effect were to occur, fish mortality will be limited to the summer, when fish are in the RSA. Interactions with fish will be limited during the winter, when most Project components occur, because fish are generally not in the RSA.
Reversibility		Irreversible	If a residual effect were to occur, fish mortality may be irreversible at the individual level.

6.4.2.1.1 Context and Confidence

The confidence of no residual adverse effect anticipated is high for fish mortality risk within the context of Regional Land Use Planning (**Table 6-7**). For example, the mitigation is effective for confined explosive setbacks.

Table 6-7. Context and Confidence of Residual Effects on Fish Mortality Risk

Criterion	Rating	Rationale
Context	Conforms to Regional Land Use Plans	The RSA is within Land Management Unit IV zones of the North Yukon and Peel Regional Land Use Plans (LUPs), which are areas zoned for the highest level of development. The Project activities are consistent with the integrated resource management objectives of the LUPs.
Confidence	High	High confidence (low uncertainty) in the ability to characterize Project interactions for fish mortality risk, i.e., few knowledge gaps, and the mitigation is effective.

6.4.3 Fish Habitat Quality

Table 6-8 presents the characterization of residual adverse effects for fish habitat quality. Provided the implementation of all mitigation measures in the previous section, a residual adverse effect (as a decrease in fish habitat quality) is not anticipated for the Project. Any residual effect (e.g., loss of a few riparian trees) may be in the RSA geographic extent and of unlikely likelihood. Any residual effect may be long-term duration (time for riparian trees to return), occasional frequency, reversible, and negligible magnitude.

Table 6-8. Characterization of Residual Effects on Fish Habitat Quality

Criterion		Rating	Rationale
Magnitude		Negligible	Mitigation measures are expected to minimize changes in fish habitat quality. For example, 1% of first and second-order streams will have temporary crossings and up to 6% of third and higher order streams will be crossed. Riparian reserve zone and management zone impacts of 0.03% outside of seismic lines and 2.7% for seismic lines. If a residual effect were to occur, decreases in fish habitat quality may be negligible (very small portion of streams would be affected).
Likelihood		Unlikely	Mitigation measures are expected to minimize the likelihood of changes in fish habitat quality.
Geographic Extent		Regional	Any change in fish habitat quality will be limited to the RSA.
Duration, Frequency and Timing	Duration	Long-term	If a residual effect were to occur, decreases in fish habitat quality may be long-term (recover to baseline), as it will take time for banks to re-stabilize and riparian trees to return, i.e., sediment, temperature, and nutrients.
	Frequency	Occasional	If a residual effect were to occur, decreases in fish habitat quality may be limited to occasion events.
	Timing	Seasonal	If a residual effect were to occur, decreases in fish habitat quality may be limited to the summer, when fish are in the RSA. Fish habitat quality interactions will be limited during the winter, when most Project components occur, because fish are generally not in the RSA.
Reversibility		Reversible	If a residual effect were to occur, decreases in fish habitat quality are reversible in the long term.

6.4.3.1.1 Context and Confidence

The confidence of no residual adverse effect anticipated is high for fish habitat quality within the context of Regional Land Use Planning for the Project (**Table 6-9**). For example, the mitigation is effective for temporary stream crossings, sediment and erosion control, concrete works, and spill management and response.

Table 6-9. Context and Confidence of Residual Effects on Fish Habitat Quality

Criterion	Rating	Rationale
Context	Conforms to Regional Land Use Plans	The RSA is within Land Management Unit IV zones of the North Yukon and Peel Regional Land Use Plans, which are areas zoned for the highest level of development. The Project activities are consistent with the integrated resource management objectives of the LUPs.
Confidence	High	High confidence (low uncertainty) in the ability to characterize Project interactions for fish habitat quality, i.e., few knowledge gaps, and the mitigation is effective.

6.4.4 Fish Habitat Quantity

Table 6-10 presents the characterization of residual adverse effects for fish habitat quantity. Provided the implementation of all mitigation measures in the previous section, a residual adverse effect (as a decrease in fish habitat quantity) is not anticipated for the Project. Any residual effect (e.g., accidental water withdrawal exceedance) may be in the RSA geographic extent and of unlikely likelihood. Any residual effect may be short-term duration (time for water withdrawal activity), occasional frequency, reversible, and negligible magnitude.

Table 6-10. Characterization of Residual Effects on Fish Habitat Quantity

Criterion		Rating	Rationale
Magnitude		Negligible	Mitigation measures are expected to minimize changes in fish habitat quantity. For example, 1% of first and second-order streams will have temporary crossings and up to 6% of third and higher order streams will be crossed. Riparian reserve zone and management zone impacts of 0.03% outside of seismic lines and 2.7% for seismic lines. If a residual effect were to occur, decreases in fish quantity may be negligible (very small portion of streams would be affected).
Likelihood		Unlikely	Mitigation measures are expected to minimize the likelihood of changes in fish habitat quantity.
Geographic Extent		Regional	Any change in fish habitat quantity will be limited to the RSA.
Duration, Frequency and Timing	Duration	Short-term	If a residual effect were to occur, decreases in fish habitat quantity may be short-term (time for water withdrawal activity).
	Frequency	Occasional	If a residual effect were to occur, decreases in fish habitat quantity may be limited to occasional events.
	Timing	Seasonal	If a residual effect were to occur, decreases in fish habitat quantity may be limited to the summer, when fish are in the RSA. Interactions to fish habitat quantity will be limited during the winter, when most Project components occur, because fish are generally not in the RSA.
Reversibility		Reversible	If a residual effect were to occur, decreases in fish habitat quantity are reversible in the short term.

6.4.4.1.1 Context and Confidence

The confidence of no residual adverse effect anticipated is high for fish habitat quantity within the context of Regional Land Use Planning (**Table 6-11**). For example, the mitigation is effective for avoiding aquatic and riparian areas, and water withdrawal, e.g., do not exceed 10% of the actual (instantaneous) flow.

Table 6-11. Context and Confidence of Residual Effects on Fish Habitat Quantity

Criterion	Rating	Rationale
Context	Conforms to Regional Land Use Plans	The RSA is within Land Management Unit IV zones of the North Yukon and Peel Regional Land Use Plans, which are areas zoned for the highest level of development. The Project activities are consistent with the integrated resource management objectives of the LUPs.
Confidence	High	High confidence (low uncertainty) in the ability to characterize Project interactions for fish habitat quantity, i.e., few knowledge gaps, and the mitigation is effective.

6.5 SIGNIFICANCE

Significance was evaluated as part of the residual effects characterization for fish and fish habitat. **Table 6-12** provides the definition of significant versus not significant that were used.

Table 6-12. Determination of Significance for Residual Effects on Fish and Fish Habitat

Characterization	Definition
Not Significant	Management standards or mitigation measures are designed to minimize the likelihood and severity of residual effects.
Significant	Management standards or mitigation measures are not adequate to minimize the likelihood and severity of residual effects.

The Project is not anticipated to substantially affect fish and fish habitat. The Project was designed to limit interactions with fish and fish habitat by minimizing stream crossings and riparian area footprints to the extent practical, as well as most of the activities have been scheduled during the winter when fish are generally not in the RSA. Standard mitigation measures have been applied to the Project, and these measures are known to be effective at minimizing residual adverse effects. The confidence is high for no residual effects for fish mortality risk, fish habitat quality, and fish habitat quantity. Any residual effect for fish and fish habitat (e.g., loss of a small number of trees within riparian areas), is anticipated to be of negligible magnitude for fish mortality risk, fish habitat quality, and fish habitat quantity. Therefore, residual effects of the Project on fish and fish habitat from the three potential sources collectively are anticipated to be **negligible**.

6.6 CUMULATIVE EFFECTS ASSESSMENT

Given that residual effects of the Project on fish and fish habitat were predicted to be **negligible**, an assessment of cumulative effects on Fish and Fish Habitat was not conducted.

7 VEGETATION

Ecological communities play an important role in the maintenance of biodiversity, carbon sequestration, nutrient cycling, productivity and wildlife habitat. Ecological communities provide habitat for culturally important and harvestable plants and at-risk components of regional, territorial and federal biodiversity.

Field surveys completed by EDI Environmental Dynamics Inc. (EDI) have documented 125 different plant species, including 6 tree species, 29 shrub species, 48 forb species, 7 ferns and allies, 12 graminoid species, 11 lichen species, 10 moss species, and 2 liverwort species throughout the Regional Study Area (RSA) (**Appendix 7-A Ecological and Landscape Classification Mapping**). None of the vegetation species observed were listed by the Committee on the Status of Endangered Wildlife in Canada (COSEWIC), under the federal *Species at Risk Act*, or on the Yukon track and watch species list.

In addition to these individual vegetation species, thirty-one distinct ecosystem units have been mapped within the RSA. Most of the RSA is mapped in a shrub structural stage with only 1 percent (%) of the RSA mapped in an old forest structural stage.

The RSA is dominated by moist and mesic black and white spruce forests, with Labrador tea (*Rhododendron groenlandicum*), alder (*Alnus* spp.) and birch (*Betula* spp.) shrub cover. The least common ecological units are found on dry sites or have been influenced by disturbances and are dominated by birch and willow (*Salix* spp.). Bogs were the most common wetland ecosystem unit mapped across the RSA, with some fens and marshes also mapped. No swamps were identified during the field program nor mapped within the RSA (**Appendix 7-A**).

The ecosystem units identified in the Ecological and Landscape Classification mapping were assessed for cultural value, rarity, conservation status, habitat values, and sensitivity to disturbance. Four groups of ecosystem units were identified for inclusion in the constraints mapping (dry sites, riparian spruce sites, tamarack sites, and unique wetland sites). In addition, all sites mapped as old forest were included in the constraints maps.

7.1 ASSESSMENT INDICATORS AND ASSESSMENT PARAMETERS

Methods used in the vegetation assessment align with established guidance for an environmental assessment process in the Yukon and Canada. The vegetation assessment methods follow the general methods noted in **Section 3**, with additional Valued Environmental and Socio-Economic Component (VESEC) specific methods provided in this section as needed.

The assessment of the potential effects of the Eagle Plains Exploration Project (the Project) on the Vegetation VESEC focuses on two indicators: tamarack-producing ecosystem units and ecosystem units of conservation concern. The assessment of these indicators consists of a quantitative assessment of the change in area for each of the two indicators. These indicators were identified based on Indigenous input and/or potential sensitivity, rarity, or value to wildlife.

The assessment focuses on changes to tamarack-producing ecosystem units and to changes to ecosystem units of conservation concern. Ecosystem units of conservation concern were identified as the following: dry ecosystem units, riparian spruce sites and unique wetland sites. The assessment of units of conservation concern included changes in old growth forest.

The change (alteration or loss) of selected indicators were quantified by calculating the area of each indicator that could potentially be affected by Project activities. Calculated disturbance areas were then compared to baseline areas to determine the area of alteration or loss. Project effects focused on the calculated maximum Project Footprint from the ten well site scenarios (see **Section 3.1.3**), but also discuss the minimum, and average Project footprints from those scenarios.

7.2 PROJECT INTERACTIONS AND POTENTIAL EFFECTS

7.2.1 Interactions Table

Certain Project works may interact with vegetation and result in potential effects. Specifically seismic exploration, drilling exploration, and construction of the winter access, Central Processing Facility (CPF), airstrip and camp are expected to interact with the vegetation VESEC (**Table 7-1**).

Table 7-1. Expected Interactions Between the Vegetation VESEC and Project Activities, By Type of Potential Effect

Project Component / Activity	Loss or Alteration of Wet Shrub Tamarack Ecosystem	Loss or Alteration of Ecosytem Units of Conservation Concern
Engagement	0	0
Seismic Exploration	2	2
Drilling Exploration	2	2
Extended Flow Testing (EFT)	1	1
Well Maintenance (Workovers)	2	2
Access Roads	2	2
Mix Bury Cover (MBC) Construction and Operation	2	2
Central Processing Facility (CPF)	1	1
Airstrip	2	2
Water Withdrawal	1	1
Transportation	2	2
Camp	2	2
Reclamation and Closure	1	1

Notes:
0 = no interaction
1 = minor interaction with vegetation is possible, but small immeasurable effect (e.g., possible slight behavioural response, no vegetation effects, no measurable effect on water quality). Designates a summary of effects addressed in the effects assessment as a discussion. This rating does not lead to the characterization of residual effects.
2 = substantial interaction with vegetation, designates a more detailed assessment of potential effects. Carry forward into residual effects characterization.

7.2.2 Loss or Alteration of Wet Shrub Tamarack Ecosystem

Tamarack sites are described as areas with greater than 5% tamarack cover, low presence of *Cladonia* species (caribou forage species) and a high presence of S*phagnum* or glow moss. Scrub birch and Labrador tea are present in the shrub layer. These sites are often present in thin strips between bog and riparian areas. The soil moisture regime ranges from hygric to subhydric and the soil nutrient regime ranges from poor to medium. Distinct to prominent mottles can be observed, seepage is present, and the permafrost layer is near the surface. A layer of ice is typically present within or above the frozen soil or frozen organic layer. The RSA contains approximately 177 ha of the Wet Shrub Tamarack ecosystem unit (**Table 7-2**) which is the only identified tamarack ecosystem unit in the RSA.

Table 7-2. Availability of Tamarack Ecosystems and Ecosystems of Conservation Concern in the Eagle Plains RSA

Ecosystem Group	Name	Baseline	
		Total RSA Area (hectares [ha])	% of RSA
Tamarack Sites	Wet Shrub – Tamarack	177.3	0.1
Dry Ecosystem Sites	Dry Spruce-Lichen (Conifer)	1,826.5	0.8
Dry Ecosystem Sites	Dry Aspen-Lichen (Deciduous)	280.8	0.1
Dry Ecosystem Sites	Dry Spruce-Birch-Lichen (Mixedwood)	2,103.6	0.9
Dry Ecosystem Sites	Dry Aspen (Deciduous)	80.1	<0.1
Riparian Spruce Sites	Riparian White Spruce – Prickly Rose	192.1	0.1
Riparian Spruce Sites	Riparian Spruce – Birch - Willow	674.4	0.3
Unique Wetland Sites	Fen	42.5	<0.1
Unique Wetland Sites	Marsh	59.5	<0.1
Old forest	Structural stage 8	2,302.7	1.0

The development of Project components necessitates alteration and, in some small cases, complete removal of vegetation within Wet Shrub Tamarack ecosystems. The vast majority of Project Footprint features (winter roads, well pads, seismic lines) will require removal of trees and tall shrubs, but low shrubs and groundcover will remain. In these areas, Wet Shrub Tamarack ecosystems will be altered but not completely removed. Select Project Footprint features will require complete removal of all vegetation.

7.2.3 Loss or Alteration of Ecosystem Units of Conservation Concern

All four ecosystem units of conservation concern (dry ecosystem units, riparian spruce sites, unique wetland sites, and old growth forest) are present within the RSA (**Appendix 7-A**). The following sections summarize their availability within the RSA and potential effects of the Project on each.

7.2.3.1 Dry Ecosystem Units

This dry ecosystem unit grouping is composed of four forested ecosystem units: Dry Spruce – Lichen, Dry Aspen – Lichen, Dry Spruce – Birch – Lichen and Dry Aspen. The RSA is comprised of approximately 1.8% of this dry ecosystem unit grouping. The most common of this grouping is the Dry Spruce – Birch – Lichen

(Mixedwood) (2,104 ha) and the least common is the Dry Aspen (80 ha) (**Table 7-2**). These areas typically provide caribou forage and are not commonly found across the RSA, as they are typically associated with steep south-facing slopes.

The Dry Spruce – Lichen ecosystem unit is a spruce (*Picea* species) dominated conifer stand with an understory composed of shrubs such as scrub/shrub birch *(Betula glandulosa*), prickly rose (*Rosa acicularis*), lowbush cranberry (*Vaccinium vitis-idaea*), alpine blueberry (*Vaccinium uliginosum*) and crowberry (*Empetrum nigrum*) and a small component of Alaska paper birch (*Betula neoalaskana*) in the canopy. This ecosystem unit typically has less than 2% forb cover, has no graminoid cover, and less than 5% moss cover, but greater than 50% lichen cover (caribou forage).

The Dry Aspen – Lichen ecosystem unit is an aspen dominated deciduous stand on south-facing slopes with an understory composed of lowbush cranberry, crowberry, and bearberry. This ecosystem unit may have greater than 5% forb cover, less than 1% graminoid cover and less than 5% moss cover. The lichen cover (caribou forage) is high.

The Dry Spruce – Birch – Lichen ecosystem unit is a mixedwood dominated stand supporting spruce and Alaska paper birch, with an understory of prickly rose, lowbush cranberry, bearberry (*Arctostaphylos uva-ursi*), less than 2% forb cover and less than 10% moss cover. This ecosystem unit has greater than 30% lichen cover (caribou forage).

The Dry Aspen ecosystem unit is a pure aspen dominated deciduous stand composed of very dry to dry soil nutrient regimes on moderate to steep slopes. This unit is very low in *Cladonia* species (caribou forage species) cover (less than 5%). These areas typically have poor soil nutrient regimes.

The development of Project components necessitates alteration and, in some small cases, complete removal of vegetation within dry ecosystem units that overlap Project Footprints. The vast majority of Project Footprint features (winter roads, well pads, seismic lines) that overlap these ecosystems will require removal of trees and tall shrubs, but low shrubs and groundcover will remain. In these areas, dry ecosystem units will be altered but not completely removed. Some of the low shrub and ground vegetation may be compacted during development of these sites, which may slow down the growth and spread of plants but is not expected to affect the survival of the plants. Select Project Footprint features will require complete removal of all vegetation where it overlaps with these ecosystems.

7.2.3.2 Riparian Spruce Sites

The RSA supports approximately 0.4% of the Riparian Spruce unit grouping. This grouping is comprised of the Riparian White Spruce – Prickly Rose ecosystem unit and the Riparian Spruce – Birch – Willow ecosystem unit.

Riparian White Spruce – Prickly Rose units are dominated by white spruce (*Picea glauca*) with a mixture of shrub species, but rose is present in the understory. These units are usually a thin strip of trees along streams and rivers. Typically, these units are considered to be mesic but some can be described as being subhygric. Most of these units have a medium to rich soil nutrient regime. Approximately 192 ha of this ecosystem unit was mapped within the RSA (**Table 7-2**).

Riparian Spruce – Birch – Willow areas are dominated by white and black spruce (*Picea mariana*); some Alaska paper birch may also be present, with a mixture of shrub species such as scrub birch and willow (*Salix* species) in the understory. This ecosystem unit is typically moister (subhygric to hygric) than the

White Spruce – Prickly Rose units and usually form a wider strip of trees along streams and rivers. Faint to distinct mottles can be observed in the soil, slight seepage can be present, and permafrost may also be present but at variable depths. Signs of flooding may be observed. Within the RSA, approximately 674 ha of the Riparian Spruce – Birch – Willow ecosystem unit was mapped (**Table 7-2**).

The development of Project components necessitates alteration and, in some small cases, complete removal of vegetation within riparian spruce sites that overlap Project Footprints. The vast majority of Project Footprint features (winter roads, well pads, seismic lines) that overlap these ecosystems will require removal of trees and tall shrubs, but low shrubs and groundcover will remain. In these areas, riparian spruce ecosystem units will be altered but not completely removed. Some of the low shrub and ground vegetation may be compacted during development of these sites, which may slow down the growth and spread of plants but is not expected to affect the survival of the plants. Select Project Footprint features will require complete removal of all vegetation where it overlaps with these ecosystems.

7.2.3.3 Unique Wetland Sites

The RSA supports approximately 2,828 ha of sites classified as wetlands, including bogs, fens and marshes. Fens and marshes are considered unique wetland sites within the RSA, as only 103 ha of these wetland types were mapped within the RSA.

Fens are a shrubby or graminoid peatland ecosystem unit where groundwater inflow maintains relatively high mineral content within the rooting zone. Graminoid fens have greater than 20% Sphagnum or moss cover. This ecosystem has a hydric moisture regime and a nutrient regime that can range from poor to rich. These sites generally have a thick fibric organic layer and there is the presence of permafrost. Seepage is often present. The RSA contains approximately 43 ha of fen wetland habitat (**Table 7-2**).

A marsh is a shallowly flooded mineral wetland ecosystem dominated by emergent vegetation. The area is usually dominated by graminoids and has less than 10% *Sphagnum* or moss cover. Seepage, permafrost and gleying are often observed in the soils within these areas. Approximately 60 ha of marsh habitat was mapped within the RSA (**Table 7-2**).

The development of Project components necessitates alteration and, in some small cases, complete removal of vegetation within unique wetland sites that overlap Project Footprints. The vast majority of Project Footprint features (winter roads, well pads, seismic lines) that overlap these ecosystems will require removal of trees and tall shrubs, but low shrubs and groundcover will remain. In these areas, unique wetland sites may be altered but not completely removed. Some of the low shrub and ground vegetation may be compacted during development of these sites, which may slow down the growth and spread of plants but is not expected to affect the survival of the plants. Select Project Footprint features may require complete removal of all vegetation where it overlaps with these ecosystems.

7.2.3.4 Old Forest

Old forest structural stage is defined as forested stands having complex structure with abundant large-sized trees, snags and coarse woody debris and comprised entirely of shade-tolerant overstory species with well-established canopy gaps (Yukon Government Department of Environment 2017). About 1% of the RSA is in an old forest structural stage. The majority of the old forest was mapped within the moist and mesic ecological units. Old forest was only mapped within two Dry Ecosystem units (Dry Spruce-Lichen (101 ha)

and Dry Spruce-Birch-Lichen Mixedwood (64.6 ha)) and one Riparian Spruce ecosystem unit (243 ha) (**Table 7-2**).

The development of Project components necessitates alteration and, in some small cases, complete removal of vegetation within old forest sites that overlap Project Footprints. The vast majority of Project Footprint features (winter roads, well pads, seismic lines) that overlap these ecosystems will require removal of trees and tall shrubs, but low shrubs and groundcover will remain. In these areas, the loss of trees will result in a change in structural stage and loss of old forest characteristics; the ecosystems may remain but will now be an early seral (shrub-dominated) ecosystem. Some of the low shrub and ground vegetation may be compacted during development of these sites, which may slow down the growth and spread of plants but is not expected to affect the survival of the plants. Select Project Footprint features may require complete removal of all vegetation where it overlaps with these ecosystems.

7.3 MITIGATION MEASURES

The Project will implement mitigation measures that are specific, measurable, verifiable and achievable in nature to avoid and minimize the effects on Vegetation. Several mitigation measures proposed within the constraints mapping phase of the Project have been incorporated into the Project's design to reduce the magnitude, duration, and extent of the Project's effects. **Table 7-3** identifies mitigation measures that will be implemented to minimize the effects of the Project on Vegetation

Table 7-3. Mitigation Measures

Mitigation Measure	Potential Adverse Effect
Avoid or minimize the overlap of Project components within tamarack-producing units and ecosystem units of conservation concern by applying the constraints map during the Project design phase.	• Loss or alteration of Wet Shrub Tamarack ecosystem • Loss or alteration of ecosystem units of conservation concern
Minimize the spatial extent of new components by using existing infrastructure (e.g. roads, winter trails, seismic lines) wherever feasible.	• Loss or alteration of Wet Shrub Tamarack ecosystem • Loss or alteration of ecosystem units of conservation concern
Delineate the Project Footprint boundaries and restrict equipment use to within the defined areas.	• Loss or alteration of Wet Shrub Tamarack ecosystem • Loss or alteration of ecosystem units of conservation concern
Minimize vegetation and soil compaction within tamarack-producing units, fens and marshes with the use of mats or other anti-compaction approved methods and materials.	• Loss or alteration of Wet Shrub Tamarack ecosystem • Loss or alteration of ecosystem units of conservation concern
Develop a plan to prevent deleterious substances from entering a water body	• Loss or alteration of Wet Shrub Tamarack ecosystem • Loss or alteration of ecosystem units of conservation concern
Maintain all machinery on site in a clean condition and free of fluid leaks	• Loss or alteration of Wet Shrub Tamarack ecosystem

Mitigation Measure	Potential Adverse Effect
	• Loss or alteration of ecosystem units of conservation concern
Wash, refuel and service machinery in upland areas in such a way as to prevent any deleterious substances from entering a water body	• Loss or alteration of Wet Shrub Tamarack ecosystem • Loss or alteration of ecosystem units of conservation concern
Store fuel and other materials for the machinery in such a way as to prevent any deleterious substances from entering a water body	• Loss or alteration of Wet Shrub Tamarack ecosystem • Loss or alteration of ecosystem units of conservation concern
Establish a spill response plan with the following key mitigation measures: • report all spills as soon as possible when a deleterious substance enters a water body; • install containment measures around the spill; and, • collect and dispose of contaminated water or soil substrates using an emergency spill kit and other necessary spill response measures. Disposal will be at approved disposal facilities.	• Loss or alteration of Wet Shrub Tamarack ecosystem • Loss or alteration of ecosystem units of conservation concern
Allow for the regeneration of natural vegetation following the cessation of exploration in a work area	• Loss or alteration of Wet Shrub Tamarack ecosystem • Loss or alteration of ecosystem units of conservation concern
Limit grubbing activities (i.e., removal of groundcover) to the drill hole location and the MBC sumps	• Loss or alteration of Wet Shrub Tamarack ecosystem • Loss or alteration of ecosystem units of conservation concern
Limit clearing of vegetation to the height of 0.1 m high wherever practicable	• Loss or alteration of Wet Shrub Tamarack ecosystem • Loss or alteration of ecosystem units of conservation concern
Develop and implement an erosion and sediment control plan to prevent the introduction of sediment into any water body during all phases of the Project, undertakings and activities	• Loss or alteration of Wet Shrub Tamarack ecosystem • Loss or alteration of ecosystem units of conservation concern
Install erosion and sediment control measures, where appropriate, before beginning works, undertakings and activities	• Loss or alteration of Wet Shrub Tamarack ecosystem • Loss or alteration of ecosystem units of conservation concern
Maintain and inspect erosion and sediment control measures and structures regularly during all phases of the works, undertakings and activities	• Loss or alteration of Wet Shrub Tamarack ecosystem • Loss or alteration of ecosystem units of conservation concern
Keep the erosion and sediment control measures in place until all disturbed ground has been stabilized, then remove all erosion and sediment control materials (unless biodegradable)	• Loss or alteration of Wet Shrub Tamarack ecosystem • Loss or alteration of ecosystem units of conservation concern

Mitigation Measure	Potential Adverse Effect
Keep organic layers intact (i.e., limit grubbing and vegetation removal) wherever possible	• Loss or alteration of Wet Shrub Tamarack ecosystem • Loss or alteration of ecosystem units of conservation concern
Operate machinery on land in stable, dry areas	• Loss or alteration of Wet Shrub Tamarack ecosystem • Loss or alteration of ecosystem units of conservation concern
Monitor waterbodies regularly for signs of sediment entry during all phases of the works, undertakings and activities and take corrective action	• Loss or alteration of Wet Shrub Tamarack ecosystem • Loss or alteration of ecosystem units of conservation concern
Use biodegradable erosion and sediment control materials whenever possible	• Loss or alteration of Wet Shrub Tamarack ecosystem • Loss or alteration of ecosystem units of conservation concern
Minimize source line widths to 2.75 m and receiver line widths to 1.75 m and the total length of lines as much as possible (i.e., use as wide a spacing distance between lines as possible)	• Loss or alteration of Wet Shrub Tamarack ecosystem • Loss or alteration of ecosystem units of conservation concern
Wash and inspect all equipment prior to arrival on site to minimize the potential for invasive plant introduction and spread	• Loss or alteration of Wet Shrub Tamarack ecosystem • Loss or alteration of ecosystem units of conservation concern

7.4 EFFECTS CHARACTERIZATION

7.4.1 Approach

The assessment of alteration of ecosystems of conversation concern considers the alteration or loss of these units across the range of the 10 Project footprint scenarios. The direct alteration is quantified by calculating the area predicted to be affected within the RSA and compared to baseline values. The data are presented as minimum, maximum and average values for the potential Project footprint areas that could be altered within the RSA by various Project components and subcomponents.

Based on the scenario modelling, a maximum Project footprint of 7,188 ha could potentially be affected by Project related activities (**Table 7-4**). Of this maximum Project footprint, approximately 151 ha overlaps with areas already devoid of vegetation (i.e., the existing camp and the Dempster Highway). The majority (88%) of the Project footprint is the areas to be affected by seismic line clearing, where low shrub and ground cover vegetation will be retained. A further 7.8% of the Project Footprint will be winter roads and trails, where low shrub and ground cover vegetation will also be retained to the maximum extent possible, within the limitations of safe construction of winter roads and trails (e.g., cutting large stumps down to ground level may sometimes be required).

An average of approximately 7,015 ha of new "disturbances" is expected to affect vegetation and ecosystems, with the majority constituting an alteration; only a small fraction of the area is predicted to be lost completely (i.e., all vegetation completely removed and grubbed).

Table 7-4. The Minimum, Maximum and Average Areas of Effect Footprint Features on the Vegetation and Ecosystems Within the Project Footprint

Footprint Feature	Minimum Footprint Area (ha)	Maximum Footprint Area (ha)	Average Footprint Area (ha)
Seismic component	6,335.2	6,337.7	6,336.3
Winter Roads and Trails	561.8	563.1	562.6
Well features	71.5	117.7	97.3
Proposed camp	12.0	12.0	12.0
Airstrip	6.8	6.8	6.8
Existing camp	8.8	8.8	8.8
Dempster Highway	142	142	142
Total Area (ha)	7,138.1	7,188.1	7,165.8

Based on the scenario modeling, the greatest range between the potential minimum Project Footprint and maximum Project footprint is associated with well features (**Table 7-4**), which include both well sites and associated well access (i.e., spur access to individual well sites). Project-related ecosystem alterations associated with well features have the potential to range from 71 ha to 118 ha (**Table 7-4**). Most of the other proposed Project Footprint features have range differences that are less than 2 ha or have a fixed Footprint.

Most of the Project footprint will be associated with seismic components (**Table 7-4**), which encompass three-dimensional (3D) combination, 3D receiver, and 3D source lines, as well as seismic access. Within the seismic Project Footprints, trees and tall shrubs will be cut down and some ground vegetation could be compacted/crushed. An average area of approximately 6,336 ha is expected to be altered in association with seismic features activities. It is assumed that these activities will cause minimal soil disturbance and the cutting of trees and tall shrubs within all seismic areas across the RSA will not be completed within the same winter but rather will be progressively conducted across the RSA over the life of the Project. Seismic components will be spread throughout the RSA and not be concentrated in one area or within one ecosystem unit. Once the proposed tree and shrub removal on seismic components is completed, natural regeneration of the line is expected occur.

Characterizing the residual adverse effects on vegetation considers the Project's potential effects and the mitigation measures used to minimize those potential effects. The spatial boundary of effects characterization was the RSA. Residual effects on vegetation have each been characterized in terms of magnitude, likelihood, geographic extent, duration, timing, frequency, and reversibility (**Table 7-5**). Determining residual effects on vegetation considered the context of the Regional Land Use Plans and the confidence in accurately quantifying and predicting those residual effects. The significance of all residual

effects (after mitigation measures are applied) is assessed collectively to determine the overall residual effect of the Project on vegetation.

Table 7-5. Definitions of Effects Criteria Classifications for the Assessment of Vegetation in the Eagle Plains Exploration Project

Criterion		Rating	Definition
Magnitude		Negligible	No measurable change from existing conditions. This corresponds to a <1% change in an assessment indicator.
		Low	The residual effect will be a slight, but measurable change from existing conditions. This corresponds to a 1–5% change in an assessment indicator.
		Moderate	The residual effect will be a measurable change from existing conditions but will not affect the sustainability of wildlife and wildlife habitat. This corresponds to a 5–15% change in an assessment indicator.
		High	The residual effect will be a substantial, measurable change from existing conditions that may affect the sustainability of wildlfie and wildlife habitat. This corresponds to a >15% change in an assessment indicator.
Likelihood		Unlikely	A residual effect is not expected, but a residual effect is not impossible.
		Possible	A residual effect may occur but is not likely.
		Probable	A residual effect is likely to occur, but it is not certain.
		Certain	A residual effect will occur.
Geographic Extent		Maximum disturbance footprint	The residual effect is confined to the maximum disturbance footprint.
		Local	The residual effect is confined to the Local Study Area.
		Regional	The residual effect is confined to the RSA.
		Beyond regional	The residual effect extends beyond the RSA.
Duration, Frequency and Timing	Duration	Short-term	The residual effect duration is less than a year (e.g., days, months)
		Medium-term	The residual effect duration is more than a year and up to the life of the Project (e.g., years).
		Long-term	The residual effect duration is beyond the life of the Project (e.g., decades).
		Permanent	The residual effect is predicted to be permanent and thus unlikely to recover to existing conditions.
	Frequency	Occasional	The residual effect may occur rarely (e.g., once or a few times over the life of the Project).
		Periodic	The residual effect may occur consistently at regular intervals or associated with temporal events (e.g., during spring freshet, low flows, growing season).
		Continuous	The residual effect may occur all the time.

Criterion		Rating	Definition
	Timing	Year-round	The residual effect may occur year-round.
		Seasonal	The residual effect may be confined to a portion of the year.
Reversibility		Reversible	The residual effect is predicted to be reversible within a clearly defined period.
		Irreversible	The residual effect is predicted to influence the assessment indicator indefinitely.

7.4.2 Vegetation Data Limitations

The following technical limitations apply to the vegetation baseline data used to support predicting Project residual effects:

- Vegetation baseline ecosystem mapping accuracy and resolution were limited by the availability of imagery quality, and challenges with attributing fire-disturbed polygons.
- No primary traditional knowledge information was collected for the vegetation assessment. Sources of traditional knowledge were limited to publicly available secondary sources cited in the baseline reports and assessment where appropriate.

7.4.3 Residual Loss or Alteration of Wet Shrub Tamarack Ecosystem

The Project may alter Wet Shrub Tamarack ecosystem units within the RSA across all 10 Project Footprint scenarios. It is estimated that up to 5.5 ha will be disturbed by Project-related activities (**Table 7-6**), which constitutes approximately 3% of the total available Wet Shrub - Tamarack ecosystem unit across the RSA. This low magnitude residual effect is predicted to last for the long-term, but be reversible, once trees and tall shrubs regenerate following cessation of Project activities (**Table 7-7**).

Table 7-6. Area of Wet Shrub Tamarack Ecosystem Predicted to be Lost or Altered Due to the Project, Based on an Assessment of the 10 Project Footprint Scenarios

Ecosystem Group	Name	Footprint Disturbance Scenarios			
		Min Area (ha)	Max Area (ha)	Avg Area (ha)	Avg % Change from Baseline
Tamarack Sites	Wet Shrub – Tamarack	5.5	5.5	5.5	3.1

Table 7-7. Residual Effects Characterization for Loss or Alteration of Wet Shrub Tamarack Ecosystems

Criterion		Rating	Rationale
Magnitude		Low	The change in the relative availability of Wet Shrub Tamarack ecosystems from baseline is 3%
Likelihood		Certain	Mitigation measures are expected to minimize but not eliminate the potential alteration or loss of Wet Shrub Tamarack ecosystems.
Geographic Extent		Maximum disturbance footprint	Direct habitat loss is predicted to be limited to the Project footprint.
Duration, Frequency & Timing	Duration	Long-term	Tamarack and other trees can take many years to regenerate, and thus it's predicted that regeneration of Wet Shrub Tamarack ecosystems could extend beyond the completion of exploration and associated reclamation, but is likely to recover to baseline over time.
	Frequency	Periodic	Vegetation clearing will be required for most Project related activities but will occur in phases.
	Timing	Year-round	Once vegetations is altered or lost, the residual effect from this alteration or loss will remain year-round until regeneration is complete.
Reversibility		Reversible	The regeneration of vegetation is expected to reverse the alteration/loss in Wet Shrub Tamarack ecosystems.

In a study completed by EDI (**Appendix 7-B Linear Feature Study**) on linear feature regeneration within the RSA, a key finding was that normal succession was the dominant trajectory observed for all linear features except the Dempster Highway. The majority of 3D seismic lines followed a normal succession trajectory. It was theorized that it was due to low impact methods used in 3D line creation that minimized ground and vegetation disturbance, creating conditions conducive to a normal successional trajectory (Yukon Energy Mines and Resources 2006, Golder Associates 2016). Thus, it's predicted that recovery of most affected Wet Shrub Tamarack ecosystems (especially those along Project Low Impact Seismic [LIS] lines) could be much faster than on historical two-dimensional (2D) lines and other clearing disturbances.

Tree growth rates in the Eagle Plains area are not known; similar species that occur in Eagle Plains were observed to grow 5–10 centimetres (cm) per year on 3D lines in the boreal forest in northeast BC (Golder Associates 2016). If similar growth rates occur in Eagle Plains, regeneration on the 3D lines could be 2 metres (m) over the next 5 to 20 years.

7.4.3.1.1 Context and Confidence

The Project is within a Zone IV Integrated Management Area (IMA) in both the North Yukon and Peel Watershed Planning Regions. In these areas with diminished ecological and cultural values in a moderately sensitive biophysical setting, Zone IV IMAs allows for the highest level of development. Cumulative effect indicators are used in both plans to determine if the current management and development is meeting the set goals and objectives. Two cumulative effects indicators included in the Plans are direct surface disturbance and linear density, with guidelines setting cautionary (0.75 kilometres [km] / square kilometres [km²]) and critical (1.0 km/km²) indicator levels in both plans.

Chance Oil and Gas Ltd. (Chance) commissioned a study to determine the extent and characteristics of liner features in the RSA (**Appendix 7-B**). The study supports assessing the Project's potential effects of linear features and refinement of mitigation measures for linear features to minimize the potential for adverse effects. After accounting for natural features and regeneration, the adjusted linear feature density for the RSA was below the cautionary indicator level, at 0.52 km/km², in both RLUPs.

With minimal ground disturbance, the maintenance of moss, herb, and low shrub layers is expected to support natural vegetation regeneration. Longer regenerating times are often caused or exacerbated by human use after the initial disturbance; however, extensive (non-Project) human use does not appear to be a factor in the RSA, as no sign of human use was observed outside of the Dempster Highway corridor during the EDI linear feature study (EDI Environmental Dynamics Inc 2023).

The uncertainty of the final Project Footprint results in a moderate confidence rating of the characterization of the predicted residual effects on Wet Shrub Tamarack ecosystems (**Table 7-8**).

Table 7-8. Rating and Rationale for Context and Confidence

Criterion	Rating	Rationale
Context	Highest Development	The RSA is within a Zone IV IMA — Highest Level of Development is allowed.
Confidence	Moderate	Mitigation measures are predicted to be effective at minimizing a change in vegetation, however, the uncertainty of the Project Footprint results in a Moderate Confidence of the characterization of the residual effect prediction to specific ecological units.

7.4.4 Residual Loss or Alteration of Ecosystems of Conservation Concern

Depending on the ecosystem of conservation concern, the Project may affect up to 3.7% of the available quantity of these ecosystems in the RSA across all 10 Project Footprint scenarios (**Table 7-9**). This low magnitude residual effect is predicted to last for the long-term, but be reversible, once trees and tall shrubs regenerate following cessation of Project activities (**Table 7-10**).

Table 7-9. Area of Wet Shrub Tamarack Ecosystem Predicted to be Lost or Altered Due to the Project, Based on an Assessment of the 10 Project Footprint Scenarios

Ecosystem Group	Name	Footprint Disturbance Scenarios			
		Min Area (ha)	Max Area (ha)	Avg Area (ha)	Avg % Change from Baseline
Dry Ecosystem Sites	Dry Spruce-Lichen (Conifer)	57.1	59.5	58.1	3.2
Dry Ecosystem Sites	Dry Aspen-Lichen (Deciduous)	8.9	8.9	8.9	3.2
Dry Ecosystem Sites	Dry Spruce-Birch-Lichen (Mixedwood)	65.4	67.6	65.9	3.1
Dry Ecosystem Sites	Dry Aspen (Deciduous)	2.8	2.9	2.9	3.6

Ecosystem Group	Name	Footprint Disturbance Scenarios			
		Min Area (ha)	Max Area (ha)	Avg Area (ha)	Avg % Change from Baseline
Riparian Spruce Sites	Riparian White Spruce – Prickly Rose	4.7	4.7	4.7	2.5
Riparian Spruce Sites	Riparian Spruce – Birch - Willow	16.9	16.9	16.9	2.5
Unique Wetland Sites	Fen	1.3	1.3	1.3	3.1
Unique Wetland Sites	Marsh	2.2	2.2	2.2	3.7
Old Forest	Structural stage 8	70.6	71.0	70.7	0.03

Table 7-10. Residual Effects Characterization for Loss or Alteration of Ecosystems of Conservation Concern

Criterion		Rating	Rationale
Magnitude		Low	The change in the relative availability of selected ecological units from baseline will be less than 5%
Likelihood		Certain	Mitigation measures are expected to minimize but not eliminate the potential alteration or loss of Wet Shrub Tamarack ecosystems.
Geographic Extent		Maximum disturbance footprint	Direct habitat loss is predicted to be limited to the Project footprint.
Duration, Frequency & Timing	Duration	Long-term	Old forest can take many years to regenerate post-clearing and regeneration of certain ecological communities could extend beyond the completion of exploration and associated reclamation, but is likely to recover to baseline over time.
	Frequency	Periodic	Vegetation clearing will be required for most Project related activities but will occur in phases.
	Timing	Year-round	Once vegetations is altered or lost, the residual effect from this alteration or loss will remain year-round until regeneration is complete.
Reversibility		Reversible	The regeneration of vegetation is expected to reverse the alteration/loss of ecosystems of conservation concern..

7.4.4.1.1 Context and Confidence

The Project is within a Zone IV IMA in both the North Yukon and Peel Watershed Planning Regions. In these areas with diminished ecological and cultural values in a moderately sensitive biophysical setting, Zone IV IMAs allows for the highest level of development. Cumulative effect indicators are used in both plans to determine if the current management and development is meeting the set goals and objectives. Two cumulative effects indicators included in the Plans are direct surface disturbance and linear density, with guidelines setting cautionary (0.75 km/km²) and critical (1.0 km/km²) indicator levels in both plans.

Chance commissioned a study to determine the extent and characteristics of liner features in the RSA (**Appendix 7-B**). The study supports assessing the Project's potential effects of linear features and refinement of mitigation measures for linear features to minimize the potential for adverse effects. After accounting for natural features and regeneration, the adjusted linear feature density for the RSA was below the cautionary indicator level, at 0.52 km/km², in both RLUPs.

With minimal ground disturbance, the maintenance of moss, herb, and low shrub layers is expected to support natural vegetation regeneration. Longer regenerating times are often caused or exacerbated by human use after the initial disturbance; however, extensive (non-Project) human use does not appear to be a factor in the RSA, as no sign of human use was observed outside of the Dempster Highway corridor during the EDI linear feature study (EDI Environmental Dynamics Inc 2023). The uncertainty of the final Project Footprint results in a moderate confidence rating of the characterization of the predicted residual effects on selected ecosystem units and old forests (**Table 7-11**).

Table 7-11. Rating and Rationale for Context and Confidence

Criterion	Rating	Rationale
Context	Highest Development	The RSA is within a Zone IV IMA — Highest Level of Development is allowed.
Confidence	Moderate	Mitigation measures are predicted to be effective at minimizing a change in vegetation, however, the uncertainty of the Project Footprint results in a Moderate Confidence of the characterization of the residual effect prediction to specific ecological units.

7.5 SIGNIFICANCE

7.5.1 Significance Criteria

The significance of potential effects is discussed at the Vegetation VESEC level and not for each indicator selected. The magnitude of total vegetation area effects is a key consideration for all the vegetation effects assessments and significance determinations —how much vegetation will be lost due to Project activities. No published thresholds exist to define a significant versus not significant effect on vegetation or ecosystems in the Yukon. The Project assessment used a qualitative definition of significance, based on available data and professional judgement (**Table 7-12**).

Table 7-12. Determination of Significance

Characterization	Definition
Not Significant	The residual effect is not expected to result in a change to ecosystems that could alter the viability or persistence of those ecosystems within the RSA.
Significant	The residual effect may result in a change to ecosystems that could alter the viability or persistence of those ecosystems within the RSA. (i.e., where it is not sustainable or is unavailable to contribute to biodiversity and ecosystem function).

With a low magnitude effect, less than 4% of any given assessed ecosystem predicted to be affected, the majority of the Project effects constituting alteration (through removal of trees and tall shrubs) rather than complete removal (clearing and grubbing of all vegetation), and the prediction that LIS Project Footprints

(the vast majority of the Project Footprint) will experience natural succession, the predicted residual effects of the Project on the vegetation VESEC are not expected to result in a change in ecosystem units within the RSA to the point where they are no longer regionally viable or persistent. Therefore, the residual effect is on vegetation is **not significant**.

7.6 CUMULATIVE EFFECTS ASSESSMENT

7.6.1 Approach

Project-related residual effects with the potential to interact cumulatively with the residual effects of reasonably foreseeable projects and activities identified within or extending into the Cumulative Effects Study Area (CESA) are:

- loss or alteration of Wet Shrub Tamarack ecosystems; and,
- loss or alteration of ecosystems of conservation concern.

The spatial boundaries of the cumulative effects assessment for the vegetation VESEC are delineated by the CESA as described in **Section 3.1.6.1.1**. Projects and activities outside the CESA, with potential effects within this area, were also included in this assessment. Temporal boundaries for assessing cumulative effects encompass past, present, and reasonably foreseeable future activities spanning the Project's lifespan.

7.6.2 Cumulative Loss or Alteration of Wet Shrub Tamarack Ecosystems

The assessment of the cumulative effect on Wet Shrub Tamarack ecosystems used the indicator of total surface disturbance (area [km²] and %) from anthropogenic footprints (e.g., mineral exploration, oil and gas) disturbed by the footprints for its characterization. Present conditions include a total area of 31.3 km² (0.3%) disturbed by past and present projects and activities within the CESA (**Table 7-13**). This is predicted to increase in the future by 0.2 km² (0.0%) following the inclusion of reasonably foreseeable projects and activities. The Project is expected to increase the amount of disturbed area over the existing conditions by a maximum of 47.9 km² (0.4%) within the CESA, resulting in a maximum disturbed area of 79.4 km² (0.7%) when combined with past, present, and reasonably foreseeable projects and activities.

Table 7-13. Cumulative Loss or Alteration of Wet Shrub Tamarack Ecosystems

Cumulative Effect Indicator	Condition	Cumulative Effects Study Area
Total Surface Disturbance (Footprints)	Present	31.3 km² (0.3%)
	Project	47.4–47.9 km² (0.4%)
	Future	0.2 km² (0.0%)
	Total Cumulative Effect	78.9–79.4 km² (0.7%)

A summary of the characterization of cumulative effect of the loss or alteration of Wet Shrub Tamarack ecosystems is provided in **Table 7-14**. It is predicted that <1% of the Wet Shrub Tamarack ecosystems present within the CESA may be affected by the Project and other projects and activities, and therefore the cumulative effect is negligible. The likelihood of the effect is probable due to the spatial uncertainty in the location of the Project and other projects and activities relative to Wet Shrub Tamarack ecosystems. The

geographic extent of this cumulative effect is expected to be beyond regional as the alteration of Wet Shrub Tamarack ecosystems is expected to occur throughout the CESA (beyond the RSA). The duration of the effect is expected to occur over the long-term due to the length of time required for Wet Shrub Tamarack ecosystems to regenerate following disturbance and reclamation. The frequency of the alteration of Wet Shrub Tamarack ecosystems is expected to be regular and, therefore, periodic. The timing of the effect is expected to occur year-round as the Project, in combination with other projects and activities, is anticipated to occur throughout the year. Regeneration of Wet Shrub Tamarack ecosystems is predicted to occur over time once many activities cease, and therefore is assessed as reversible.

Table 7-14. Characterization of Cumulative Loss or Alteration of Wet Shrub Tamarack Ecosystems

Criterion		Rating	Rationale
Magnitude		Negligible	The change in the relative availability of Wet Shrub Tamarack ecosystems across the CESA is < 1%.
Likelihood		Probable	Mitigation measures are expected to minimize but not eliminate the potential for the cumulative effect (i.e., anticipated vegetation clearing). Due to the uncertainty in the spatial location of the Project and other projects and activities, there is potential to avoid adverse effects on the vegetation indicators during detailed layout.
Geographic Extent		Regional	The effect is expected to occur throughout the CESA.
Duration, Frequency & Timing	Duration	Long-term	Wet Shrub Tamarack ecosystems can take many years to regenerate post-disturbance and could extend beyond the lifespan of the Project, but it is likely to recover to baseline over time.
	Frequency	Periodic	Vegetation alteration is expected to occur for the Project and other projects and activities as part of the assessment. The effect is anticipated to occur at regular intervals.
	Timing	Year-round	The effect may occur year-round due to the anticipated varying temporal nature of the Project and other projects and activities.
Reversibility		Reversible	The regeneration of Wet Shrub Tamarack ecosystems is expected to reverse any alteration that occurs.

7.6.2.1 Context and Confidence

The CESA is a Zone IV IMA in the North Yukon and Peel Watershed Planning Regions with which it overlaps. In these areas with diminished ecological and cultural values in a moderately sensitive biophysical setting, Zone IV IMAs allow for the highest level of development. The effects characterization is consistent with the objectives of existing Land Use Plans, and there is relatively high confidence that effects were accurately captured in the assessment.

The Level of Confidence in this prediction is High (**Table 7-15**). The effect of the alteration of Wet Shrub Tamarack ecosystems on vegetation is known, and the efficacy of mitigation measures has been supported through application on previous projects.

Table 7-15. Context and Confidence for Cumulative Effects of Loss or Alteration of Wet Shrub Tamarack Ecosystems

Criterion	Rating	Rationale
Context	Highest Development	The Project occurs within the IMA Zone IV Management Unit, designated as the highest level of disturbance.
Confidence	High	Mitigation measures are predicted to effectively minimize or eliminate the alteration of Wet Shrub Tamarack ecosystems. Therefore, there is high confidence in the characterization of cumulative effects and its persistence.

7.6.3 Cumulative Loss or Alteration of Ecosystems of Conservation Concern

The assessment of the cumulative loss or alteration of ecosystems of conservation concern used the indicator of total surface disturbance (area [km²] and %) from anthropogenic footprints (e.g., mineral exploration, oil and gas) disturbed by the footprints for its characterization. Present conditions include a total area of 82.5 km² (0.7%) disturbed by past and present projects and activities within the CESA (**Table 7-16**). This is predicted to increase in the future by 1.9 km² (0.0%) following the inclusion of reasonably foreseeable projects and activities. The Project is expected to increase the amount of disturbed area over the existing conditions by a maximum of 99.3 km² (0.9%) within the CESA, resulting in a maximum disturbed area of 183.8 km² (1.6%) when combined with past, present, and reasonably foreseeable projects and activities.

Table 7-16. Cumulative Loss or Alteration of Ecosystems of Conservation Concern

Cumulative Effect Indicator	Condition	Cumulative Effects Study Area
Total Surface Disturbance (Footprints)	Present	82.5 km² (0.7%)
	Project	98.2–99.3 km² (0.9%)
	Future	1.9 km² (0.0%)
	Total Cumulative Effect	182.6–183.8 km² (1.6%)

A summary of the characteristics of the cumulative effects on the loss of habitat is provided in **Table 7-17**. For all ecosystems of conservation concern, there is expected to be a change of <2% of their total availability across the CESA, resulting in a low magnitude effect. The likelihood of the cumulative effect is probable due to the spatial uncertainty in the location of the Project and other projects and activities relative to the assessed ecosystems. The cumulative effect is predicted to extend beyond the the RSA, with the effect occurring throughout the CESA. The duration of the effect is expected to occur over the long-term due to the length of time required for some of the assessed ecosystems to regenerate following disturbance. The frequency of the loss of habitat is expected to be periodic, with habitat loss occurring regularly. The timing of the effect is expected to occur year-round as projects and activities within the CESA are expected to result in the loss of habitat throughout the year. Regeneration of ecosystems of conservation concern is predicted to occur over time once many activities cease, and therefore is assessed as reversible.

Table 7-17. Characterization of Cumulative Loss or Alteration of Ecosystems of Conservation Concern

Criterion		Rating	Rationale
Magnitude		Low	The loss in the ecological communities across the CESA is < 2%.
Likelihood		Probable	Mitigation measures are expected to minimize but not eliminate the potential for a loss of habitat. Due to the uncertainty in the spatial location of the Project and other projects and activities, the effect is not certain, resulting in a probable rating.
Geographic Extent		Regional	Change in habitat quality is expected to occur across the CESA due to the location of the projects and activities.
Duration, Frequency & Timing	Duration	Long-term	Old forest and other ecological communities can take many years to regenerate following disturbance and extend beyond the Project's lifespan but are likely to recover to baseline over time.
	Frequency	Periodic	Vegetation clearing is expected to be required for the Project and other projects and activities. Clearing is expected to occur regularly.
	Timing	Year-round	Habitat loss is expected to occur year-round as a result of the projects and activities considered in this assessment.
Reversibility		Reversible	The regeneration of vegetation is expected to be reversible over time.

7.6.3.1 Context and Confidence

The CESA is a Zone IV IMA in the North Yukon and Peel Watershed Planning Regions with which it overlaps. In these areas with diminished ecological and cultural values in a moderately sensitive biophysical setting, Zone IV IMAs allow for the highest level of development. The effects characterization is consistent with the objectives of existing Land Use Plans, and there is relatively high confidence that effects were accurately captured in the assessment.

The Level of Confidence in this prediction is High (**Table 7-18**). The effect of loss or alteration of ecosystems of conservation concern is known, and the efficacy of mitigation measures has been supported through application on previous projects.

Table 7-18. Context and Confidence for Cumulative Effects of Loss or Alteration of Ecosystems of Conservation Concern

Criterion	Rating	Rationale
Context	Highest Development	The Project occurs within the IMA Zone IV Management Unit, designated as the highest level of disturbance.
Confidence	High	Mitigation measures are predicted to be effective at minimizing or eliminating habitat loss of ecosystems of conservation concern. Therefore, there is high confidence in the characterization of cumulative effects and its persistence.

8 WILDLIFE AND WILDLIFE HABITAT

This section assesses the Project's effects on wildlife, following the general methods approach and concepts described in Section 3 Methods. The assessment includes identifying Project interactions and effects, proposed mitigation to reduce and manage potential effects, characterization of residual Project and cumulative effects, and significance determination. Monitoring and follow-up programs to assess the effectiveness of mitigation measures and the accuracy of the predicitions in the assessment, and unforeseen Project-related effects are also described where appropriate.

The Wildlife and Wildlife Habitat Valued Environmental and Socio-Economic Components (VESECs) and the rationale for their selection are provided in Table 3-1 in Section 3. Wildlife and Wildlife Habitat VESECs include:

- American marten (marten);
- moose; and,
- birds.

The indicators and parameters used for determining a Project-related change on the Wildlife and Wildlife Habitat VESECs are presented in **Table 3-2** of **Section 3** and include habitat change and mortality risk for marten, moose, and birds.

8.1 WILDLIFE ASSESSMENT METHODS

Methods used in the wildlife assessment align with established guidance for an environmental assessment process in the Yukon and Canada. The wildlife assessment methods follow the general methods noted in **Section 3**. Characteristics that require more specification for the wildlife assessment are stated below.

The Regional Study Area (RSA, described in **Section 3, Table 3-3)** is also the Regional Assessment Area for marten, moose, and birds.

The indicators and assessment parameters for marten, moose, and birds are those identified in **Table 3-2** of **Section 3**: change in habitat and mortality risk. For each marten, moose, and birds, the assessment indicators and parameters and reasons for using them are described in detail in those species' sections.

The potential Project interactions and effects are described, and justification provided for each of the wildlife VESECs.

A table summary of mitigation measures specific to each of the wildlife VESECs is provided in each of the species sections. Similar mitigation measures are used for moose and marten for Project activities but different measures may be used for birds as Project activities occur primarily while birds are outside of the RSA (i.e., have migrated south out of the RSA).

8.1.1 Approach

Characterizing the residual adverse effects on wildlife and wildlife habitat considers the Project's potential effects and the mitigation measures used to minimize those potential effects. The spatial boundary of effects characterization was the RSA. Residual effects on wildlife and wildlife habitat have each been characterized

in terms of magnitude, likelihood, geographic extent, duration, timing, frequency, and reversibility (**Table 8-1**). Determining residual effects on wildlife and wildlife habitat considered the context of the highest development (conforms to Regional Land Use Plans) and the confidence in accurately quantifying and predicting those residual effects. The significance of all residual effects (after mitigation measures are applied) is assessed collectively to determine the overall residual effect of the Project on wildlife and wildlife habitat (**Sections 8.2.5, 8.3.5, 8.4.5**).

Table 8-1. Definitions of Effects Criteria Classifications for the Assessment of Wildlife and Wildlife Habitat in the Eagle Plains Exploration Project

Criterion		Rating	Definition
Magnitude		Negligible	No measurable change from existing conditions. This corresponds to a <1% change in an assessment indicator.
		Low	The residual effect will be a slight, but measurable change from existing conditions. This corresponds to a 1–10% change in an assessment indicator.
		Moderate	The residual effect will be a measurable change from existing conditions but will not affect the sustainability of wildlife and wildlife habitat. This corresponds to a 11–35% change in an assessment indicator.
		High	The residual effect will be a substantial, measurable change from existing conditions that may affect the sustainability of wildlfie and wildlife habitat. This corresponds to a >35% change in an assessment indicator.
Likelihood		Unlikely	A residual effect is not expected, but a residual effect is not impossible.
		Possible	A residual effect may occur but is not likely.
		Probable	A residual effect is likely to occur, but it is not certain.
		Certain	A residual effect will occur.
Geographic Extent		Maximum disturbance footprint	The residual effect is confined to the maximum disturbance footprint.
		Local	The residual effect is confined to the Local Study Area.
		Regional	The residual effect is confined to the Regional Study Area.
		Beyond regional	The residual effect extends beyond the Regional Study Area.
Duration, Frequency and Timing	Duration	Short-term	The residual effect duration is less than a year (e.g., days, months)
		Medium-term	The residual effect duration is more than a year and up to the life of the Project (e.g., years).
		Long-term	The residual effect duration is beyond the life of the Project (e.g., decades).
		Permanent	The residual effect is predicted to be permanent and thus unlikely to recover to existing conditions.
	Frequency	Occasional	The residual effect may occur rarely (e.g., once or a few times over the life of the Project).

Criterion		Rating	Definition
		Periodic	The residual effect may occur consistently at regular intervals or associated with temporal events (e.g., during spring freshet, low flows, growing season).
		Continuous	The residual effect may occur all the time.
	Timing	Year-round	The residual effect may occur year-round.
		Seasonal	The residual effect may be confined to a portion of the year.
Reversibility		Reversible	The residual effect is predicted to be reversible within a clearly defined period.
		Irreversible	The residual effect is predicted to influence the assessment indicator indefinitely.

A broader discussion and review of literature on the topic of the magnitude of habitat disturbance thresholds for wildlife in the context of environmental assessment was part of the review of the Jay Pipe Expansion Project in the Northwest Territories (Dominion Diamond 2014). That assessment provided a review of the scientific literature and showed that the literature does suggest a tolerance of a relatively high levels of disturbance by wildlife before a response to habitat effects. The citations below elaborate on some of those citations and provide relevant updated citations.

Swift and Hannon (2010) provide a meta-analysis of simulation and empirical small-scale (e.g., fungus and some insect habitat) and large-scale (e.g., birds and some mammals) studies on habitat pattern and habitat loss factors that lead to potential population-level effects. Their findings on habitat disturbance ranged broadly before a population-level effect was noted:

- **Simulation Studies** — **"**The threshold levels range across nearly the entire continuum of habitat proportion, from about 1 to 99% (though most fall between 10 and 50%)" [habitat remaining].
- **Empirical Small-Scale** — 20–40%, range from 20–100% habitat remaining.
- **Empirical Large-Scale** — 20%, 10–30% habitat remaining (e.g., effects noted at 70–90% habitat loss).

Regardless of the discussion above, Chance will consider disturbance >35% on high and moderate-suitability habitat (suitable habitat) within the RSA as a high magnitude effect. However, a >35% magnitude effect alone does not suggest a "significant" effect (i.e., measurable effect on population), as noted in the discussion above.

8.1.2 Wildlife Data Limitations

- There have been no site-specific marten or moose studies conducted in the RSA. Their occurrence, abundance, and distribution are inferred from nearby studies or similar habitat conditions. Bird information was limited to data collected on-site during one breeding season and information inferred from relevant studies on the same or similar species in similar habitats.

- No primary traditional knowledge information was collected for the wildlife assessment. Sources of traditional knowledge were limited to publicly available secondary sources cited in the baseline reports and assessment where appropriate.
- There are few studies on marten, moose, and birds in response to the proposed activities in the context of Eagle Plains' environmental conditions.

8.1.3 Input from Engagement on the Wildlife Assessment

- Marten was included as a VESEC because the Project overlaps with two trapping concessions, and the importance of the RSA to trappers (as it is associated with traditional lifestyle) was raised as an issue during community engagement (**Section 2.98**).
- Moose was included as a VESEC because the Project overlaps with moose habitat, and moose harvest (as it is associated with subsistence harvest) was raised as an issue during community engagement (**Section 2.98**).
- The Project's potential effects on birds were not explicitly raised as a concern during community engagement.
- Grizzly Bear was noted as another species that could occur in the RSA. While Chance acknowledges that Grizzly Bear were noted as important, as noted in **Section 3**, Grizzly Bear was not brought forward as a VESEC as there is little to no expected interaction with the proposed winter activities, and limited, intermittent interaction with individuals during seismic recording in the summer.

8.2 MARTEN

Marten was selected as a VESEC for the assessment of the Project due to their value as a furbearer to the Vuntut Gwitchin First Nation and to assess the potential Project effects on trapping resources (**Section 2.9.8**). The RSA occurs in the boreal taiga, at the northern limit of marten range (Buskirk and Ruggiero 1994, Yukon Ecoregions Working Group 2004). While marten occur over a contiguous range across northern North America from Labrador to Alaska (Snyder and Bissonette 1987, Buskirk and Ruggiero 1994, Drew 1995, Paragi et al. 1996), less is known about their basic ecology in northern boreal forest and taiga ecosystems than elsewhere (Latour et al. 1994). In more productive forests to the south, marten are often associated with mature forest structures, such as large trees, snags, and coarse woody debris (CWD; Buskirk and Ruggiero 1994, Thompson et al. 2012). Marten have not been assessed by the Committee on the Status of Endangered Wildlife in Canada (COSEWIC) for Federal listing.

The primary threat to marten populations is the fragmentation of mature and old-growth coniferous forests and the removal of large snags and coarse woody debris (Moriarty et al. 2011, Delheimer et al. 2019). However, there is some evidence that in northern boreal forests, marten exploit structural stages with short, stunted trees that are sparsely distributed (Latour et al. 1994, Paragi et al. 1996). Therefore, habitat selection patterns for marten in northern boreal and taiga ecosystems can differ from those described elsewhere in North America (Pretzlaw 2006), and this assessment was conducted in the relative context of this northern setting. The Project's baseline studies involved quantifying living habitat within the RSA using a habitat suitability index model (**Appendix 8-A**). Habitat values were assigned a suitability ranking of high, moderate, low, or very low/nil, relative to the range of habitat quality across the RSA. The majority of the RSA is comprised of Low-quality habitat (59.7%), followed by Moderate-quality habitat (23.1%), and a

limited amount of High-suitability habitat (15.9%) with Nil areas only accounting for approximately 1.3% (**Table 8-2**). The model indicated a mosaic of High, Moderate, and Low-quality marten habitat across the RSA, but with Moderate-quality habitat being widespread across the RSA.

Concentrations of High-suitability habitat were within the Enterprise and Dalglish creek watersheds in the south, a band running east-west north of the Dempster Highway, and the western part of the northern half of the RSA. High and Moderate-quality habitat is also concentrated in narrow strips of mature/old riparian forests along some of the major watercourses in the RSA, including Chance and Greaves creeks in the northwest and McParlon Creek west of the Dempster Highway.

8.2.1 Assessment Indicators and Parameters

The potential effects on marten include a change in habitat and mortality risk that may result from interactions with the Project. Marten movements are not anticipated to be affected by the Project's narrow seismic and infrequent encounters with well pads on a measurable scale. The effect of change in habitat was assessed quantitatively using a habitat suitability model, and mortality risk was evaluated qualitatively.

8.2.2 Project Interactions and Potential Effects

This subsection characterizes interactions between the Project and marten and describes the potential adverse effects.

8.2.2.1 Interactions

Interactions between marten and Project-related activities and components may result in a change in habitat (i.e., the direct loss of habitat and the indirect alteration of adjacent habitat) and mortality risk. Consequently, the potential effects of the interactions are carried forward into the assessment of the summary evaluation in this section. **Table 8-2** summarizes the potential interactions, and those interactions and effects are discussed in more detail below.

Table 8-2. Expected Interactions Between Marten and Project and the Resulting Potential Effects

Project Component / Activity	Change in Habitat	Mortality Risk
Engagement	0	0
Seismic Exploration	2	0
Drilling Exploration	2	0
Extended Flow Testing (EFT)	2	0
Well Maintenance (Workovers)	2	0
Access Roads	2	2
Mix Bury Cover (MBC) Construction and Operation	2	0
Central Processing Facility (CPF)	2	0
Airstrip Use	2	0
Water Withdrawal	2	0

Project Component / Activity	Change in Habitat	Mortality Risk
Transportation	2	2
Camp Use	2	1
Reclamation and Closure	2	1

Notes:
0 = no interaction
1 = minor interaction with marten is possible, but small immeasurable effect (e.g., possible slight behavioural response, no vegetation effects, no measurable effect on water quality). Designates a summary of effects addressed in the effects assessment as a discussion. This rating does not lead to the characterization of residual effects.
2 = substantial interaction with marten, designates a more detailed assessment of potential effects. Carry forward into residual effects characterization.

8.2.2.2 Change in Habitat

The construction of Project components (e.g., seismic lines, well pads, camp, and winter access roads) necessitates vegetation clearing within the Project footprint, potentially leading to direct habitat loss. Each work area is anticipated to require vegetation clearing once at the start of activity within the specific work area. The assessment of the effect, change in habitat, encompasses the entire operational period of the Project (i.e., 10 years).

Marten appear to respond to moderate habitat loss and fragmentation levels and can become absent from the landscape if the non-forest cover is >25% (Chapin et al. 1998, Hargis et al. 1999). Sensory disturbances associated with human activity, construction activity, and anthropogenic features (e.g., seismic lines) can also affect marten behaviour and habitat use (Zielinski et al. 2008, Siren 2013, Tigner et al. 2015, Slauson et al. 2017).

Vehicles and resource roads may result in sensory disturbances up to 50 m, and marten may avoid crossing active linear features over 13 m wide (Katnik 1992, Zielinski et al. 2008, Slauson et al. 2017). Additionally, marten avoid using seismic lines ≥3 m wide, increasingly avoid areas corresponding with increasing seismic line density, and completely avoid areas with a seismic line density of 20.8 km/km² (Tigner et al. 2015). Marten will use seismic lines ≤2 m wide and seismic lines ≥6 m, supporting at least some regeneration (Tigner et al. 2015).

Marten may decrease their use of suitable habitat in response to increasing human activity, up to complete avoidance in areas with high activity, with females more sensitive to human activity than males (Slauson et al. 2017). Marten may reoccupy suitable habitat within several months of the ending of human activity (Siren 2013, Slauson et al. 2017). Similarly, marten may gradually increase their use of suitable habitat following the end of a project's construction activity and the start of operations, although at lower levels than pre-construction (Siren 2013).

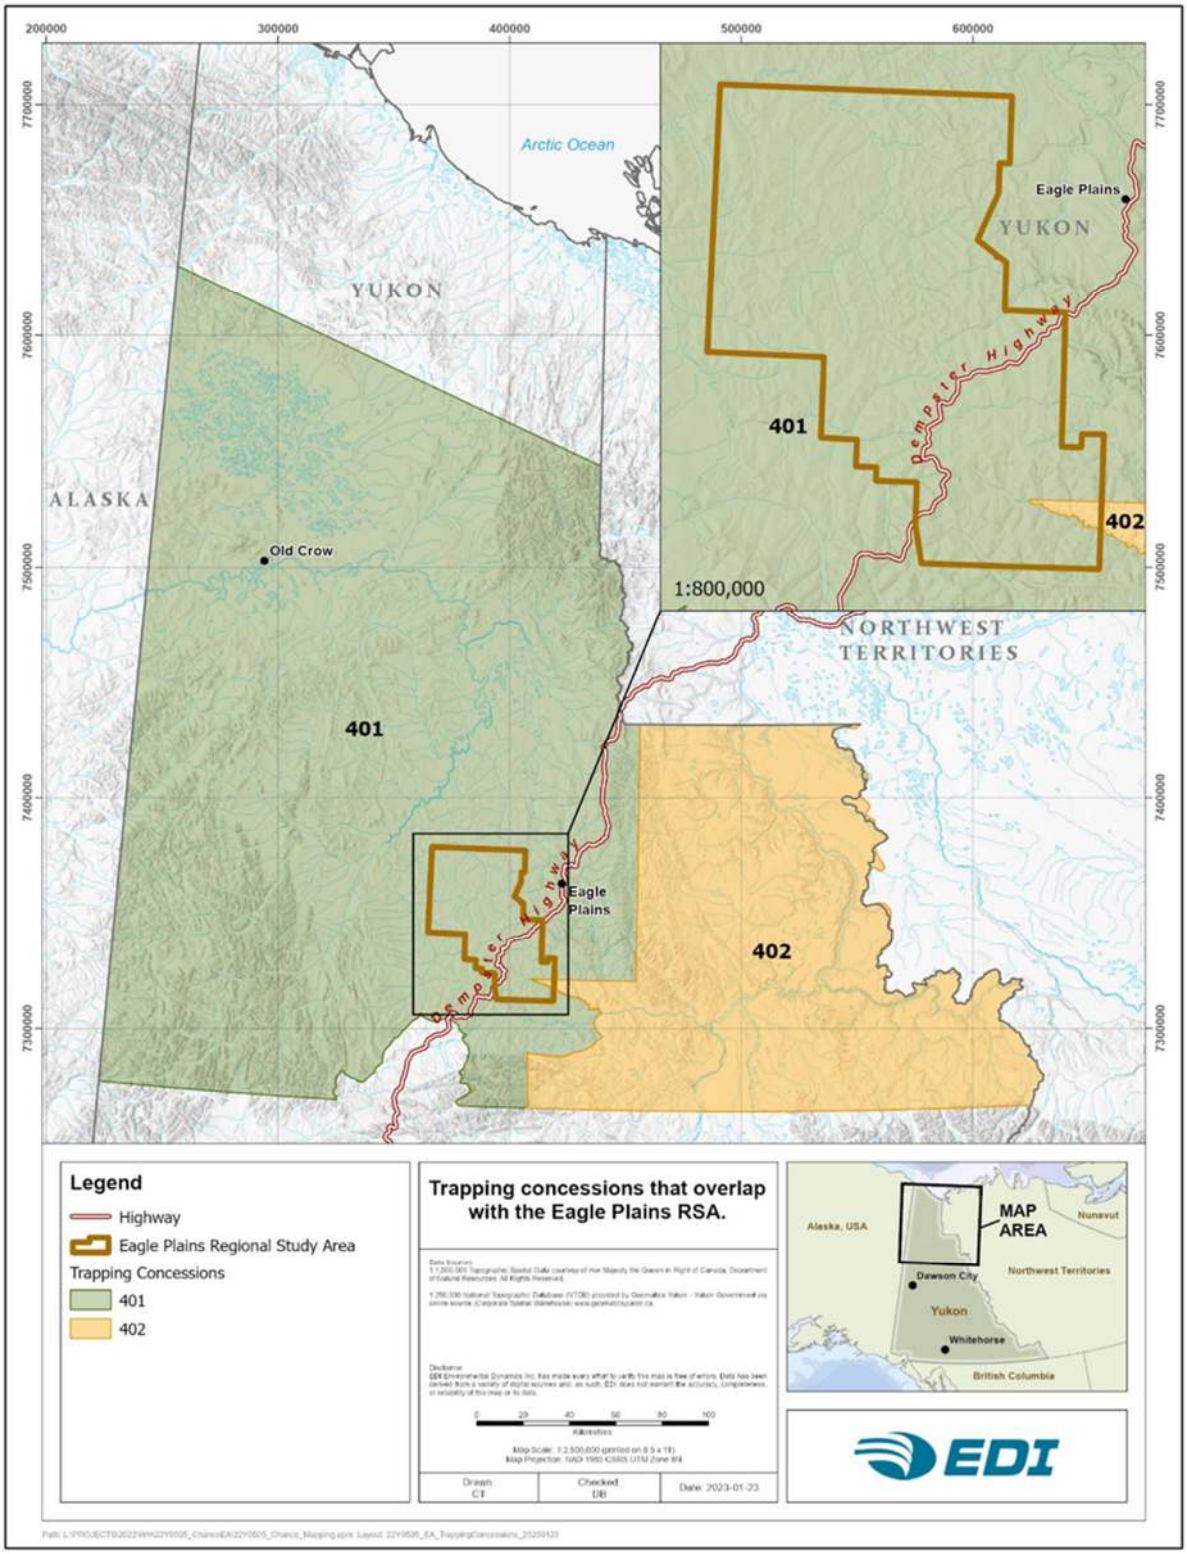
8.2.2.3 Change in Mortality Risk

Facilitating improved access for trapping and vehicle collision mortality are expected to be the primary sources of mortality risk from Project-related activities. Trapping can account for up to 90% of mortality in heavily trapped areas, whereas natural predation is the primary source of mortality in untrapped areas (Hodgman et al. 1994, 1997). Anthropogenic mortality can be compensatory with natural mortality in areas with sustainable marten harvest (Hodgman et al. 1994, Belant 2007).

Low reproductive rates and ease of trapping can make marten vulnerable to overharvesting in areas with easy road access (Hodgman et al. 1994). Increasing the number and density of roads can improve trappers' access, potentially increasing trapping effort and associated mortality risk for marten (Hodgman et al. 1994, Wiebe et al. 2013). Populations may decline if female survival, reproductive output, or immigration cannot compensate for high mortality rates (Hodgman et al. 1994).

In the Yukon, marten harvest is monitored via self-reporting by trappers within a concession. It is not directly monitored at the population level except in the Marten Conservation Area in the southern Yukon (Yukon Department of Environment 2022). Trapping quotas are used to build sustainable populations of marten in areas where overharvesting has been a concern (i.e., in the Marten Conservation Area) but not elsewhere, where trapping mortality is presumed to be sustainable (Slough and Smits 1985).

Marten were the most heavily trapped species (i.e., 715 reported harvested between 2012 – 2018) in the two group trapping concessions (401, 402) that overlap the RSA (**Map 8-1**). However, the annual marten harvest can vary considerably (i.e., 240 marten were harvested in 2015 compared to 0 harvested the following year), and the average annual harvest equals approximately one marten for every 847 km² of the combined concessions (**Figure 8-1**). A Yukon population density estimate of 0.6 marten/km² suggests that the number of harvested marten within the concessions is minimal compared to the overall population (Archibald and Jessup 1984).



Map 8-1. Trapping Concessions that Overlap with the Eagle Plains Regional Study Area

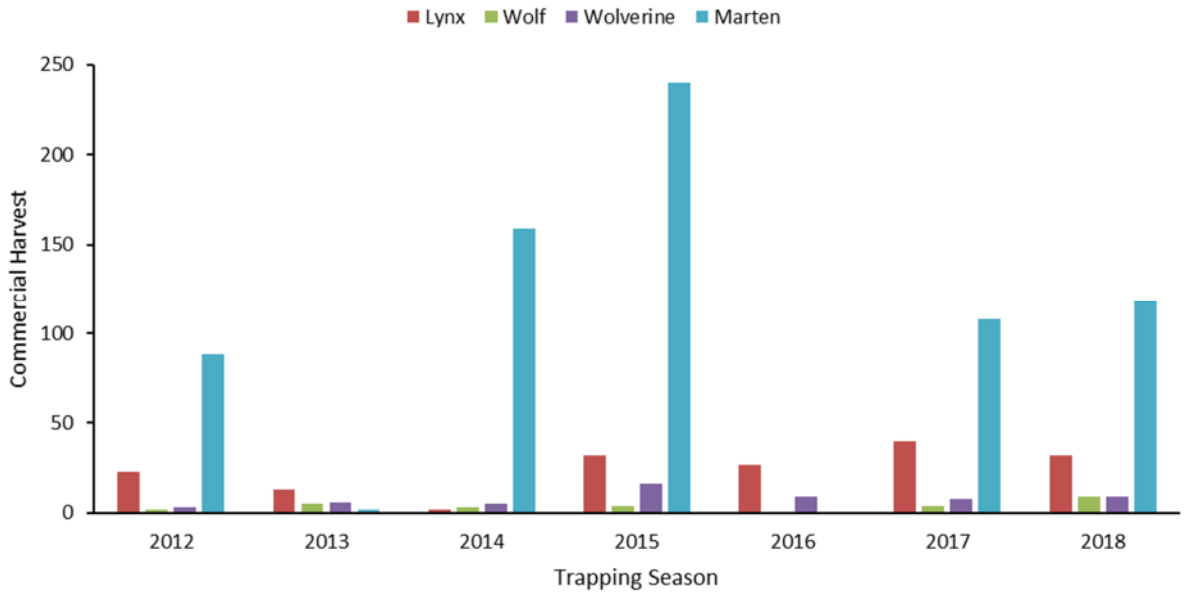


Figure 8-1. Commercial Harvest Returns for Group Trapping Concessions Overlapping the Regional Study Area for which Records were Available (Wall and Pinard 2023)

8.2.3 Mitigation Measures

Mitigation measures to avoid and minimize changes to marten habitat and mortality risk will be implemented as part of the Project design and during Project operations. Some mitigation measures may broadly apply to other wildlife species and other VESECs.

Mitigation measures to address both potential effects encompass several strategies, including:

- Minimizing the spatial extent of the Project and keeping activities (e.g., equipment use) within the Project footprint boundaries;
- Restrict most work activities to the winter aims to avoid when marten are denning with young;
- Increase the awareness of environmental and wildlife concerns through the development of a mandatory environmental orientation and policies for on-site personnel (e.g., use of wildlife reporting card, prohibition on pets); and
- Develop comprehensive plans addressing harmful substances, waste management, and traffic.

To the greatest extent possible, the environmental constraints mapping (**Section 3.3.2**) was used to avoid placing Project components (e.g., seismic lines, access roads) in suitable marten habitat. However, overlap with a small extent of suitable marten habitat is expected. To minimize and avoid changes in marten habitat and potential marten mortality, the Project will:

- retain potential denning trees (i.e., trees >30 cm in diameter at breast height with existing cavities or signs of decay) and coarse woody debris during vegetation clearing in suitable marten habitat where possible; and,
- to minimize changes to marten habitat and facilitate natural regeneration limit the clearing of vegetation to a height of 0.1 m high, except at the drill hole location and MBC sumps where

grubbing will occur, and to larger stumps along winter access roads to improve snow packing and subsequent safe driving conditions.

Snowbanks along road edges resulting from snow removal operations can create conditions that may hinder marten escape from access roads and increase mortality risk from vehicle collisions. Maintaining appropriately sized gaps in roadside snowbanks is expected to facilitate wildlife crossing, escape, and minimize mortality risk. Seismic lines are expected to decrease suitable marten habitat and the potential for increased facilitated trapping pressure. To reduce and avoid changes in marten habitat, the Project will:

- minimize line widths using Low Impact Seismic (LIS);
- use LIS in winter with snowpack that is expected to promote natural regeneration when Project activities are complete in a work area; and,
- maintain coarse woody debris along seismic lines, where possible.

Table 8-3 summarizes mitigation measures relevant to marten, organized by potential effect.

Table 8-3. Mitigation Measures Relevant to Marten and the Eagle Plains Exploration Project

Mitigation Measure	Potential Adverse Effect
Avoid or minimize the overlap of Project components with suitable marten habitat	Change in Habitat, Mortality Risk
Minimize the spatial extent of new components by using existing infrastructure (e.g., access roads, winter trails, seismic lines) wherever feasible	Change in Habitat, Mortality Risk
Delineate the Project footprint boundaries and restrict equipment use to within the defined areas	Change in Habitat, Mortality Risk
Conduct pre-clearance wildlife feature sweeps in suitable marten denning habitat before vegetation clearing and grubbing	Change in Habitat, Mortality Risk
Create and maintain species-specific no-work buffers around sensitive wildlife habitat features	Change in Habitat, Mortality Risk
Use winter access roads for Project-related activities to the extent practicable	Change in Habitat, Mortality Risk
Use buses or vans for transporting employees, visitors, and contractors as much as practical to reduce Project-related traffic	Change in Habitat, Mortality Risk
Prohibit workers from having domestic pets within the RSA	Mortality Risk
Prohibit workers, visitors, or contractors from feeding or harassing wildlife within the maximum disturbance footprint	Mortality Risk
Implement a wildlife orientation for all site personnel. The orientation will include information about potential Project effects on water, fish, vegetation and wildlife, potential wildlife crossings, wildlife mitigation measures, and waste management policies that limit human-wildlife interactions	Change in Habitat, Mortality Risk
Require workers to report all marten observations through a logbook or information directly passed to the on-site environmental lead	Change in Habitat, Mortality Risk
Develop a plan to prevent deleterious substances from entering a water body	Mortality Risk
Maintain all machinery on site in a clean condition and free of fluid leaks	Mortality Risk
Wash, refuel and service machinery in upland areas in such a way as to prevent any deleterious substances from entering a water body	Mortality Risk

Mitigation Measure	Potential Adverse Effect
Store fuel and other materials for the machinery in such a way as to prevent any deleterious substances from entering a water body	Mortality Risk
Establish a spill response plan with the following key mitigation measures: • report all spills as soon as possible when a deleterious substance enters a water body; • install containment measures around the spill; and, • collect and dispose of contaminated water or soil substrates using an emergency spill kit and other necessary spill response measures. Disposal will be at approved disposal facilities.	Change in Habitat, Mortality Risk
Directed lighting or light shielding at well sites and camps, rather than broad lighting, to focus lighting toward the ground in work areas	Change in Habitat
Allow for the regeneration of natural vegetation following the cessation of exploration in a work area	Change in Habitat
Clear vegetation for winter access roads down to the shrub level only (0.1 m in height)	Change in Habitat
Limit grubbing activities (i.e., removal of groundcover) to the drill hole location and the MBC sumps	Change in Habitat
Develop and implement an erosion and sediment control plan to prevent the introduction of sediment into any water body during all phases of the Project, undertakings and activities	Change in Habitat
Install erosion and sediment control measures, where appropriate, before beginning works, undertakings and activities	Change in Habitat
Maintain and inspect erosion and sediment control measures and structures regularly during all phases of the works, undertakings and activities	Change in Habitat
Keep the erosion and sediment control measures in place until all disturbed ground has been stabilized, then remove all erosion and sediment control materials (unless biodegradable)	Change in Habitat
Keep organic layers intact (i.e., limit grubbing and vegetation removal) wherever possible	Change in Habitat
Operate machinery on land in stable, dry areas	Change in Habitat
Monitor waterbodies regularly for signs of sediment entry during all phases of the works, undertakings and activities and take corrective action	Change in Habitat
Use biodegradable erosion and sediment control materials whenever possible	Change in Habitat
Minimize source line widths to 2.75 m and receiver line widths to 1.75 m and the total length of lines as much as possible (i.e., use as wide a spacing distance between lines as possible)	Change in Habitat
Maintain coarse woody debris along linear features where possible	Change in Habitat
Post and enforce a speed limit of 50 km/hr on Project-related access roads	Mortality Risk
Implement a policy to minimize disturbance of wildlife on access roads, including providing wildlife with the right-of-way on roads, not using vehicles to entice wildlife to move off the road, and slowing or stopping until wildlife have cleared the road	Mortality Risk

Mitigation Measure	Potential Adverse Effect
Maintain appropriately sized gaps of 300 m in roadside snowbanks to facilitate wildlife crossing and escape	Mortality Risk
Implement an on-site policy prohibiting workers from shooting, trapping, hunting, and fishing within the RSA	Mortality Risk
Prohibit workers from having personal firearms within the RSA	Mortality Risk
Investigate all Project-related wildlife mortality and correct the root cause(s) through adaptive management where possible.	Mortality Risk

8.2.4 Effects Characterization

8.2.4.1 Approach

Residual effects on marten are characterized following those described in the Methods Section (**Table 8-1**), including consideration of magnitude, likelihood, geographical extent, duration, frequency, timing, reversibility, context, and confidence of the effect. The ratings and definitions for each residual effect characteristic are in **Table 8-1** and discussed explicitly in the relevant sections below.

8.2.4.2 Residual Change in Habitat Effects

The Project may affect the amount of suitable marten habitat in the RSA, resulting in a change in habitat abundance. The assessment of change in habitat considers the quantitative direct loss of marten habitat across the range of the 10 footprint scenarios and a qualitative assessment of the indirect alteration (e.g., sensory disturbances, edge effects, perceived barriers). Direct habitat loss was quantified by calculating the area of suitable marten habitat potentially lost to seismic, well pad and access road clearing within the RSA. The change in suitable habitat under each scenario was then compared with the amount of baseline suitable habitat for each rating category, resulting in a range of estimated changes in habitat for each rating (i.e., footprint scenarios − baseline).

Indirect effects from sensory disturbance can affect marten habitat use and may extend up to 50 m from areas of human presence and vehicle use. As a result, it is expected that marten may show short-term avoidance of areas with higher traffic levels and human presence. It is anticipated that this will be limited to small areas of the Project footprint due to the dispersed spatial and temporal activities of the Project and the limited amount of work outside of the winter. In addition, it is expected that marten will resume use of these areas following the ending of Project activities in an area, and the duration of the effect is predicted to be short-term.

After assessing the different footprint scenarios, it is expected that the Project will likely reduce the suitable marten habitat within the RSA (**Table 8-4**). High-quality habitat might decrease by up to 1.75%, and Moderate-quality habitat might decrease by 0.07%, with little to no difference among the well site scenarios.

Table 8-4. Change in Marten Habitat in the Eagle Plains Regional Study Area Based on Assessing the 10 Footprint Scenarios

Habitat Rating	Habitat Suitability Index Scores	**Baseline**		Footprint Scenarios (n = 10)		**Potential Change (n = 10)**	
		Area (ha)	Area (%)	Range (ha)	Range (%)	Range (ha)	Range (%)
High	>0.75 to 1.0	38,050	15.9	33,865to 33,886	14.2 to 14.2	−4,164 to −4,185	−1.7 to −1.8
Moderate	>0.50 to 0.75	55,202	23.1	55,037 to 55,064	23.1 to 23.1	−138 to −165	−0.1 to −0.1
Low	>0.25 to 0.50	142,485	59.7	137,243 to 137,271	57.5 to 57.5	−5,213 to −5,242	−2.2 to −2.2
Nil/Very Low	>0.0 to 0.25	3,016	1.3	12,563 to 12,586	5.3 to 5.3	9,548 to 9,570	4.0 to 4.0
Total		238,752	100.0				

Table 8-5 summarizes the residual effects characteristics and ratings, with rationale, for the predicted effects on habitat. High and moderate-rated marten habitat (i.e., suitable habitat) might decrease by up to 1.75% and 0.07%, respectively. Therefore, the magnitude of habitat change is low due to a <11% change in habitat from baseline conditions.

The Duration is expected to be long-term, as suitable habitat is anticipated to require 30–90 years to regenerate. However, sensory disturbances that may result in habitat alteration are expected to occur continuously throughout the life of the Project. Habitat loss is expected to occur as multiple irregular events as work areas change annually and clearing occurs in different areas of the seismic program.

Habitat alteration is expected to end following the completion of exploration and associated reclamation, and the regeneration of natural vegetation is expected to reverse the loss of habitat. Therefore, the potential residual effect on habitat and mortality risk is reversible.

Table 8-5. Characterization of Potential Project Effects on Marten Habitat

Criterion		**Rating**	**Rationale**
Magnitude		Low	The potential change in the amount of suitable habitat across the RSA is <11%. Vegetation clearing, including trees, is expected to be required for access roads and seismic lines.
Likelihood		Probable	Mitigation measures are expected to minimize but not eliminate the potential for change in habitat.
Geographic Extent		Local	Changes in habitat alteration due to Project-related sensory disturbances are predicted to be limited to the zone of influence (ZOI). Direct habitat loss is predicted to be limited to the maximum disturbance area.
Duration, Frequency and Timing	Duration	Long-term	A change in habitat is predicted to occur throughout the entire exploration period of the Project. However, affected habitat is expected to require 30 – 90 years to regenerate.

Criterion		Rating	Rationale
	Frequency	Continuous	Habitat loss will likely occur once in each work stage; however, habitat alteration through sensory disturbances is expected to occur continuously during the winter Project activities.
	Timing	Year-round	The residual effect of that vegetation clearing is predicted to remain year-round until vegetation has regenerated.
Reversibility		Reversible	The alteration of habitat is expected to end following the completion of exploration and associated reclamation. The regeneration of natural vegetation is expected to reverse habitat loss.

8.2.4.2.1 Context and Confidence

The RSA overlaps with the Zone IV Integrated Management Area (IMA) in the North Yukon and Peel Watershed Planning Regions. This zone is an area of diminished ecological and cultural values in a moderately sensitive biophysical setting and allows for the highest level of development. Cumulative effect indicators are used in both plans to determine if the current management and development are meeting the set goals and objectives. Two cumulative effects indicators included in the Plans are direct surface disturbance and linear density, with guidelines setting cautionary (0.75 km/km²) and critical (1.0 km/km²) indicator levels in both plans.

A network of linear features was previously created in parts of the RSA resulting from intermittent historical exploration activities. The Linear Feature Study (**Appendix 8-B**) determined the extent and characteristics of liner features in the RSA and addressed three objectives:

3. comprehensive mapping and classification of existing linear feature footprints within the RSA;
4. quantification of structural aspects (e.g., widths) and functional aspects (ease of travel and sightlines) of linear features; and,
5. quantification of regeneration pathways and structural stages of linear features.

This combined information supports assessing the Project's potential effects of linear features and refinement of mitigation measures for linear features to minimize possible effects. After accounting for natural features and regeneration, the adjusted linear feature density for the RSA was below the cautionary and critical indicator levels, at 0.52 km/km², in both regional land use plans.

The level of confidence in this prediction is Moderate (**Table 8-6**). The direct effects on marten habitat loss and alteration are documented in various studies, and the efficacy of mitigation measures has been supported through application on other and similar projects. However, there is some uncertainty in the specific context of those studies and the habitat conditions at Eagle Plains.

Table 8-6. Characterization of Context and Confidence in the Residual Project Effects on Marten Habitat

Criterion	Rating	Rationale
Context	Highest Development	The Project occurs within the IMA Zone IV Management Unit, designated as the highest level of disturbance.
Confidence	Moderate	Mitigation measures are expected to effectively avoid and minimize the changes in habitat; however, the uncertainty of the Project footprint results in Moderate Confidence in the residual effect prediction.

8.2.4.3 Residual Mortality Risk Effects

The Project may affect the risk of mortality for marten in the RSA and the assessment of this residual effect considers a qualitative assessment of the change in mortality risk. **Table 8-7** summarizes the residual effects characteristics and ratings, with rationale, for the predicted effects on mortality risk. Changes in mortality risk are expected to remain within baseline conditions given traffic controls and likely unrealized increased trapper access. Therefore, the magnitude of mortality risk is low due to likely unmeasurable changes from natural and pre-existing mortality risk conditions. Project-related access roads and seismic lines may facilitate trapping access within the RSA, therefore the geographic extent is Regional. The duration is expected to be medium-term, as changes to mortality risk are expected to occur continuously throughout the life of the Project.

Any changes in mortality risk are expected to end following the completion of exploration and associated reclamation. Therefore, the potential residual effect on mortality risk is reversible.

Table 8-7. Characterization of Potential Project Effects on Marten Mortality Risk

Criterion		Rating	Rationale
Magnitude		Low	The change in mortality risk is predicted to remain within natural variation.
Likelihood		Probable	Mitigation measures are expected to minimize but not eliminate the potential for mortality risk.
Geographic Extent		Regional	Changes in mortality risk are predicted to be associated with facilitated access to the RSA.
Duration, Frequency and Timing	Duration	Medium-term	A change in mortality risk is predicted to occur throughout the entire exploration period of the Project.
	Frequency	Continuous	Changes in mortality risk are expected to occur continuously during the winter Project activities.
	Timing	Winter	Project activities and disturbance is predicted to primarily occur in winter.
Reversibility		Reversible	Change in mortality risk is expected to end following the completion of exploration and associated reclamation.

8.2.4.3.1 Context and Confidence

The RSA overlaps with the Zone IV IMA in the North Yukon and Peel Watershed Planning Regions. This zone is an area of diminished ecological and cultural values in a moderately sensitive biophysical setting

and allows for the highest level of development. The level of confidence in this prediction is High (**Table 8-8**). The effect on marten mortality risk is documented and the efficacy of mitigation measures has been supported through application on other and similar projects.

Table 8-8. Characterization of Context and Confidence in the Residual Project Effects on Marten Mortality Risk

Criterion	Rating	Rationale
Context	Highest Development	The Project occurs within the IMA Zone IV Management Unit, designated as the highest level of disturbance.
Confidence	High	Mitigation measures are expected to effectively avoid and minimize mortality risk

8.2.5 Significance

- The potential change in high and moderate-quality marten habitat (<2%) is not expected to affect the long-term viability of the marten population within the RSA due to:
- The amount of anticipated habitat loss is below the level where marten populations become absent from a region (i.e., <25%);
- The timeframe until vegetation regeneration is predicted to occur and can become habitat; and,
- The amount of time Project activities may occur within an area and the length of time until marten usually reoccupy habitat.

As a result, the Project has been assessed as unlikely to change marten habitat or mortality risk to the point of altering their integrity within the RSA to the point where the regional marten population is unsustainable.. Therefore, the residual effects are **not significant**.

8.2.6 Cumulative Effects Assessment

8.2.6.1 Approach

Project-related residual effects on marten with the potential to interact with residual cumulative effects of past, present and reasonably foreseeable projects and activities within or extending into the Cumulative Effects Study Area (CESA) are:

- change in habitat; and,
- mortality risk.

The spatial boundaries of the Cumulative Effect Assessment (CEA) on marten are delineated by the CESA as described in **Section 3.1.6.1.1**. Projects and activities outside the CESA but with potential effects within this area were also included in this assessment. Temporal boundaries for assessing cumulative effects encompass past, present, and reasonably foreseeable future activities spanning the Project's lifespan (**Section 1.3.1**).

8.2.6.2 Cumulative Change in Habitat Effect

The assessment of the cumulative effect on marten used the indicator of total surface disturbance (area [km²] and percent [%]) from anthropogenic footprints (e.g., mineral exploration, oil and gas) disturbed by

the footprints for its characterization. Present conditions include a total area of 62.5 km² (0.6%) disturbed by past and present projects and activities within the CESA (**Table 8-9**). This is predicted to increase in the future by 1.2 km² (0.0%) following the inclusion of reasonably foreseeable projects and activities. The Project is expected to increase the amount of disturbed area over the existing conditions by a maximum of 69.5 km² (0.6%) within the CESA, resulting in a maximum disturbed area of 133.2 km² (1.2%) when combined with past, present, and reasonably foreseeable projects and activities.

The magnitude of cumulative change in habitat effects is low, as the total surface disturbance is <1% over existing conditions. The likelihood of the cumulative effect is probable due to mitigation measures minimizing but not eliminating the potential of the effect. The cumulative effect is expected to be regional in geographic extent, with changes in habitat occurring throughout the CESA as a result of projects and activities part of the assessment. The duration of the effect is expected to occur over the medium-term, as the effect is predicted to end following the completion of projects and activities in an area. The frequency of a change in habitat is expected to be continuous, as vegetation clearing is anticipated to occur occasionally, but its effects on habitat are predicted to continue until vegetation regenerates. The Timing of the effect is predicted to occur year-round as projects and activities within the CESA are expected to result in a change in habitat throughout the year. Over time, it is predicted that the regeneration of the affected habitat will likely occur following the completion of projects and activities, and it is anticipated to reverse the cumulative effect. A summary of the characteristics of the cumulative effects of change in habitat is provided in **Table 8-10**.

Table 8-9. Cumulative Change in Habitat Effects from Existing and Project-Related Disturbances on Marten

Cumulative Effect Indicator	Scenario	Cumulative Effects Study Area
Total Surface Disturbance (Footprints)	Present	62.5 km² (0.6%)
	Project	69.1–69.5 km² (0.6%)
	Future	1.2 km² (0.0%)
	Total Cumulative Effect	132.8–133.2 km² (1.2%)

Table 8-10. Characterization of Cumulative Change in Habitat Effects on Marten

Criterion		Rating	Rationale
Magnitude		Low	The change in habitat across the CESA is predicted to be <1% over existing conditions.
Likelihood		Probable	Mitigation measures are expected to minimize but not eliminate the potential for a change in habitat.
Geographic Extent		Regional	Change in habitat quality is expected to occur across the CESA due to the location of the projects and activities.
Duration, Frequency and Timing	Duration	Medium-term	The effect is expected to end following the completion of projects and activities in an area.
	Frequency	Continuous	Vegetation clearing required for projects and activities will likely occur occasionally, but the cumulative effect on marten is predicted to be continuous until vegetation regenerates.
	Timing	Year-round	The effect is expected to occur year-round due to changes in habitat remaining until vegetation regeneration.
Reversibility		Reversible	The regeneration of affected habitat is expected to be reversible over time.

8.2.6.2.1 Context and Confidence

The assessment of the cumulative change in habitat effects on marten considered the context of Regional Land Use Planning and the confidence in accurately quantifying and predicting those effects (**Table 8-11**). The characterization of effects is consistent with the Land Use Plans' objectives, and there is relatively high confidence that effects were accurately captured in the assessment. Some anthropogenic features may not have entirely been accounted for in the total disturbance calculation; however, there is a high degree of confidence that most disturbances were included. Therefore, the confidence in this CEA is high.

Table 8-11. Characterization of Context and Confidence in the Assessment of Cumulative Change in Habitat Effects on Marten

Criterion	Rating	Rationale
Context	Conforms to Regional Land Use Plans	Land Management Unit IV zones of the North Yukon and Peel Regional Land Use Plans are areas zoned for the highest level of development. The Project activities are consistent with the integrated resource management objectives of the LUPs.
Confidence	High	There is high confidence in characterizing the cumulative effect and its persistence. A precautionary approach was taken to quantify the change in habitat effect.

8.2.6.3 Cumulative Mortality Risk Effect

Cumulative mortality risk effects result from linear features across the landscape, with higher linear feature densities (km/km²) that can support facilitated predation of marten by human trappers. Therefore, linear feature density was used to assess cumulative mortality risk effects. Linear feature density was calculated as the total length of linear features divided by the size of the CESA.

Due to the Project, linear feature density is expected to increase by 2.2 km/km² in the CESA and between 0.0–2.3 km/km² in the trapping concessions overlapping the CESA relative to existing conditions. The maximum increase in linear feature density occurs due to the Project is approximately 25,090 km of additional linear features. A summary of the cumulative effect indicator for mortality risk effects is provided in **Table 8-12.**

The magnitude of the cumulative effect is predicted to be high due to the expected increase of >35% over existing conditions in the overall linear feature density. The cumulative effect is probable due to mitigation measures minimizing but not eliminating the Likelihood of the effect. The effect is anticipated to be regional in geographic extent, as it may occur throughout the CESA due to the projects and activities that were part of the assessment. The duration of the effect is expected to occur over the medium-term as risk is expected to end following the completion of projects and activities in an area. The frequency of mortality risk is anticipated to be continuous as conditions could exist within a given year that would facilitate trapping access along linear features. The timing of the effect is expected to occur year-round as projects and activities within the CESA are expected to result in mortality risk throughout the year. Over time, it is predicted that mortality risk will likely end following the completion of projects and activities in an area and will likely reverse the cumulative effect. A summary of the characteristics of the cumulative mortality risk effect is provided in **Table 8-13**.

Table 8-12. Cumulative Mortality Risk Effects from Existing and Project-Related Disturbances on Marten

Cumulative Effect Indicator	Condition	Cumulative Effects Study Area	Trapping Concession 387	Trapping Concession 401	Trapping Concession 402
Linear Feature Density	Present	0.8 km/km² (8,716.3 km)	0.4 km/km² (34.6 km)	0.8 km/km² (8,616.6 km)	0.2 km/km² (65.1 km)
	Project	2.2 km/km² (25,030.7–25,090.6 km)	0.0 km/km² (0.0 km)	2.3 km/km² (24,772.3–24,832.2 km)	0.6 km/km² (258.4 km)
	Future	0.0 km/km² (83.6 km)	0.0 km/km² (0.0 km)	0.0 km/km² (83.6 km)	0.0 km/km² (0.0 km)
	Total Cumulative Effect	3.0 km/km² (33,830.6–33,890.5 km)	0.4 km/km² (34.6 km)	3.1 km/km² (33,472.5–33,532.4 km)	0.8 km/km² (323.5–323.5 km)

Table 8-13. Characterization of Cumulative Mortality Risk Effects on Marten

Criterion		Rating	Rationale
Magnitude		High	The increase in linear feature density due to the Project is expected to be >35%.
Likelihood		Probable	Mitigation measures are expected to minimize but not eliminate mortality risk.
Geographic Extent		Regional	Changes in mortality risk are expected to occur across the CESA due to the location of the projects and activities.
Duration, Frequency and Timing	Duration	Medium-term	A change in mortality risk is predicted to end following the completion of projects and activities in an area.
	Frequency	Continuous	Conditions may exist that could lead to mortality risk occurring continuously along snow-packed linear features.
	Timing	Year-round	Mortality risk is expected to occur year-round.
Reversibility		Reversible	The mortality risk is expected to be reversible following the cessation of projects and activities.

8.2.6.3.1 Context and Confidence

The assessment of the cumulative mortality risk effects on marten considered the context of Regional Land Use Planning and the confidence in accurately quantifying and predicting those effects (**Table 8-14**). The characterization of effects is consistent with the Land Use Plans' objectives, and there is relatively high confidence that effects were accurately captured in the assessment. It is possible that some anthropogenic features were not included in the linear feature density calculation; however, there is a high degree of confidence that most disturbances were included. Therefore, the confidence in this CEA is high.

Table 8-14. Characterization of Context and Confidence in the Assessment of Cumulative Mortality Risk Effects on Marten

Criterion	Rating	Rationale
Context	Conforms to Regional Land Use Plans	Land Management Unit IV zones of the North Yukon and Peel Regional Land Use Plans (LUPs) are areas zoned for the highest level of development. The Project activities are consistent with the integrated resource management objectives of the LUPs.
Confidence	High	There is high confidence in the characterization of the cumulative effect and its persistence. A precautionary approach was taken to quantify the change in habitat effect.

8.3 MOOSE

Moose are a large ungulate with conservation, cultural, and economic importance in the Yukon. They occur across the Northern Hemisphere and the Yukon, except where absent in the far southwest (Geist et al. 1999, Government of Yukon 2019, 2022a). The overall Yukon population is estimated to be 70,000, and an

average density of 100 to 250 moose per 1,000 km² of suitable moose habitat (Government of Yukon 2019, O'Donoghue 2020).

Moose use seasonal home ranges, moving between them typically in response to environmental conditions and reproductive status (Clarke et al. 2017, Government of Yukon 2022b). Winter is the most limiting season for moose in the Yukon. A moose winter forage habitat suitability model was developed for the RSA (**Appendix 8-A**). High-suitability moose winter habitat is limited across the RSA, most commonly associated with riparian areas, but Moderate-suitability habitat is extensive. Although moose are likely to select the High-suitability areas preferentially, a substantial amount of total winter forage appears to occur within large areas with relatively low willow cover (i.e., the Moderate-suitability areas).

Due to the scattered occurrence of High-suitability habitats across the RSA, some moose are expected to occur across the RSA in winter. However, local densities of moose are likely to vary within the portions of Low and Moderate-suitability habitats that form the habitat matrix at a larger scale.

A habitat suitability model was developed to quantify winter foraging habitat for moose within the RSA (**Appendix 8-A**). The model used a 4-class system categorical rating scheme (High, Moderate, Low, Nil), reflecting knowledge of the species' ecology and habitat use (Resources Inventory Committee 1999).

High-suitability winter moose habitat (7.1%) is limited, and Moderate-suitability habitat makes up the majority of the RSA (60.9%), followed by Low-suitability habitat (31.2%), and with Nil areas only accounting for approximately 0.8% of the RSA (**Table 8-15**). The distribution of winter moose habitat shows clear spatial patterns across the RSA. High-suitability habitat is found scattered across the RSA, generally in much smaller patches than areas of Moderate and Low. High-suitability areas are often in narrow riparian strips along streams, non-confined drainage areas, and some areas of upland deciduous and mixed-wood forest. Areas of Moderate habitat are concentrated in the southern half of the RSA and along the western and northern boundary in the northern portion of the RSA.

The pattern of having a relatively large portion of the landscape in Moderate-suitability winter habitat is different than in other parts of the Yukon, especially in more mountainous areas, where High and Moderate-suitability winter habitats are often constrained by elevation, snow depths and greater distribution of diverse vegetation communities (McCulley et al. 2017). Moderate and Low rated habitats likely provide a substantial proportion of total winter forage for moose in the RSA due to the large extent that Moderate and Low-suitability habitats cover. In Eagle Plains, the overall distribution of winter foraging habitat for moose appears to be distributed in relatively low levels across large portions of the RSA versus concentrated in relatively small portions of the landscape, typical in more mountainous parts of Yukon.

8.3.1 Assessment Indicators and Parameters

The potential effects on moose include a change in habitat and mortality risk that may result from interactions with the Project. The Project can affect moose habitat by clearing vegetation, causing sensory disturbance, and posing mortality risks by providing human and predator access to moose habitat during winter. A habitat suitability model quantified Project-related effects of a change in habitat. The predicted residual effect of change in mortality risk was assessed qualitatively.

8.3.2 Project Interactions and Potential Effects

This subsection characterizes interactions between the Project and moose and describes the potential adverse effects.

8.3.2.1 Interactions

Interactions between moose and Project-related activities and components may result in a change in habitat (i.e., the direct loss of habitat and the indirect alteration of adjacent habitat) and mortality risk. Consequently, the potential effects of the interactions are carried forward into the assessment of the summary evaluation in this section **Table 8-15** summarizes the potential interactions, and those interactions and effects are discussed in more detail below.

Table 8-15. Expected Interactions Between Moose and the Eagle Plains Exploration Project and the Resulting Potential Effects

Project Component / Activity	Change in Habitat	Mortality Risk
Engagement	0	0
Seismic Exploration	2	0
Drilling Exploration	2	0
Extended Flow Testing (EFT)	2	0
Well Maintenance (Workovers)	2	0
Access Roads	2	0
Mix Bury Cover (MBC) Construction and Operation	2	0
Central Processing Facility (CPF)	2	0
Airstrip	2	0
Water Withdrawal	2	1
Transportation	2	2
Camp	2	0
Reclamation and Closure	2	2

Notes:
0 = no interaction
1 = minor interaction with moose possible, but small immeasurable effect (e.g., possible slight behavioural response, no vegetation effects, no measurable effect on water quality). Designates a summary of effects that are addressed in the effects assessment as a discussion. This rating does not lead to the characterization of residual effects.
2 = substantial interaction with moose, designates a more detailed assessment of potential effects. Carry forward into residual effects characterization.

8.3.2.2 Change in Habitat

Vegetation clearing required to construct Project components (e.g., winter access roads, seismic lines, and staging areas) may result in direct habitat loss within the maximum disturbance footprint. Moose may exhibit reduced habitat use in response to diminishing habitat patch size, heightened spatial separation between patches, and alterations in patch configuration (Stewart and Komers 2012).

Habitat alteration due to sensory disturbances will likely be limited to the annual work area during vegetation clearing and seismic activity. Sensory disturbances associated with Project components and activities (e.g., anthropogenic noise, vehicle traffic, human presence) may alter moose use of habitat within a 250 m zone of influence (ZOI) of Project components (Dussault et al. 2006, Lykkja et al. 2009, Neilson and Boutin 2017).

Sensory disturbances associated with Project components and activities (e.g., vehicle traffic, human presence) may alter moose use of adjacent habitat. Vehicle traffic can negatively influence moose habitat selection with increasing traffic volumes, although roads with less than 10 vehicles/day typically do not affect moose habitat use (Laurian et al. 2008, Wattles et al. 2018). Road presence can affect moose habitat selection in the surrounding areas up to 1,000 m, although most effects occur within 250 m of a road (Colescott and Gillingham 1998, Yost and Wright 2001, Laurian et al. 2008, Shanley and Pyare 2011).

Moose may avoid areas of high human activity, although females with calves may also avoid areas of low human activity (Lykkja et al. 2009). Moose cows, particularly those with calves, strongly avoid areas with a high intensity of grey wolf (*Canis lupus*) use, which may include linear features associated with developing surrounding natural resources (Neilson and Boutin 2017). Habitat alteration from sensory disturbance will likely result in the downgrading of habitat up to 250 m away from Project components and activities and reduce the overall amount of Moderate and High rated habitat.

8.3.2.3 Change in Mortality Risk

Primary sources of mortality risk for moose from Project-related activities may include vehicle collisions and increased or easier hunter and predator access. It is expected that if any changes in Project-related moose mortality risk occur, they would likely be limited to active work areas. However, mitigation measures are expected to limit interactions between Moose and potential sources of direct mortality, thereby minimizing the potential effect of change in mortality risk. The annual harvest is lower within Yukon game management zone 1, where the Project is located, than in other management zones. It ranged from 0 to 10 individuals annually from 1980 – 2014, and 43% of the years, no harvest was recorded (Milligan 2018). It is expected that any changes in moose mortality risk from easier hunting access is expected to be minimal due to the low annual harvest. Linear features can facilitate movement by predators and increase mortality risk (Serrouya et al. 2016, Dickie et al. 2017b). The Project is minimizing the development of new linear features by reactivating historical winter access roads and using three-dimensional (3D) seismic lines. These linear features are selected less frequently by predators (e.g., grey wolf) and have decreased movement rates compared to two-deimensional (2D) seismic lines (Dickie et al. 2017a). As a result, any changes in mortality risk due to ease of predator access are expected to be minimal.

The increased mortality risk is possible through vehicle collisions and the potential for improved harvester access. Estimates for moose vehicle collisions (MVCs) are typically only available for highways and primary roads. An unknown number of mortalities may occur along resource roads (Child et al. 1991, Sielecki 2010). MVCs are typically most common during winter (i.e., December to February) and most frequently just after sunset and before sunrise, but typically only in areas where the surrounding snowpack depth is less than 100 cm (Sielecki 2010, Cunningham et al. 2022).

Moose may also avoid deeper snow depths and select roads cleared of snow to facilitate travel, increasing the likelihood of MVC (Cunningham et al. 2022). Other factors such as areas with higher moose use that overlap with roads (i.e., valley bottoms), poor light conditions, traffic speed exceeding 80 kilometres per hour (km/hr) and amount of vehicle traffic, and tall or extended snowbanks along road edges may influence

the risk of MVC (Stuart 1984, Child et al. 1991, Joyce and Mahoney 2001, Dussault et al. 2006, Danks 2007, O'Keefe and Rea 2012). Anthropogenic features (e.g., roads, seismic lines) can facilitate the ease of hunter and predator travel, increasing the accessibility into areas and resulting in indirect sources of mortality (Beazley et al. 2004, Ewacha 2016, Mumma and Gilligham 2019).

8.3.3 Mitigation Measures

Mitigation measures will be implemented as part of the design of the Project and during Project activities to avoid and minimize changes in moose habitat and mortality risk. Some mitigation measures may broadly apply to other VESECs, whereas others may be only to moose. Measures may also be applicable to both potential effects or each individually.

Mitigation measures to address both potential effects involve several strategies. Minimizing the spatial extent of the Project, delineating and limiting equipment use and directed lighting to within Project footprint boundaries, and using existing winter access roads. Restricting most work activities during winter is intended to avoid the moose calving season. For on-site personnel, mandatory environmental orientation, the use of wildlife reporting cards, and prohibitions on pets, firearms, hunting, and harassment will be enforced. Additionally, comprehensive plans addressing harmful substances, waste management, and traffic are expected to minimize further and avoid changes to moose habitat and mortality risk.

The environmental constraints mapping (**Section 3.3.2**) incorporates avoidance of high-value moose forage habitat in Project design to minimize and avoid changes in moose habitat. The Project will avoid locating mix bury and cover sites, and borrow pits in high-value winter moose forage habitats to the extent possible. However, overlap with a small extent of high-value winter moose habitat is expected. To minimize changes to moose habitat and facilitate natural regeneration, vegetation clearing will be limited to a height of 0.1 m high, except at the drill hole location and MBC sumps where grubbing will occur, and to larger stumps along winter access roads to improve snow packing and subsequent safe driving conditions. A plan to address potential erosion and sediment control concerns will be developed that is anticipated to avoid and minimize changes in moose habitat.

Snow banks along road edges resulting from snow removal operations can create conditions that may hinder moose escape from roads and increase mortality risk from vehicle collisions. Maintaining appropriately sized gaps, approximately every 300 m, in roadside snowbanks is expected to facilitate wildlife crossing, escape, and minimize mortality risk. Seismic lines are expected to result in a small increase in moose foraging habitat; however, there is the potential for increased facilitated predation by natural predators and humans. To minimize and avoid mortality risk, the Project will:

- increase the tortuosity of curves along seismic lines (to reduce sightlines and ease of travel);
- minimize the total length of lines as much as possible (i.e., use as wide a spacing distance between lines as possible);
- minimize line widths to ≤5 m; and,
- create vegetation barriers (e.g., sharp-angle 'dogleg' bends, vegetation piling) along lines where they enter the high-value habitat, and at least every 300 m within the habitat areas, to impede predator and human travel.

All mitigation measures applicable to moose, organized by potential effect is summarized in **Table 8-16**.

Table 8-16. Mitigation Measures Relevant to Moose and the Eagle Plains Exploration Project

Mitigation Measure	Potential Adverse Effect
Avoid or minimize the overlap of Project components with suitable moose habitat	Change in Habitat, Mortality Risk
Minimize the spatial extent of new components by using existing infrastructure (e.g., access roads, winter trails, seismic lines) wherever feasible	Change in Habitat, Mortality Risk
Delineate the Project footprint boundaries and restrict equipment use to within the defined areas	Change in Habitat, Mortality Risk
Use winter access roads for Project-related activities to the extent practicable	Change in Habitat, Mortality Risk
Use buses or vans for transporting employees, visitors, and contractors as much as practical to reduce Project-related traffic	Change in Habitat, Mortality Risk
Directed lighting or light shielding at well sites and camps, rather than broad lighting, to focus lighting toward the ground in work areas	Change in Habitat, Mortality Risk
Prohibit workers from having domestic pets within the RSA	Change in Habitat, Mortality Risk
Prohibit workers, visitors, or contractors from feeding or harassing wildlife within the maximum disturbance footprint	Change in Habitat, Mortality Risk
Implement a wildlife orientation for all site personnel. The orientation will include information about potential Project effects on water, fish, vegetation and wildlife, potential wildlife crossings, wildlife mitigation measures, and waste management policies that limit human-wildlife interactions	Change in Habitat, Mortality Risk
Require workers to report all moose observations through a logbook or information directly passed to the on-site environmental lead	Change in Habitat, Mortality Risk
Develop a plan to prevent deleterious substances from entering a water body	Change in Habitat, Mortality Risk
Maintain all machinery on site in a clean condition and free of fluid leaks	Change in Habitat, Mortality Risk
Wash, refuel and service machinery in upland areas in such a way as to prevent any deleterious substances from entering a water body	Change in Habitat, Mortality Risk
Store fuel and other materials for the machinery in such a way as to prevent any deleterious substances from entering a water body	Change in Habitat, Mortality Risk
Establish a spill response plan with the following key mitigation measures: • report all spills as soon as possible when a deleterious substance enters a water body; • install containment measures around the spill; and, • collect and dispose of contaminated water or soil substrates using an emergency spill kit and other necessary spill response measures. Disposal will be at approved disposal facilities.	Change in Habitat, Mortality Risk
Allow for the regeneration of natural vegetation following the cessation of exploration in a work area	Change in Habitat
Clear vegetation for winter access roads down to the shrub level only (0.1 m in height)	Change in Habitat

Mitigation Measure	Potential Adverse Effect
Limit grubbing activities (i.e., removal of groundcover) to the drill hole location and the MBC sumps, and to larger stumps along winter access roads to improve snow packing and subsequent safe driving conditions	Change in Habitat
Develop and implement an erosion and sediment control plan to prevent the introduction of sediment into any water body during all work, undertakings and activities	Change in Habitat
Install erosion and sediment control measures, where appropriate, before beginning works, undertakings and activities	Change in Habitat
Maintain and inspect erosion and sediment control measures and structures regularly during all work, undertakings and activities	Change in Habitat
Keep the erosion and sediment control measures in place until all disturbed ground has been stabilized, then remove all erosion and sediment control materials (unless biodegradable)	Change in Habitat
Keep organic layers intact (i.e., limit grubbing and vegetation removal) wherever possible	Change in Habitat
Operate machinery on land in stable, dry areas	Change in Habitat
Monitor waterbodies regularly for signs of sediment entry during all phases of the works, undertakings and activities and take corrective action	Change in Habitat
Use biodegradable erosion and sediment control materials whenever possible	Change in Habitat
Post and enforce a speed limit of 50 km/hr on Project-related access roads	Mortality Risk
Implement a policy to minimize disturbance of wildlife on access roads, including providing wildlife with the right-of-way on roads, not using vehicles to entice wildlife to move off the road, and slowing or stopping until wildlife have cleared the road	Mortality Risk
Maintain appropriately sized gaps in roadside snowbanks to facilitate wildlife crossing and escape	Mortality Risk
Implement an on-site policy prohibiting workers from shooting, hunting, and fishing within the RSA	Mortality Risk
Prohibit workers from having personal firearms within the RSA	Mortality Risk
Investigate all Project-related wildlife mortality and correct the root cause(s) through adaptive management where possible	Mortality Risk
Increase the tortuosity of curves along seismic lines (to reduce sightlines and ease of travel)	Mortality Risk
Minimize seismic line widths and the total length of lines as much as possible (i.e., use as wide a spacing distance between lines as possible)	Mortality Risk
Create vegetation barriers along lines where they enter the high-value habitat, at least every 300 m within the habitat areas, to impede predator and human travel.	Mortality Risk

8.3.4 Effects Characterization

8.3.4.1 Approach

Residual effects on moose are characterized following those described in the Methods section (**Table 8-1**), including consideration of magnitude, likelihood, geographical extent, duration, frequency, timing,

reversibility, context, and confidence of the effect. The ratings and definitions for each residual effect characteristic are in **Table 8-1**and discussed explicitly in the relevant sections below.

8.3.4.2 Residual Change in Habitat Effects

The Project may affect the amount of suitable moose habitat in the RSA, resulting in a change in habitat. The assessment considers the direct loss of habitat and the indirect alteration (e.g., sensory disturbances, edge effects, perceived barriers) of habitat for moose across the range of the 10 footprint scenarios. Direct habitat loss was quantified by calculating the area of suitable moose habitat lost to clearing within the RSA. The alteration of suitable moose habitat is quantified by buffering Project components by 250 m and downgrading suitable habitat by one class within the buffer, where appropriate.

The Project may reduce the amount of suitable moose habitat within the RSA across the 10 footprint scenarios (**Table 8-17**). The change in suitable habitat under each scenario was compared with the amount of baseline suitable habitat for each rating category, resulting in a range of estimated changes in habitat for each rating (i.e., footprint scenarios – baseline). High-quality and Moderate-quality moose habitat may decrease by up to 0.9% and 7.5%, respectively, or up to 8.4% combined.

Table 8-17. Change in Moose Habitat in the Eagle Plains Regional Study Area Based on Assessing the 10 Footprint Scenarios

Baseline			Footprint Scenarios (n = 10)		Potential Change (n = 10)	
Habitat Rating	Area (ha)	Area (%)	Range (ha)	Range (%)	Range (ha)	Range (%)
High	16,944.4	7.1%	14,796 to 14,993	6.2 to 6.3	−1,951 to −2,148	−0.8 to −0.9
Moderate	145,394.1	60.9%	127,563 to 129,124	53.5 to 54.1	−16,270 to −17,832	−6.8 to −7.5
Low	74,514.5	31.2%	63,475 to 64,308	26.6 to 27.0	−10,207 to −11,040	−4.3 to −4.6
Nil	1,810.46	0.8%	30,278 to 32,492	12.7 to 13.6	28,468 to 30,682	11.9 to 12.9
Total	238,663.5	100.0	238,663.5	100.0		

A summary of the characterization of residual direct habitat effects on moose is provided in **Table 8-18.** The magnitude is expected to be low due to a <11% change in habitat from baseline conditions. The likelihood of a residual effect is deemed low as mitigation measures are expected to minimize, but not eliminate, any change in habitat. The geographic extent of changes in direct habitat loss is expected to occur only within the maximum disturbance area; however, habitat alteration may occur throughout the ZOI. The duration is expected to be medium-term, as the change in habitat will likely end in each work area following the completion of exploration and associated natural regeneration of each stage.

Sensory disturbances that may result in habitat alteration are expected to occur continuously throughout the life of the Project. Habitat loss will likely occur continuously as work areas change annually and clearing occurs in different areas of the seismic program. Habitat alteration is expected to end following the completion of exploration and associated reclamation, and the regeneration of natural vegetation is expected to reverse the loss of habitat. Therefore, the potential residual effect is reversible.

Table 8-18. Characterization of Potential Project Effects on Moose Habitat

Criterion		Rating	Rationale
Magnitude		Low	Vegetation clearing, including trees, is expected be required for access roads and seismic lines. As a result, Project-related activities are expected to result in a <11% change in habitat.
Likelihood		Certain	The probability of vegetation clearing causing direct habitat effects is certain.
Geographic Extent		Local	Changes in habitat alteration due to Project-related sensory disturbances are predicted to be limited to the ZOI. Direct habitat loss is predicted to be limited to the maximum disturbance area.
Duration, Frequency and Timing	Duration	Medium-term	A change in habitat is predicted to occur throughout the life of the Project.
	Frequency	Continuous	Habitat loss will likely occur once in each work stage; however, habitat alteration through sensory disturbances is expected to occur continuously.
	Timing	Year-round	The residual effect of that vegetation clearing is predicted to remain year-round until vegetation has regenerated.
Reversibility		Reversible	The alteration of habitat is expected to end following the completion of exploration and associated reclamation. The regeneration of natural vegetation is expected to reverse habitat loss.

8.3.4.2.1 Context and Confidence

The RSA is a Zone IV IMA in the North Yukon and Peel Watershed Planning Regions with which it overlaps. In these areas with diminished ecological and cultural values in a moderately sensitive biophysical setting, Zone IV IMAs allow for the highest level of development. Cumulative effect indicators are used in both plans if the current management and development are meeting the set goals and objectives. Two cumulative effects indicators included in the Plans are direct surface disturbance and linear density, with guidelines setting cautionary (0.75 km/km²) and critical (1.0 km/km²) indicator levels in both plans.

A network of linear features was previously created in parts of the RSA due to intermittent historical exploration activities. The Linear Feature Study (**Appendix 8-B**) determined the extent and characteristics of liner features in the RSA and addressed three objectives: (1) comprehensive mapping and classification of existing linear feature footprints within the RSA; (2) quantification of structural aspects (e.g., widths) and functional aspects (ease of travel and sightlines) of linear features; and (3) quantification of regeneration pathways and structural stages of linear features. That combined information supports assessing the Project's potential effects of linear features and refinement of mitigation measures for linear features to minimize possible effects. After accounting for natural features and regeneration, the adjusted linear feature density for the RSA was below the cautionary and critical indicator levels, at 0.52 km/km², in both regional land use plans.

The level of confidence in this prediction is Moderate (**Table 8-19**). The effects of habitat loss and alteration on moose are well-documented, and the efficacy of mitigation measures has been supported through

application on previous projects. However, there is some uncertainty in the specific context of those studies and the habitat conditions and harvest patterns at Eagle Plains.

Table 8-19. Characterization of Context and Confidence in the Residual Project Effects on Moose Habitat

Criterion	Rating	Rationale
Context	Highest Development	The Project occurs within the IMA Zone IV Management Unit, designated as the highest level of disturbance.
Confidence	Moderate	Mitigation measures are predicted to be effective at minimizing or eliminating the change in habitat; however, the uncertainty of the maximum disturbance footprint results in a Moderate Confidence of the residual effect prediction.

8.3.4.3 Residual Mortality Risk Effects

A summary of the characterization of residual indirect mortality effects on moose is provided in **Table 8-20.** The Magnitude is predicted to be low as mitigation measures are expected to minimize moose mortality risk to within natural variation. However, there is a possible likelihood of a change in mortality risk as while mitigation measures are expected to minimize, any change in mortality risk, they may not eliminate it. Project-related access roads and seismic lines may facilitate hunting access within the RSA, therefore the geographic extent is regional. The duration is expected to be medium-term, as the Frequency of the change in mortality risk is expected to occur continuously, but it will likely end following the completion of the Project. The timing of most work is planned to occur during the winter. Any changes in mortality risk are expected to end following the completion of exploration and associated reclamation, therefore, the potential residual effect is reversible.

Table 8-20. Characterization of Potential Project Effects on Moose Mortality Risk

Criterion		Rating	Rationale
Magnitude		Low	Project-related activities are expected to result in any change in mortality risk to remain within natural variation.
Likelihood		Possible	Mitigation measures are expected to minimize but not eliminate the potential for a change in mortality risk.
Geographic Extent		Regional	Changes in mortality risk are predicted to occur across the RSA due to potential of increased access.
Duration, Frequency and Timing	Duration	Medium-term	A change in mortality risk is predicted to occur throughout the entire exploration period of the Project.
	Frequency	Continuous	Changes to mortality risk are expected to occur continuously throughout the life of the Project.
	Timing	Year-round	Changes in mortality risk may occur year-round as Project access roads and seismic lines may be accessed year-round.
Reversibility		Reversible	Any change in mortality risk is expected to end following the completion of exploration and associated reclamation.

8.3.4.3.1 Context and Confidence

The RSA is a Zone IV IMA in the North Yukon and Peel Watershed Planning Regions with which it overlaps. In these areas with diminished ecological and cultural values in a moderately sensitive biophysical setting, Zone IV IMAs allow for the highest level of development.

The level of confidence in this prediction is High (**Table 8-21**). The effect of mortality risk on moose is known and the efficacy of mitigation measures has been supported through application on previous projects.

Table 8-21. Characterization of Context and Confidence in the Residual Project Effects on Moose Mortality Risk

Criterion	Rating	Rationale
Context	Highest Development	The Project occurs within the IMA Zone IV Management Unit, designated as the highest level of disturbance.
Confidence	High	Mitigation measures are predicted to be effective at minimizing or eliminating the change in mortality risk.

8.3.5 Significance

The Project is not expected to result in a change in moose habitat or a change in mortality risk that will alter the integrity of the moose population within the RSA to the point where it cannot sustain a regional population. The Project was designed to limit interactions with moose and moose habitat by avoiding suitable habitat to the extent practical. Standard mitigation measures have been applied to the Project, and these measures are known to be effective at minimizing residual adverse effects. Therefore, the residual effects are collectively predicted to be **not significan**t.

8.3.6 Cumulative Effects Assessment

8.3.6.1 Approach

Project-related residual effects with the potential to interact cumulatively with the residual effects of reasonably foreseeable projects and activities identified within or extending into the CESA on moose are:

- change in habitat; and,
- mortality risk.

The CESA delineates the spatial boundaries of the CEA for moose as described in **Section 3.1.6.1.1**. Projects and activities outside the CESA but with potential effects within this area, were also included in this assessment. Temporal boundaries for assessing cumulative effects encompass past, present, and reasonably foreseeable future activities spanning the Project's lifespan (**Section 1.3.1**).

8.3.6.2 Cumulative Change in Habitat Effect

The indicator used to characterize the change in habitat cumulative effect on moose was the total surface disturbance (area [km²] and percent [%]) from anthropogenic footprints (e.g., mineral exploration, oil and gas) disturbed by the footprints. Present conditions include a total area of 62.5 km² (0.6%) disturbed by past and present projects and activities within the CESA (**Table 8-22**). This is predicted to increase in the future by 1.2 km² (0.0%) following the inclusion of reasonably foreseeable projects and activities. The Project is expected to increase the amount of disturbed area over the existing conditions by a maximum of

69.5 km² (0.6%) within the CESA, resulting in a maximum disturbed area of 133.2 km² (1.2%) when combined with past, present, and reasonably foreseeable projects and activities.

The magnitude of cumulative change in habitat effects is expected to be low, as it is expected to be <1% increase over existing conditions. The likelihood of the cumulative effect is Probable due to mitigation measures minimizing but not eliminating the potential of the effect. Changes in habitat are expected to occur throughout the CESA due to projects and activities as part of the assessment; therefore, the cumulative effect is regional in geographic extent. The effect is predicted to end following the completion of projects and activities in an area, and as a result, it is medium-term in duration. The frequency of a change in habitat is expected to be continuous, as vegetation clearing will likely occur occasionally, but its effects on habitat are predicted to be continuous until vegetation regenerates. The effect of a change in habitat due to projects and activities within the CESA is predicted to have year-round timing. Over time, it is predicted that the regeneration of the affected habitat will likely occur after the end of the projects and activities considered in the assessment and will likely reverse the cumulative effect. A summary of the characteristics of the cumulative effects of change in habitat is provided in **Table 8-23**.

Table 8-22. Cumulative Change in Habitat Effects from Existing and Project-Related Disturbances on Moose

Cumulative Effect Indicator	Scenario	Cumulative Effects Study Area
Total Surface Disturbance (Footprints)	Present	62.5 km² (0.6%)
	Project	69.1–69.5 km² (0.6%)
	Future	1.2 km² (0.0%)
	Total Cumulative Effect	132.8–133.2 km² (1.2%)

Table 8-23. Characterization of Cumulative Change in Habitat Effects on Moose

Criterion		Rating	Rationale
Magnitude		Low	The change in habitat across the CESA is predicted to be <1% over existing conditions.
Likelihood		Probable	Mitigation measures are expected to minimize but not eliminate the potential for a change in habitat.
Geographic Extent		Regional	Change in habitat quality is expected to occur across the CESA due to the location of the projects and activities.
Duration, Frequency and Timing	Duration	Medium-term	The effect is expected to end following the ending of projects and activities in an area.
	Frequency	Continuous	Vegetation clearing required for projects and activities may occur occasionally, but the cumulative effect on moose will continue until vegetation regenerates.

Criterion		Rating	Rationale
	Timing	Year-round	The effect is expected to occur year-round due to changes in habitat remaining until vegetation regeneration.
Reversibility		Reversible	The regeneration of the affected habitat is expected to be reversible over time.

8.3.6.2.1 Context and Confidence

The assessment of the cumulative change in habitat effects on moose considered the context of Regional Land Use Planning and the confidence in accurately quantifying and predicting those effects (**Table 8-24**). The characterization of effects is consistent with the Land Use Plans' objectives, and there is relatively high confidence that effects were accurately captured in the assessment. Although it is possible that some anthropogenic features were not fully accounted for in the total disturbance calculation, there is a high degree of confidence that most disturbances were included. Therefore, the confidence in this CEA is high.

Table 8-24. Characterization of Context and Confidence in the Assessment of Cumulative Change in Habitat Effects on Moose

Criterion	Rating	Rationale
Context	Conforms to Regional Land Use Plans	Land Management Unit IV zones of the North Yukon and Peel Regional Land Use Plans are areas zoned for the highest level of development. The Project activities are consistent with the integrated resource management objectives of the LUPs.
Confidence	High	There is high confidence in characterizing the cumulative effect and its persistence. A precautionary approach was taken to quantify the change in habitat effect.

8.3.6.3 Cumulative Mortality Risk Effect

Cumulative mortality risk effects result from linear features across the landscape, with higher linear feature densities (km/km²) supporting facilitated moose predation by wolves and human hunting. Therefore, linear feature density was used to assess cumulative mortality risk effects. Linear feature density was calculated as the total length of linear features divided by the size of the CESA.

A summary of the cumulative effect indicator for mortality risk effects is provided in **Table 8-25**. Due to the Project, linear feature density is expected to increase by up to 2.23 km/km² in the CESA relative to existing conditions. The increase in linear feature density occurs due to the Project contributing approximately 83.56 km of additional linear features.

The magnitude of cumulative mortality risk effects is expected to be high because the overall linear feature density is predicted to increase by >35% from baseline values. The likelihood of the cumulative effect is probable due to mitigation measures minimizing but not eliminating the effect. The Geographic Extent of the cumulative effect is expected to be regional, as effects may occur throughout the CESA due to projects and activities considered in this assessment. The duration of the effect is expected to occur over the medium-term as risk is expected to end following the activities in an area. The frequency of the cumulative effect is expected to be continuous as conditions that facilitate predator and human hunter access along linear features may occur all the time. The Timing of the effect is expected to occur year-round as projects

and activities within the CESA are expected to result in mortality risk throughout the year. Over time, it is predicted that mortality risk will likely end following the completion of reasonably foreseeable projects and activities in an area and will likely reverse the cumulative effect. A summary of the characterization of the cumulative effects on mortality risk is provided in **Table 8-26**.

Table 8-25. Cumulative Mortality Risk Effects from Existing and Project-Related Disturbances on Moose

Cumulative Effect Indicator	Condition[1]	Cumulative Effects Study Area
Linear Feature Density	Existing	0.78 km/km² (8,716.29 km)
	Future	3.01–3.01 km/km² (33,830.6–33,890.5 km)
	Net Effect	2.23–2.23 km/km² (25,177.10–25,237.02 km)

Net effect refers to the increase in the cumulative effect indicator from existing to future conditions due to the Project.

Table 8-26. Characterization of Cumulative Mortality Risk Effects on Moose

Criterion		Rating	Rationale
Magnitude		High	The increase in linear feature density due to the Project is expected to be >35%.
Likelihood		Probable	Mitigation measures are expected to minimize but not eliminate mortality risk. The Project contributes to the increased linear feature density that could result in facilitated hunting and predation.
Geographic Extent		Regional	Change in habitat quality is expected to occur across the CESA due to the location of the projects and activities.
Duration, Frequency and Timing	Duration	Medium-term	A change in mortality risk is predicted to end following the completion of projects and activities in an area.
	Frequency	Continuous	Conditions that could lead to mortality risk are anticipated to occur continuously.
	Timing	Year-round	Within a given year, conditions that could lead to mortality risk are mostly limited to fall and winter. However, those effects may continue throughout the year.
Reversibility		Reversible	The mortality risk is expected to be reversible following the cessation of projects and activities.

8.3.6.3.1 Context and Confidence

The assessment of the cumulative mortality risk effects on moose considered the context of Regional Land Use Planning and the confidence in accurately quantifying and predicting those effects (**Table 8-27**). The characterization of effects is consistent with the Land Use Plans' objectives, and there is relatively high confidence that effects were accurately captured in the assessment. It is possible that some anthropogenic features were not included in the linear feature density calculation, there is a high degree of confidence that most disturbances were included. Therefore, the confidence in this CEA is high.

Table 8-27. Characterization of Context and Confidence in the Assessment of Cumulative Mortality Risk Effects on Moose

Criterion	Rating	Rationale
Context	Conforms to Regional Land Use Plans	Land Management Unit IV zones of the North Yukon and Peel Regional Land Use Plans are areas zoned for the highest level of development. The Project activities are consistent with the integrated resource management objectives of the LUPs.
Confidence	High	There is high confidence in characterizing the cumulative effect and its persistence. A precautionary approach was taken to quantify the change in habitat effect.

8.4 BIRDS

A total of 353 bird species may occur in the Yukon, most of which are protected under the federal *Migratory Birds Convention Act* (*MBCA*) and the associated *Migratory Birds Regulations,* the *Yukon Wildlife Act, or the Species at Risk Act* (*SARA*) (Government of Canada 2002, 2018, Government of Yukon 2002). Baseline studies identified nine bird species of conservation concern (birds hereafter; species listed under *SARA* or the *Yukon Wildlife Act*) that could occur in the RSA and those species are the focus of this assessment (**Table 8-28**). Five of those species have been detected in the RSA and the other four are likely to occur, although it is uncertain if they breed regularly within the RSA.

Table 8-28. Bird Species of Conservation Concern that Could Occur in the Eagle Plains Regional Study Area During the Breeding Season

Species Common Name	COSEWIC[4]	SARA[5]	BCR 4 Priority[6]	Yukon Wildlife Act	RSA Count	NABBS Count (2014–2018)[7]
Horned Grebe[1]	SC (Apr 2009)	1 – SC	R – stewardship N/C – concern	No	0	0
Red-necked Phalarope	SC (Nov 2014)	1 – SC	N/C – concern	No	15	0
Peregrine Falcon[2]	NAR (Nov 2017)	1 – SC	R – stewardship N/C – concern	Yes	0	0
Gyrfalcon[2]	NAR (Apr 1987)	–	–	Yes	0	0
Short-eared Owl[1]	T (May 2021)	1 – SC	N/C – concern	No	0	4
Common Nighthawk[3]	SC (Apr 2018)	1 – T	N/C – concern	No	1	0
Olive-sided Flycatcher	SC (Apr 2018)	1 – T	R – stewardship R/N/C – concern	No	6	1
Bank Swallow[1]	T (May 2013)	1 – T	–	No	0	0

Species Common Name	COSEWIC[4]	SARA[5]	BCR 4 Priority[6]	Yukon Wildlife Act	RSA Count	NABBS Count (2014–2018)[7]
Rusty Blackbird	SC (Apr 2017)	1 – SC	R – stewardship R/N/C – concern	No	19	1
Totals					**41**	**6**

[1] Species that are 'Likely' to occur in the Eagle Plains Project RSA.
[2] Cliff nesting raptors that are 'Likely' to occur in the broader region, but do not have suitable habitat in the Eagle Plains Project RSA.
[3] A species that may occur in the Project RSA but is at its range limits. One occurrence was observed, but status remains uncertain.
[4] Most recent COSEWIC assessments; E = Endangered, NAR = Not at Risk, SC = Special Concern, T = Threatened.
[5] SARA statuses from the latest amended list in August 2019; Schedule 1 codes equivalent to COSEWIC.
[6] Priorities, concerns, and stewardships from BCR 4 2013 report; C = Continental, N = National, R = Regional.
[7] North American Breeding Bird Survey Counts (from routes that intersect the RSA)

Horned Grebe — Horned grebe is a small waterbird species that nests in small to medium (0.05 – 10 ha) ponds and wetlands with considerable amounts of emergent vegetation (Stedman 2020). It breeds and winters across the northern hemisphere, and in North America, it breeds principally from Alaska to western Ontario and winters on the east and west coasts of the continent (Stedman 2020). It breeds across the Yukon in suitable habitat and may occur from April through November (Cornell Lab of Ornithology 2023). No horned grebes were detected during the wildlife baseline surveys.

The horned grebe is listed as Special Concern under COSEWIC and *SARA* (B.C. Conservation Data Centre 2023). Initially, the horned grebe population was thought to have declined by 45% since the mid-1960s; however, a recent analysis has found a relatively stable continental population since the 1970s, but several regional populations may have declined (Canada 2021). Habitat loss and degradation are considered the primary threats, although pollution and mortality from fishing are also considered threats (Canada 2021).

Red-Necked Phalarope — The red-necked phalarope is a shorebird that nests primarily on or near freshwater wetlands, ponds, streams, and winters primarily on the open ocean and occasionally on evaporation ponds (Rubega et al. 2020). It has a circumpolar breeding distribution across the arctic or subarctic. In North America, it breeds from Alaska to Labrador, and it winters in tropical oceans, notably off the west coast of South America, the Arabian Sea, and Indonesia (Rubega et al. 2020). It breeds across the Yukon and generally occurs from May to September (Cornell Lab of Ornithology 2023). It was detected several times during the wildlife baseline surveys on open water.

Red-necked Phalarope is designated as Special Concern by both COSEWIC and *SARA* (B.C. Conservation Data Centre 2023). The current population size or trends are uncertain due to the remote nature of its breeding and wintering habitats, but large population declines have been noted in the Bay of Fundy (COSEWIC 2014). Threats to this species are relatively unknown, but declines in prey species have been implicated in the Bay of Fundy declines, and pollutants (e.g., pesticides, heavy metals) may affect reproductive success and health (COSEWIC 2014).

Peregrine Falcon — Peregrine falcons often nest on cliff ledges or crevices but may sometimes nest on buildings, river banks, raptor or raven nests, and tree hollows near generally open foraging habitat (White

et al. 2020). It has a widespread range and breeds on all continents, except Antarctica, and across North America, although it is reoccupying much of its historic range in the east and south (White et al. 2020). It breeds across most of the Yukon and generally occurs from April to October (Cornell Lab of Ornithology 2023). No peregrine falcons were detected during the wildlife baseline surveys, and no suitable nesting habitat is known within the RSA.

The peregrine falcon is designated as Not at Risk by both COSEWIC and *SARA*, but is included in the *Yukon Wildlife Act* as "Specially Protected Wildlife" (Government of Yukon 2012, B.C. Conservation Data Centre 2023). Populations across North America declined dramatically in the mid-20th century due to widespread reproductive failure from dichlorodiphenyltrichloroethane (DDT), an insecticide used in agriculture. Subsequently, populations recovered after banning DDT and a widespread reintroduction program (COSEWIC 2017a). The main threat continues to be pollution (e.g., pesticides, heavy metals, flame retardants) that can negatively affect their health and cause reproductive failure (COSEWIC 2017a).

Gyrfalcon — The gyrfalcon nests on rocky cliffs above the treeline in mountainous areas or the arctic tundra, and occurs in relatively flat, open areas during the rest of the year (Booms et al. 2020). The gyrfalcon is circumpolar in distribution, and in North America, breeds across northern Canada and Alaska and winters south to the northern United States (US) (Booms et al. 2020). It nests in mountainous areas across the Yukon and may occur year-round (Booms et al. 2020, Cornell Lab of Ornithology 2023). No gyrfalcons were detected during the wildlife baseline surveys, and no suitable nesting habitat is known within the RSA.

Gyrfalcon is designated as Not at Risk by both COSEWIC and *SARA*, but is included in the *Yukon Wildlife Act* as "Specially Protected Wildlife" (Government of Yukon 2012, B.C. Conservation Data Centre 2023). Most known threats to gyrfalcons (e.g., egg collecting, poaching, habitat loss, pesticides) do not appear to threaten North American populations, where most populations are stable (Booms et al. 2020).

Short-Eared Owl — The short-eared owl breeds and forages in open habitats such as grasslands, tundra and wetlands that are greater than 50 ha in area. It is one of the most widely distributed owl species, and breeds or is resident across most of Canada and the northern US. It occurs in winter across the southern US and northern Mexico (Wiggins et al. 2020). It is found across the Yukon as a breeding species and occurs from March to December (Cornell Lab of Ornithology 2023). Short-eared owls were not detected during baseline wildlife surveys, but several were detected during the North American Breeding Bird Surveys from 2014-2018.

The short-eared owl is designated as Threatened by COSEWIC and Special Concern by *SARA* (B.C. Conservation Data Centre 2023). Population declines of 79% between 1970 and 2019 and 27% between 2007 and 2019 were cited as rationales for their conservation listing (COSEWIC 2021). The main threat is habitat loss from agricultural conversion and intensification, climate change, urbanization, and invasive plants (COSEWIC 2021).

Common Nighthawk — Common Nighthawk nest and forage in open and partially open areas such as forest openings, burned areas, bogs, rocky or sandy habitats or disturbed areas (Brigham et al. 2020). The breeding range extends from Central America to northern Canada, wintering occurs primarily in South America, and it also occurs year-round in the Caribbean (Brigham et al. 2020). In the Yukon, it occurs only as a breeding species from June to September, primarily in the southern half of the territory, and sporadic records up to the north coast (Cornell Lab of Ornithology 2023). One common nighthawk was observed incidentally during baseline wildlife surveys in a riparian area.

The species is designated as Special Concern by COSEWIC and Threatened by *SARA* (B.C. Conservation Data Centre 2023). The primary rationale for listing was a 68% population decline between 1970 and 2015, and a 12% decline between 2005 and 2015 in southern Canada, although trends are hard to determine for this species (COSEWIC 2018a). Threats include reductions of flying insect feeding resources from pesticides, collisions with vehicles, and habitat loss and degradation (COSEWIC 2018a).

Olive-Sided Flycatcher — The olive-sided flycatcher nests in mature to old-growth, open coniferous or mixed wood forests, along the edges of these forests, riparian areas, burns, and clearcuts (Altman and Sallabanks 2020). Its breeding range is across the boreal forest and coniferous forests across western North America and wintering from Mexico through South America (Altman and Sallabanks 2020). It breeds across most of the Yukon and is found in the territory from May through September (Cornell Lab of Ornithology 2023). Baseline surveys detected individuals in riparian areas and deciduous/mixed shrub habitats.

The species is designated as Special Concern by COSEWIC and Threatened by *SARA* (B.C. Conservation Data Centre 2023). Population declines of 72% since 1970 and 19% between 2006 and 2016 were cited as reasons for their conservation listing (COSEWIC 2018b). Threats include habitat loss on breeding and wintering grounds, fire suppression, and prey reductions from pesticide use (COSEWIC 2018b).

Bank Swallow — Bank Swallow excavate nests in sand-silt substrates along vertical banks in natural (e.g., riverbanks, lake bluffs) and human-created (e.g., gravel pits, soil piles, road cuts) areas, often near open habitats used for foraging (Garrison and Turner 2020). The species has a near global distribution, breeds across much of Canada and the northern US, and winters from Mexico through South America (Garrison and Turner 2020). It occurs throughout the Yukon as a breeding species and may occur from May through September (Cornell Lab of Ornithology 2023). It was not detected during baseline surveys, likely due to its more specialized habitat requirements.

Bank Swallow is designated as Threatened by both COSEWIC and *SARA* (B.C. Conservation Data Centre 2023). Its listing results from population declines of up to 98% between 1970 and 2011 in Canada, with a potential decline of 31% between 2001 and 2011 (COSEWIC 2013). Principal threats include habitat loss (e.g., poor erosion control, dam building, aggregate mining), loss of foraging habitat (i.e., open areas near nest sites), prey reductions from pesticide use, and vehicle collisions (COSEWIC 2013).

Rusty Blackbird — Rusty Blackbird is a riparian-associated species that nests and forages in various open, shrub, and forest habitats adjacent to lakes, ponds, slow-flowing streams, and wetlands (Avery 2020). The breeding range is across the boreal forest, and the winter range is in the southeastern US and Canada (Avery 2020). In the Yukon, it occurs only as a breeding species and may occur from late April through October (Cornell Lab of Ornithology 2023). Baseline surveys detected the species at several riparian and herb sites across the RSA.

Rusty Blackbird is designated as Special Concern by both COSEWIC and *SARA* (B.C. Conservation Data Centre 2023). The primary rationale for its conservation listing are population declines of 85–90% since 1970 and is of special importance for Canadian conservation because 87% of the breeding population occurs in Canada (COSEWIC 2017b). The primary reasons for the decline are associated with the wintering range, including habitat loss and degradation, large-scale blackbird control programs, and agricultural pesticides (COSEWIC 2017b). Although habitat loss (i.e., wetland conversion) on the breeding grounds has also played a minor role (COSEWIC 2017b). Threats to the species in the Yukon are low; human

activities in the Yukon generally have limited interactions with Rusty Blackbirds and their habitats (COSEWIC 2017b).

8.4.1 Assessment Indicators and Parameters

The potential effects on birds include a change in habitat and mortality risk that may result from interactions with the Project. The Project can affect bird habitat by clearing vegetation and mortality risk during the brief overlap with seismic testing. The effect of change in habitat and mortality risk were assessed qualitatively.

8.4.2 Project Interactions and Potential Effects

This subsection characterizes interactions between the Project and birds and describes the potential adverse effects.

8.4.2.1 Interactions Table

Interactions between the birds and Project-related activities and components may result in a change in habitat (i.e., the direct loss of habitat and the indirect alteration of adjacent habitat) and mortality risk (for the brief times when Project activities might overlap with birds present in the RSA). However, interactions resulting in a change in mortality risk are predicted to be minor, not resulting in an immeasurable effect, and will not be carried forward into the residual effect characterization. Consequently, the potential effect of change in habitat is carried forward into the assessment of the summary evaluation in this section. **Table 8-29** summarizes the potential interactions, and those interactions and effects are discussed in more detail below.

Table 8-29. Expected Interactions Between Bird Change in Habitat and Mortality Risk and the Eagle Plains Exploration Project

Project Component / Activity	Change in Habitat	Change in Mortality Risk
Engagement	0	0
Seismic Exploration	2	1
Drilling Exploration	2	0
Extended Flow Testing (EFT)	1	0
Well Maintenance (Workovers)	1	0
Access Roads	2	1
Mix Bury Cover (MBC) Construction and Operation	2	1
Central Processing Facility (CPF)	2	0
Airstrip	2	1
Water Withdrawal	1	0
Transportation	2	1
Camp	2	1
Reclamation and Closure	1	1

Notes:
0 = no interaction
1 = minor interaction with birds possible, but small immeasurable effect (e.g., possible slight behavioural response, no vegetation effects, no measurable effect on water quality). Designates a summary of effects that are addressed in the effects assessment as a discussion. This rating does not lead into residual effects characterization.
2 = substantial interaction with birds, designates a more detailed assessment of potential effects. Carry forward into residual effects characterization.

8.4.2.2 Change in Habitat

Direct loss of suitable bird habitat may occur within the Project footprint because of vegetation clearing required to construct Project components (e.g., seismic lines, well pads, camp, and winter access roads). Each work area will require vegetation clearing once at the start of activity within the specific work area. The assessment of the effect, change in habitat, encompasses the entire operational period of the Project (i.e., 10 years).

Direct habitat loss and the alteration of habitat may result in the fragmentation of suitable habitat. Habitat fragmentation can result in a loss or reduction in habitat connectivity and generate isolated patches of suitable habitat below the minimum patch size required to support a species (Andrén 1994, Villard et al. 1999, Vance et al. 2003). When available suitable habitat is below a minimum patch size threshold, a reduction in occupancy may occur despite the continued presence of suitable habitat on the landscape (Robbins et al. 1989, Askins 1994, Butcher et al. 2010).

Sensory disturbances associated with human activity, construction activity, and anthropogenic features (e.g., camp, access roads) can affect bird behaviour and alter habitat use and suitability. In forested landscapes, the effect distances in response to industrial activities and roads can vary considerably, with most effects ranging from 50 – 300 m, but a few larger effect distances (i.e., up to 365 m or more) have been reported (Reijnen et al. 1997, Hanowski et al. 1999, Habib et al. 2007, Bayne et al. 2008, Francis et al. 2009). The larger effect distances were typically associated with a higher level of disturbance than anticipated for the Project.

8.4.2.3 Change in Mortality Risk

The primary sources of direct mortality risk from Project-related activities are vehicle collisions and nest destruction or disturbance. The primary source of indirect mortality is increased mortality risk from nest predators. If any changes in bird mortality risk occur, they are expected to be limited to active work areas and the surrounding ZOI during seismic testing. However, most Project activities will occur during the winter when most bird species are not present in the RSA, and none are breeding (Cornell Lab of Ornithology 2023). Mitigation measures are also expected to limit interactions between birds and potential sources of mortality, minimizing the potential effect of change in mortality risk.

Most Project activities will occur during the winter; however, seismic recording may stretch into the summer and will require vehicle traffic to transport materials, equipment, and workers. Bird mortality from vehicle collisions in Canada was estimated to be 13.8 million birds and 89 to 340 million birds in the US, with an average of 3,462 birds/km in Canada and 36 birds/km in the US (Bishop and Brogan 2013, Loss et al. 2014). In Canada, coniferous forests had some of the lowest vehicle mortality rates (0.34 – 1.5 birds/km) in contrast with wetlands 164 birds/km) and most mortality occurs during the breeding and fledging periods (Bishop and Brogan 2013). In addition, traffic volume is an important factor in the occurrence of vehicle

mortality of birds, and most estimates are for paved roads with higher levels of traffic than gravel roads (Bishop and Brogan 2013).

Seismic recording work will also require the placement of charges along seismic lines. Mortality risk associated with the work could destroy nests (i.e., incidental walking or running over a nest resulting in the death of young or eggs) or disturbance to nesting birds (i.e., disturbance to nesting birds that leads to the abandonment or predation of a nest and results in the death of young or eggs) (Baudains and Lloyd 2007, Calvert et al. 2013). However, compared to other potential sources of mortality, the upper limit of mortality estimate from seismic recording (16,438 nests nationwide) is relatively low (Calvert et al. 2013).

Nest predators of songbirds (e.g., Canada jay [*Perisoreus canadensis*], red squirrel [*Tamiasciurus hudsonicus*]) may occur at higher abundances or prefer foraging along forest edges (King et al. 1998, Ibarzabal and Desrochers 2004). Studies have linked this with an increased risk of nest mortality for songbirds (Manolis et al. 2002, Ibarzabal and Desrochers 2004). Project construction will require the clearing of vegetation that may increase the amount of forest edge habitat; however, mitigation measures are expected to minimize the amount of clearing required and the potential effect of change in mortality risk.

8.4.3 Mitigation Measures

Mitigation measures to avoid and minimize changes to bird habitat and mortality risk will be implemented as part of the Project design and during Project activities. Some mitigation measures may broadly apply to other VESECs, whereas others may be only to birds. Measures may also be applicable to both potential effects or each individually.

Mitigation measures to address both potential effects encompass several strategies. The most important mitigation measure to avoid potential effects is restricting most work activities to the winter. No birds will be breeding when most work activities occur, and few will be present within the RSA. Seismic recording may occur during the summer, resulting in the potential for mortality risk; however, mitigation measures are anticipated to minimize the residual effect to a minor interaction. In addition, Project activities and components will require the clearing of bird habitat, which may result in a change in bird habitat. To avoid and minimize changes to bird habitat, the spatial extent of the Project will be reduced to the smallest footprint required, and equipment and directed lighting will be limited to the Project footprint through the clear delineation of Project boundaries. For on-site personnel, mandatory environmental orientation, the use of wildlife reporting cards, and prohibitions on pets, firearms, hunting, and harassment will be enforced. Additionally, comprehensive plans addressing harmful substances, waste management, and traffic are expected to minimize and avoid further changes to habitat and mortality risks.

The environmental constraints mapping (**Section 3.3.2**) incorporates avoiding the placement of Project components (e.g., seismic lines, access roads) in potential bird habitat, to the extent possible, and avoiding work in riparian habitats and wetlands. Avoiding riparian habitats and wetlands is anticipated to eliminate interactions with horned grebe and red-necked phalarope. To minimize changes to bird habitat and facilitate natural regeneration, vegetation clearing will be limited to a height of 0.1 m high, except at the drill hole location and MBC sumps where grubbing will occur, and to larger stumps along winter access roads to improve snow packing and subsequent safe driving conditions. Pre-clearance wildlife feature surveys will be conducted before vegetation removal or grubbing to identify active bird nests, and if located, no-work buffers will be created and maintained to minimize disturbance. A plan will be developed to address

potential erosion and sediment control concerns that are also anticipated to avoid and minimize changes to bird habitat.

All mitigation measures applicable to birds, organized by potential effect, are summarized in **Table 8-30**.

Table 8-30. Mitigation Measures Relevant to Birds and the Eagle Plains Exploration Project

Mitigation Measure	Potential Adverse Effect
Minimize the spatial extent of new components by using existing infrastructure (e.g., access roads, winter trails, seismic lines) wherever feasible	Change in Habitat, Mortality Risk
Minimize seismic line widths and the total length of lines as much as possible (i.e., use as wide a spacing distance between lines as possible)	Change in Habitat, Mortality Risk
Delineate the Project footprint boundaries and restrict equipment use to within the defined areas	Change in Habitat, Mortality Risk
Use winter access roads for Project-related activities to the extent practicable	Change in Habitat, Mortality Risk
Use buses or vans for transporting employees, visitors, and contractors as much as practical to reduce Project-related traffic	Change in Habitat, Mortality Risk
Directed lighting or light shielding at well sites and camps, rather than broad lighting, to focus lighting toward the ground in work areas	Change in Habitat, Mortality Risk
Prohibit workers from having domestic pets within the RSA	Change in Habitat, Mortality Risk
Prohibit workers, visitors, or contractors from feeding or harassing wildlife within the maximum disturbance footprint	Change in Habitat, Mortality Risk
Implement a wildlife orientation for all site personnel. The orientation will include information about potential Project effects on water, fish, vegetation and wildlife, potential wildlife crossings, wildlife mitigation measures, and waste management policies that limit human-wildlife interactions	Change in Habitat, Mortality Risk
Require workers to report all bird observations through a logbook or information directly passed to the on-site environmental lead	Change in Habitat, Mortality Risk
Develop a plan to prevent deleterious substances from entering a water body	Change in Habitat, Mortality Risk
Maintain all machinery on site in a clean condition and free of fluid leaks	Change in Habitat, Mortality Risk
Wash, refuel and service machinery in upland areas in such a way as to prevent any deleterious substances from entering a water body	Change in Habitat, Mortality Risk
Store fuel and other materials for the machinery in such a way as to prevent any deleterious substances from entering a water body	Change in Habitat, Mortality Risk
Establish a spill response plan with the following key mitigation measures: • report all spills as soon as possible when a deleterious substance enters a water body; • install containment measures around the spill; and, • collect and dispose of contaminated water or soil substrates using an emergency spill kit and other necessary spill response measures. Disposal will be at approved disposal facilities.	Change in Habitat, Mortality Risk

Mitigation Measure	Potential Adverse Effect
Allow for the regeneration of natural vegetation following the cessation of exploration in a work area	Change in Habitat
Clear vegetation for winter access roads down to the shrub level only (0.1 m in height)	Change in Habitat
Limit grubbing activities (i.e., removal of groundcover) to the drill hole location and the MBC sumps, and to larger stumps along winter access roads to improve snow packing and subsequent safe driving conditions	Change in Habitat
Develop and implement an erosion and sediment control plan to prevent the introduction of sediment into any water body during all phases of the works, undertakings and activities	Change in Habitat
Install erosion and sediment control measures, where appropriate, before beginning works, undertakings and activities	Change in Habitat
Maintain and inspect erosion and sediment control measures and structures regularly during all phases of the works, undertakings and activities	Change in Habitat
Keep the erosion and sediment control measures in place until all disturbed ground has been stabilized, then remove all erosion and sediment control materials (unless biodegradable)	Change in Habitat
Keep organic layers intact (i.e., limit grubbing and vegetation removal) wherever possible	Change in Habitat
Operate machinery on land in stable, dry areas	Change in Habitat
Monitor waterbodies regularly for signs of sediment entry during all phases of the works, undertakings and activities and take corrective action	Change in Habitat
Use biodegradable erosion and sediment control materials whenever possible	Change in Habitat
Post and enforce a speed limit of 50 km/hr on Project-related access roads	Mortality Risk
Implement a policy to minimize disturbance of wildlife on access roads, including providing wildlife with the right-of-way on roads, not using vehicles to entice wildlife to move off the road, and slowing or stopping until wildlife have cleared the road	Mortality Risk
Implement an on-site policy prohibiting workers from shooting, hunting, and fishing within the RSA	Mortality Risk
Prohibit workers from having personal firearms within the RSA	Mortality Risk
Investigate all Project-related wildlife mortality and correct the root cause(s) through adaptive management where possible	Mortality Risk

8.4.4 Effects Characterization

8.4.4.1 Approach

Residual effects on birds follow those described in the Methods Section (**Table 8-1**), including consideration of magnitude, likelihood, geographical extent, duration, frequency, timing, reversibility, context, and confidence of the effect. The ratings and definitions for each residual effect characteristic are in **Table 8-1**and discussed explicitly in the relevant sections below.

8.4.4.2 Residual Change in Habitat Effects

Project activities will potentially alter a maximum area of <3% of vegetation and ecosystems within the RSA and are of low magnitude. Mitigation measures are anticipated to minimize the likelihood of a residual effect but not eliminate it, resulting in its possible occurrence. The geographic extent is local because habitat loss will occur within the Project footprint; however, habitat alteration due to sensory disturbances may occur within the ZOI, resulting in a local extent. The duration will be medium-term, as suitable habitat will regenerate through the life of the Project, and effects from sensory disturbances are expected to end following the completion of the Project. The frequency of changes in habitat is continuous, as work areas change annually and clearing occurs in different areas of the seismic program. The residual effect from habitat loss and alteration is expected to occur year-round until the Project is complete. Habitat alteration will end following the completion of exploration and associated reclamation, and the regeneration of natural vegetation will reverse the loss of habitat. Therefore, the potential residual effect is reversible.

Table 8-31. Characterization of Potential Project Effects on Bird Habitat

Criterion		Rating	Rationale
Magnitude		Low	The maximum potential change in the relative availability of vegetation and ecosystems within the RSA is <3%. Vegetation clearing, including trees, is expected to be required for access roads and seismic lines.
Likelihood		Possible	Mitigation measures are expected to minimize but not eliminate the potential for change in habitat.
Geographic Extent		Local	Changes in habitat alteration due to Project-related sensory disturbances are predicted to be limited to the ZOI. Direct habitat loss is predicted to be limited to the maximum disturbance footprint.
Duration, Frequency and Timing	Duration	Medium-term	A change in habitat is predicted to occur throughout the entire exploration period of the Project.
	Frequency	Continuous	Habitat loss will occur once in each work stage; however, habitat alteration through sensory disturbances are expected to occur continuously.
	Timing	Year-round	The residual effect of that vegetation clearing is predicted to remain year-round until vegetation has regenerated.
Reversibility		Reversible	The habitat alteration is expected to end after the completion of exploration and associated reclamation. The regeneration of natural vegetation is expected to reverse habitat loss.

8.4.4.2.1 Context and Confidence

The RSA overlaps with a Zone IV IMA in the North Yukon and Peel Watershed Planning Regions. This zone is an area of diminished ecological and cultural values in a moderately sensitive biophysical setting and allows for the highest level of development. Cumulative effect indicators are used in both plans if the current management and development are meeting the set goals and objectives. Two cumulative effects indicators included in the Plans are direct surface disturbance and linear density, with guidelines setting cautionary (0.75 km/km²) and critical (1.0 km/km²) indicator levels in both plans.

A network of linear features was previously created in parts of the RSA due to intermittent historical exploration activities. The Linear Feature Study (**Appendix 8-B**) determined the extent and characteristics of liner features in the RSA and addressed three objectives: (1) comprehensive mapping and classification of existing linear feature footprints within the RSA; (2) quantification of structural aspects (e.g., widths) and functional aspects (ease of travel and sightlines) of linear features; and (3) quantification of regeneration pathways and structural stages of linear features. That combined information supports assessing the Project's potential effects of linear features and refinement of mitigation measures for linear features to minimize possible effects. After accounting for natural features and regeneration, the adjusted linear feature density for the RSA was below the cautionary and critical indicator levels, at 0.52 km/km², in both regional land use plans.

The level of confidence in this prediction is Moderate (**Table 8-32**). The direct effects of both habitat loss and alteration on birds are well-documented, and the efficacy of mitigation measures has been supported through application in previous projects. However, there is some uncertainty in the specific context of those studies and the habitat conditions at Eagle Plains.

Table 8-32. Characterization of Context and Confidence in the Residual Project Effects on Bird Habitat

Criterion	Rating	Rationale
Context	Highest Development	The Project occurs within the IMA Zone IV Management Unit, designated as the highest level of disturbance.
Confidence	Moderate	Mitigation measures are expected to effectively avoid and minimize the changes in bird habitat; however, the uncertainty of the Project footprint results in Moderate Confidence in the residual effect prediction.

8.4.5 Significance

The Project is not expected to result in a change in bird habitat that will alter its integrity within the RSA to the point where it cannot sustain the regional populations of birds. The Project was designed to limit interactions with birds and bird habitat by avoiding suitable habitat to the extent practical. Standard mitigation measures, known to be effective at minimizing residual adverse effects, have been applied to the Project. Therefore, the residual effect is **not significant**.

8.4.6 Cumulative Effects Assessment

8.4.6.1 Approach

Project-related residual effects with the potential to interact cumulatively with the residual effects of projects and activities identified within or extending into the CESA was a change in habitat.

The spatial boundaries of the CEA on birds are delineated by the CESA as described in **Section 3.1.6.1.1**. Projects and activities outside the CESA but with potential effects within this area were also included in this assessment. Temporal boundaries for assessing cumulative effects encompass past, present, and reasonably foreseeable future activities spanning the Project's lifespan (**Section 1.3.1**).

8.4.6.2 Cumulative Change in Habitat Effect

The indicator used to characterize the change in habitat cumulative effect on moose was the total surface disturbance (area [km²] and percent [%]) from anthropogenic footprints (e.g., mineral exploration, oil and gas) disturbed by the footprints. Present conditions include a total area of 62.5 km² (0.6%) disturbed by past and present projects and activities within the CESA (**Table 8-33**). This is predicted to increase by 1.2 km² (0.0%) following the inclusion of reasonably foreseeable projects and activities. The Project is expected to increase the amount of disturbed area over the existing conditions by a maximum of 69.5 km² (0.6%) within the CESA, resulting in a maximum disturbed area of 133.2 km² (1.2%) when combined with past, present, and reasonably foreseeable projects and activities.

The magnitude of cumulative change in habitat is low because it is a <1% change from existing conditions. The likelihood of the cumulative effect is Probable due to mitigation measures minimizing but not eliminating the potential for habitat loss. Changes in habitat are expected to occur throughout the CESA due to the spatial location of the projects and activities part of the assessment; therefore, the cumulative effect is regional in geographic extent. The effect is predicted to end following the completion of projects and activities in an area, and as a result, it is medium-term in duration. The change in habitat is continuous, as vegetation clearing will likely occur occasionally, but its effects will be continuous until vegetation regenerates. The effect of a change in habitat due to projects and activities within the CESA is predicted to have year-round Timing until vegetation can regenerate. It is likely that the regeneration of the affected habitat will occur over time following the completion of the projects and activities considered in the assessment and is anticipated to reverse the cumulative effect. The cumulative effects characteristics are summarized in **Table 8-34**.

Table 8-33. Cumulative Change in Habitat Effects from Existing and Project-Related Disturbances on Birds

Cumulative Effect Indicator	Scenario	Cumulative Effects Study Area
Total Surface Disturbance (Footprints)	Present	62.5 km² (0.6%)
	Project	69.1–69.5 km² (0.6%)
	Future	1.2 km² (0.0%)
	Total Cumulative Effect	132.8–133.2 km² (1.2%)

Table 8-34. Characterization of Cumulative Change in Habitat Effects on Birds

Criterion		Rating	Rationale
Magnitude		Low	The change in habitat across the CESA is predicted to be <1% over existing conditions.
Likelihood		Probable	Mitigation measures are expected to minimize but not eliminate the potential for a change in habitat.
Geographic Extent		Regional	Change in habitat quality is expected to occur across the CESA due to the location of the reasonably foreseeable projects and activities.
Duration, Frequency and Timing	Duration	Medium-term	The effect is expected to end after completing projects and activities in an area.
	Frequency	Continuous	Vegetation clearing required for projects and activities may occur occasionally, but the cumulative effect on birds will continue until vegetation regenerates.
	Timing	Year-round	The effect is expected to occur year-round due to changes in habitat remaining until vegetation regeneration.
Reversibility		Reversible	The regeneration of the affected habitat is expected to be reversible over time.

8.4.6.2.1 Context and Confidence

The context of Regional Land Use Planning and the confidence in accurately quantifying and predicting those effects were considered in the CEA for change in habitat on birds (**Table 8-35**). The effects characterization is consistent with the objectives of the Land Use Plans, and there is relatively high confidence that effects were accurately captured in the assessment. The total disturbance calculation may not have included all potential anthropogenic features, and there is a high degree of confidence that most disturbances were included. Therefore, the confidence in this CEA is high.

Table 8-35. Characterization of Context and Confidence in the Assessment of Cumulative Change in Habitat Effects on Birds

Criterion	Rating	Rationale
Context	Conforms to Regional Land Use Plans	Land Management Unit IV zones of the North Yukon and Peel Regional Land Use Plans are areas zoned for the highest level of development. The Project activities are consistent with the integrated resource management objectives of the LUPs.
Confidence	High	Characterizing the cumulative effect and its persistence has high confidence, as a precautionary approach was taken to quantify the change in habitat effect.

9 CARIBOU

Caribou were selected as a key Valued Environmental and Socio-Economic Component (VESEC) for the Project due to their cultural, ecological, and economic value to the Gwich'in people, including subsistence hunting. The Project occurs exclusively within the Porcupine Caribou Herd (PCH) range. Activities outside the Project Regional Study Area (RSA), such as personnel or equipment transport, will have limited overlap with other caribou herd ranges, e.g., Forty Mile Herd and Hart Herd along the Dempster Highway. Project-related traffic on public roads and highways will be infrequent (up to 12 trucks/vehicles per week) and a small proportion of the overall traffic. Therefore, this assessment focuses on the PCH and does not include other herds.

The PCH is a subpopulation of barren-ground caribou (*Rangifer tarandus groenlandicus*) known for its widespread distribution, large population aggregations, dramatic fluctuations in population size, and lengthy seasonal migrations (COSEWIC 2016). Within the North Yukon Regional Land Use Plan, the PCH is considered "*the most significant and culturally important wildlife resource in the planning region*" (Vuntut Gwitchin Government and Yukon Government 2009). Barren-ground caribou, including the PCH, have been assessed as Threatened by the Committee on the Status of Endangered Wildlife in Canada (COSEWIC 2016). However, the subspecies is not listed on Schedule 1 of the federal *Species at Risk Act*. In Yukon, barren-ground caribou are considered Vulnerable to Apparently Secure (Yukon Government 2020).

9.1 GENERAL ECOLOGY OF THE PORCUPINE CARIBOU HERD

A general understanding of the PCH's ecology and potential to interact with the Project are needed to frame and characterize effects appropriately. This section provides information on the herd's population size, seasonal ranges and distributions, movement patterns in the RSA, and habitat selection. The information comes from various primary publications and technical reports and includes results from the Project's baseline caribou study (**Section 6 Caribou** of **Appendix 9-A Wildlife Baseline**).

9.1.1 Subpopulation Size and Trends

Although most barren-ground caribou subpopulations are in decline (COSEWIC 2016), the PCH has increased in size over the last two decades. The last successful subpopulation survey in 2017 estimated 218,457 caribou (95% Confidence Interval [CI] = 202,106–234,808) (Porcupine Caribou Technical Committee 2019). Since the first survey in 1972, the PCH has had two periods of growth, with an interceding decline in the 1990s **(Figure 9-1**). During both periods of growth (1972–1989 and 2010–2017), the herd experienced an approximate 3.7% increase in abundance (Porcupine Caribou Technical Committee 2019).

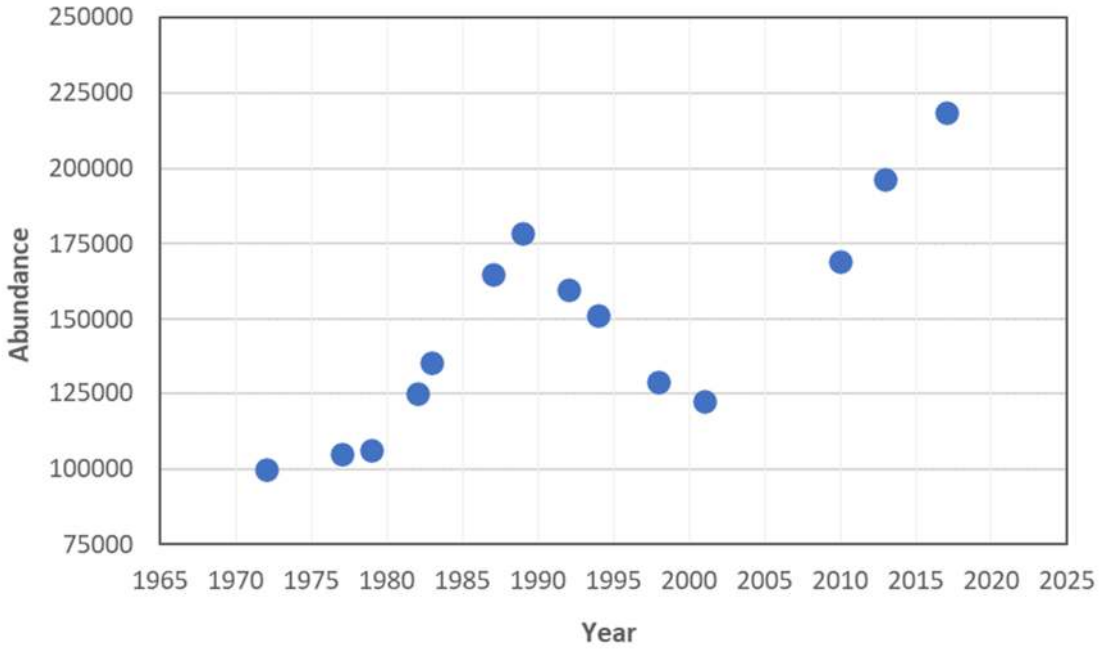

Figure 9-1. The Population Size of the Porcupine Caribou Herd from 1972 to 2017 (Porcupine Caribou Technical Committee 2019)

Large-magnitude fluctuations in population size are well-documented for barren-ground caribou (Bongelli et al. 2020). Subpopulations (herds) often experience >80% declines and >500% increases, which occur over several decades and caribou generations (COSEWIC 2016). Based on scientific studies and Traditional Knowledge, the time interval between peaks in abundance varies by approximately 30–80 years among subpopulations (Ferguson et al. 1998, Gunn 2003, COSEWIC 2016). Despite large-magnitude changes in the abundance of barren-ground caribou, there is still a poor understanding of how limiting factors regulate subpopulation dynamics. Predation, human harvest[10], parasites and disease, and food supply are limiting factors of barren-ground caribou (COSEWIC 2016). However, there has been no conclusive evidence to demonstrate a single, dominant factor that drives changes in abundance across herds and over time. Despite strong advocacy for certain factors by certain researchers (e.g., for predation by Bergerud [1996]), the weight of evidence suggests that subpopulation dynamics involve complex interactions among limiting factors that vary over time and space (Klein 1991, Whitten 1996).

After 50 years of PCH monitoring, the subpopulation has not exhibited fluctuations in size as large as other barren-ground caribou subpopulations (COSEWIC 2016). This may be due to the PCH's large annual and seasonal ranges and the diversity of habitats across these ranges (Russell et al. 1993, Whitten 1996). Whitten (1996) suggests that periods of decline are caused by nutritional stress and predation, exacerbated by adverse weather. Population growth during periods of favourable weather is dampened by a combination

[10] Human harvest is considered a natural population factor for barren-ground caribou because hunting has occurred for centuries (Sherry and Vuntut Gwitchin First Nation 1999, COSEWIC 2016). However, it is recognized that the nature of hunting has dramatically changed over the last century with the advent of high-powered rifles and snowmobiles.

of poor nutrition, predation, human harvest, and disease. There has been no evidence to suggest density-dependent regulation by the PCH (Whitten 1996).

9.1.2 Seasonal Ranges

Like most barren-ground caribou subpopulations, the PCH has a large annual range. Individuals make long-distance migrations, hundreds to thousands of kilometres in length, between seasonal ranges. These seasonal ranges can vary among and within years in response to variations in forage availability, snow cover, predation, or parasite risk (Russell et al. 1993). The PCH's annual range extends approximately 250,000 km² from Alaska, through Yukon, and into the western edge of Northwest Territories.

The PCH's long-distance migrations are necessary for key aspects of their life cycle. Eight (8) primary life cycle periods occur for the PCH (Porcupine Caribou Technical Committee 1993). Key information for the eight periods is summarized in **Table 9-1** (using information from Russell et al. 1993, Porcupine Caribou Technical Committee 1993, Ryder et al. 2007). The Porcupine Caribou Technical Committee (1993) assessed the relative importance of seasonal ranges using six criteria: energy balance, reproductive contribution, tolerance to disturbance, escape requirements, the intensity of use, and whether alternative habitats are available. Although all seasons are important to meeting the annual life requisites of the PCH, the calving and post-calving seasons are considered of the highest importance, and fall and winter are considered of the lowest importance (Porcupine Caribou Technical Committee 1993).

Typical patterns of seasonal range use by the herd from 1970–2016 are shown in **Map 9-1**. After calving on the north slope and Arctic coastal plains, the PCH typically splits in two, with portions of the herd moving southwest into Alaska and southeast into Yukon. Animals in the Yukon typically follow a clockwise movement through seasonal ranges, beginning at calving grounds on the north slope, moving to the British Mountains in summer, then to the Richardson Mountains in late summer, and dispersing widely and variably across northern Yukon in rut/ late fall and winter (but as far south as the Ogilvie Mountains) before returning to the northern coastal plains in spring. The PCH has historically overlapped the Project RSA in the rut/ late fall and winter periods (**Map 9-2**). However, the RSA overlaps a small portion of those seasonal ranges—6.0% during rut/ late fall and 6.5% during winter—and does not overlap with the most frequently used portions of those ranges.

Table 9-1. Key Life Cycle Periods for the Porcupine Caribou Herd

Season	Date	Characteristics	Importance*
Early, Mid, and Late Winter	Dec 1–Mar 31	The herd is most dispersed across two winter ranges: in Yukon, mainly south of the Porcupine River in boreal taiga, and in Alaska, centred in the Chandalar River/Arctic Village area. Winter range use varies annually, depending on snow depth and condition. Caribou at this time of year are relatively tolerant to human activity. In shallow to normal snow years, animals can gain weight.	4
Spring, Spring Migration, and Pre-Calving	Apr 1–May 31	Herd distribution varies depending on snowmelt; migration routes vary annually. Pregnant females typically have an energy deficit due to reduced forage once they leave the lichen-rich taiga.	3
Calving (cows)	Jun 1–10	Calving occurs on the coastal plain of northeast Alaska and, to a lesser degree, northwest Yukon. This area offers reduced predators and abundant spring forage; no alternative range is available. Cows are at the lowest point of physical condition and are least tolerant to human disturbance.	1
Post-Calving and Movement (cows)	Jun 11–30	As calves develop over the first two weeks of life, the cows and calves tend to aggregate into larger groups and increase movement rates to track the progression of plant green-up. The post-calving period imposes high energetic demands on lactating females, and cow/calf groups are relatively intolerant of disturbance. The post-calving range is primarily in Alaska, and cows that calved in Yukon tend to move west along the foothills into Arctic National Wildlife Refuge. Insect avoidance can affect distribution by the end of June.	1
Calving to Movement (bulls)	Jun 1–30	Bulls, non-pregnant cows, and subadults tend to concentrate east of the calving grounds in northern Yukon. Animals track green-up progression from the coastal plains to the northern foothills and into intermountain regions.	3
Early Summer	Jul 1–15	Cows continue requiring a high-energy forage intake for milk production, but insect avoidance drives distribution. Key areas selected for insect avoidance are the coastal plains adjacent to the Beaufort Sea (mostly cows/calves) and mountains in the Brooks and British Mountains (mostly bulls and cows without calves). Long-distance movements during this period are also insect avoidance behaviour.	2
Mid Summer	Jul 16–Aug 7	Mid-summer continues to be a period of high insect harassment. Two areas are consistently used: the northern Richardson Mountains in Yukon and the southern portion of the Brooks Range in Alaska. Females with calves may be in an energy-deficient state.	2
Late Summer and Fall Migration	Aug 8–Oct 7	As insect activity declines, the herd disperses widely but stays mostly north of the tree line until the latter part of the period—in Alaska south of the Brooks Range and Yukon north of the Porcupine River. Animals exhibit high feeding rates and gain fat for the winter.	3
Rut and Late Fall	Oct 8–Nov 30	The region where rut occurs has no affinity from year to year; rut occurs wherever the herd is along fall migration. In Yukon, distribution can occur from the southern Ogilvie Mountains to the Richardson Mountains.	4

*1 = highest importance, 4 = lowest importance.

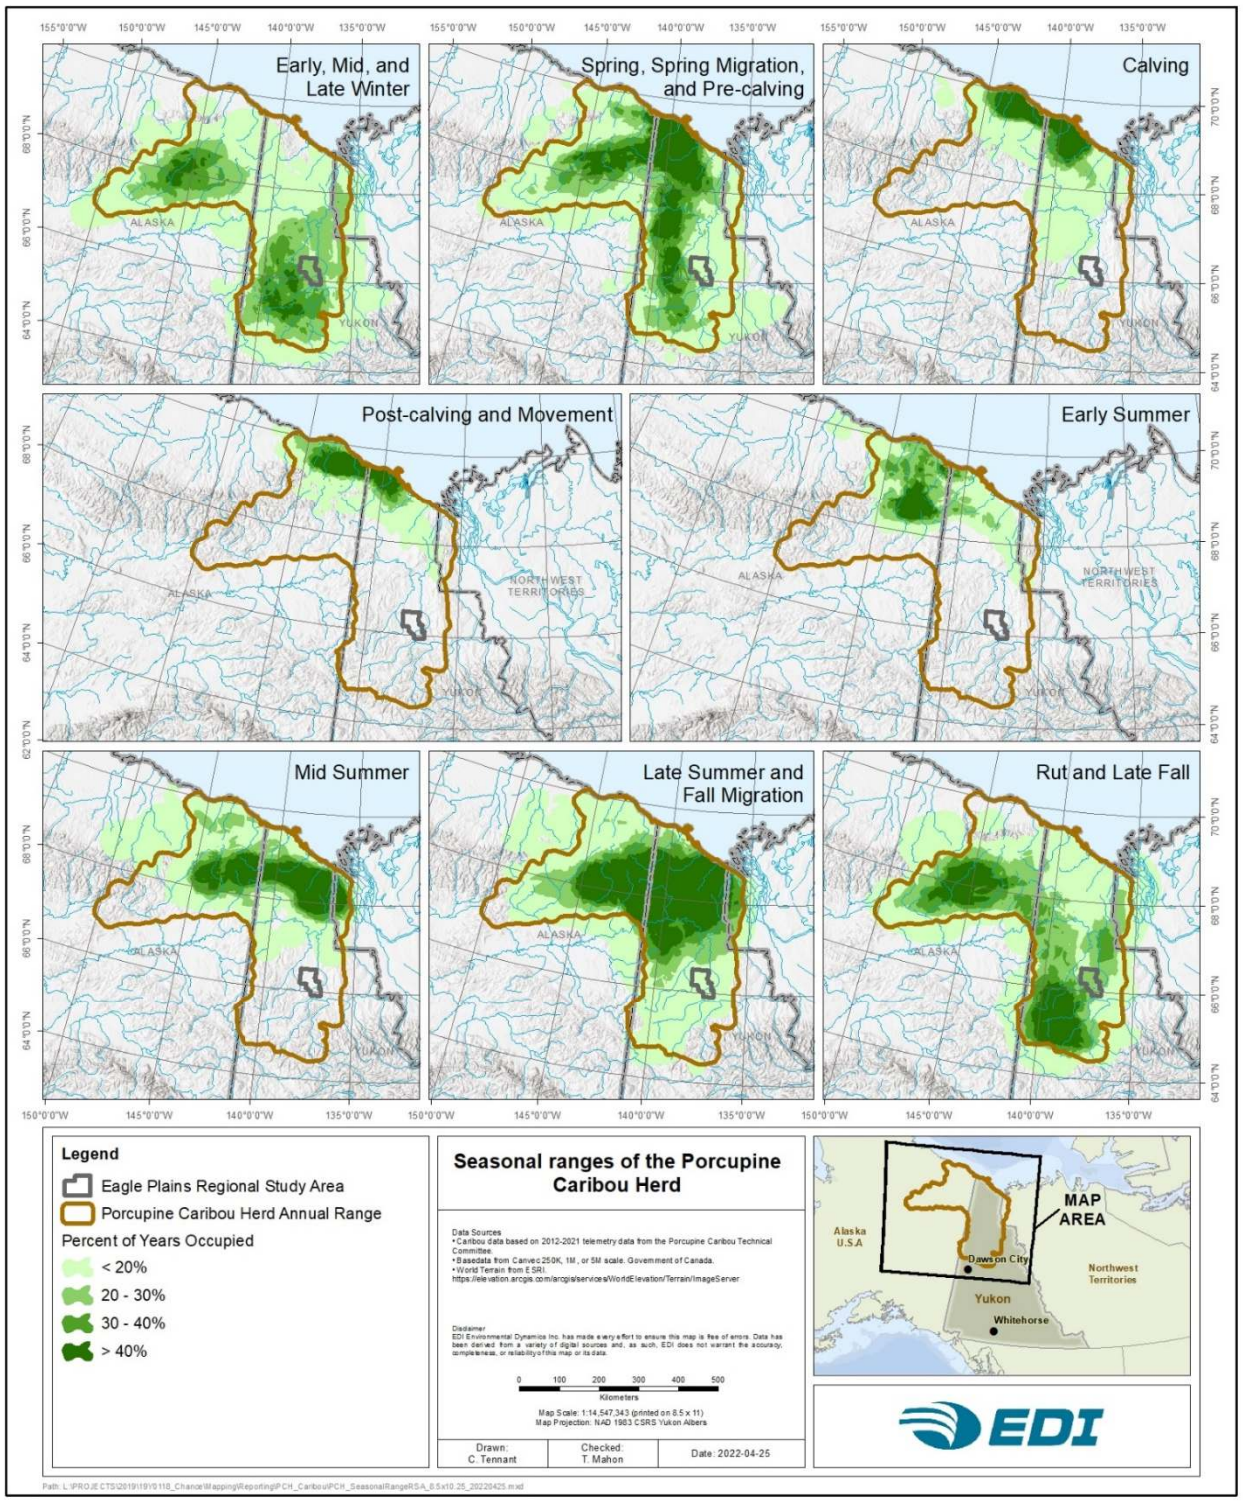
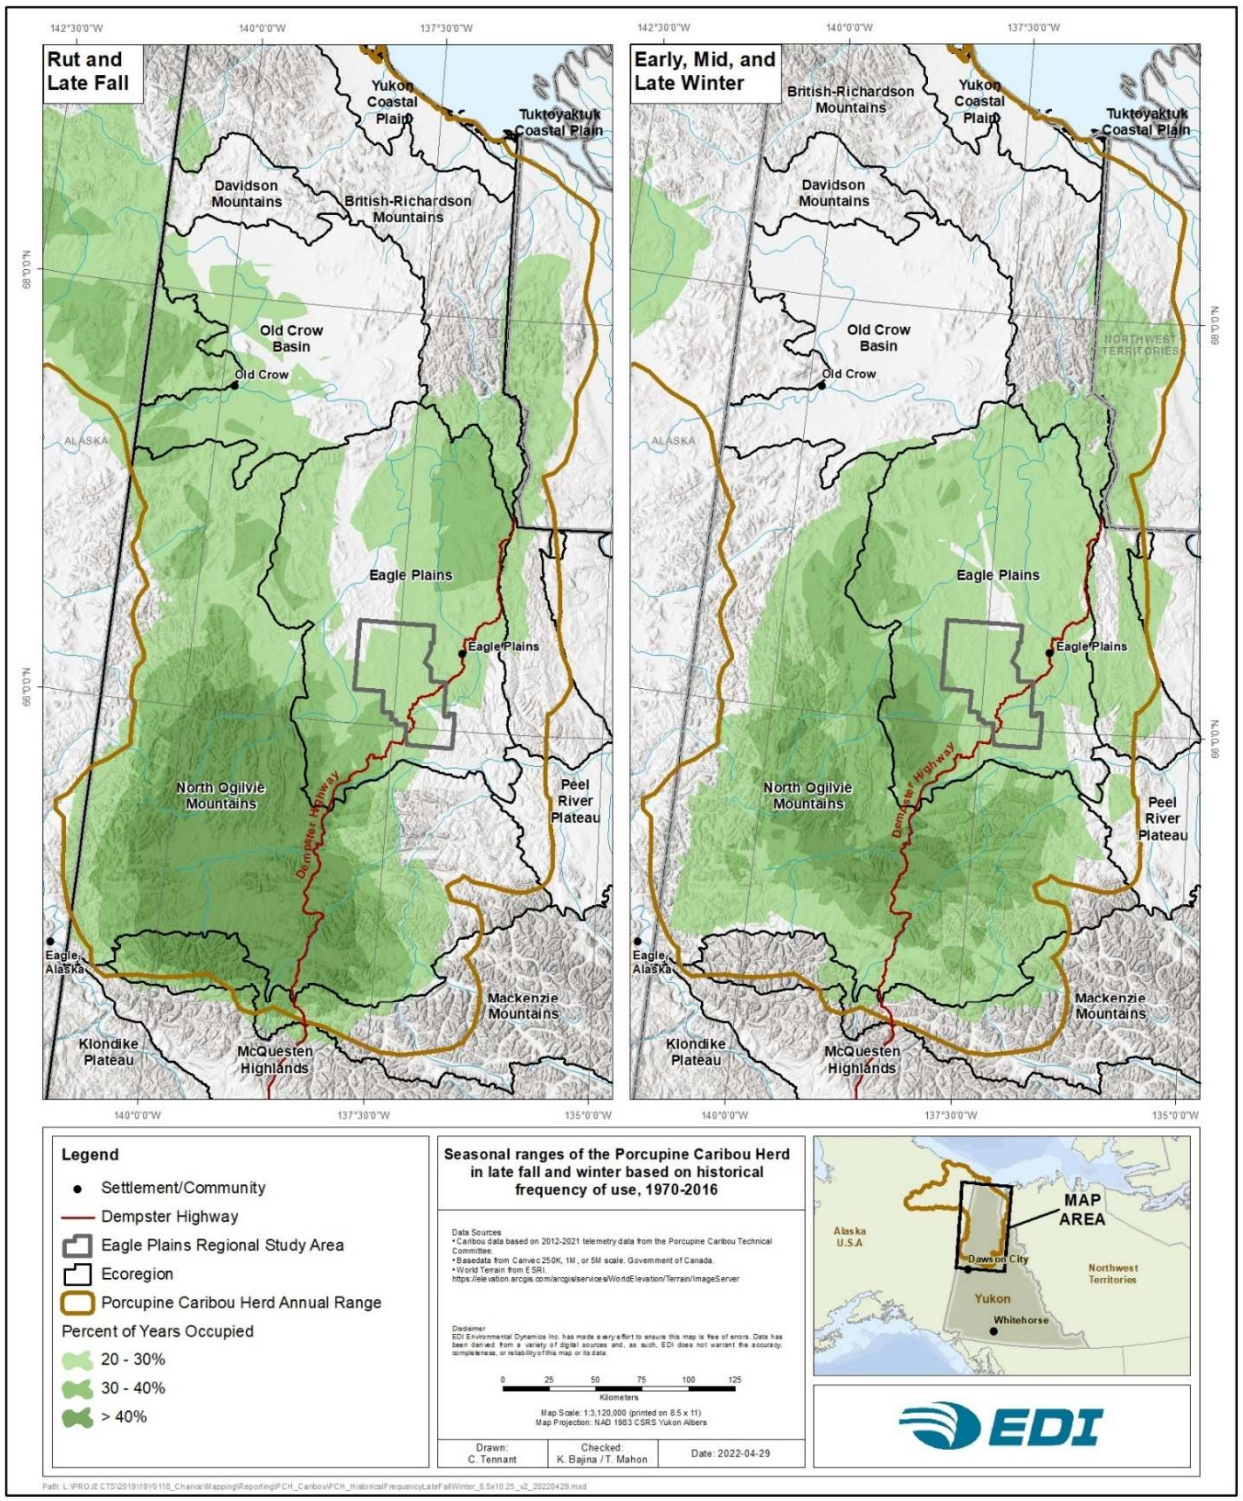


Map 9-1. Seasonal Ranges of the Porcupine Caribou Herd (ranges provided by the Porcupine Caribou Technical Committee), 1970–2016



Map 9-2. Seasonal Ranges of the Porcupine Caribou Herd in Late Fall and Winter Based on Historical Frequency of Use, 1970–2016

9.1.3 Movement Patterns

To better understand the factors affecting PCH caribou movement, two analyses were conducted as part of baseline studies using PCH telemetry data (2012–2021) (**Section 6 Caribou** of **Appendix 9-A Wildlife Baseline**). First, daily movement rates and residency times were calculated for Porcupine caribou in the RSA and across the broader seasonal ranges. Residency times refer to how long caribou were present in the RSA or similarly sized parts of the broader seasonal ranges. Movement and residency within the RSA were compared to other equal-sized areas (or cells) in the rut/ late fall and winter ranges. Second, movement (migration) paths were delineated within and adjacent to the RSA.

The analyses indicated that Porcupine caribou typically make movements of several kilometres per day in both rut/ late fall and winter and rarely spend multiple days in the same location. Daily movement rates and residency times are summarized in **Table 9-2.** Rut/ late fall daily movements (9.0 km/day in the RSA) were substantially greater than during winter (4.0 km/day). Residency times were shorter during rut/ late fall than winter and shorter in the RSA compared to the broader seasonal ranges. The combination of faster daily movements and shorter residency times in the RSA to the broader seasonal ranges suggests the PCH's historical transient use of the RSA.

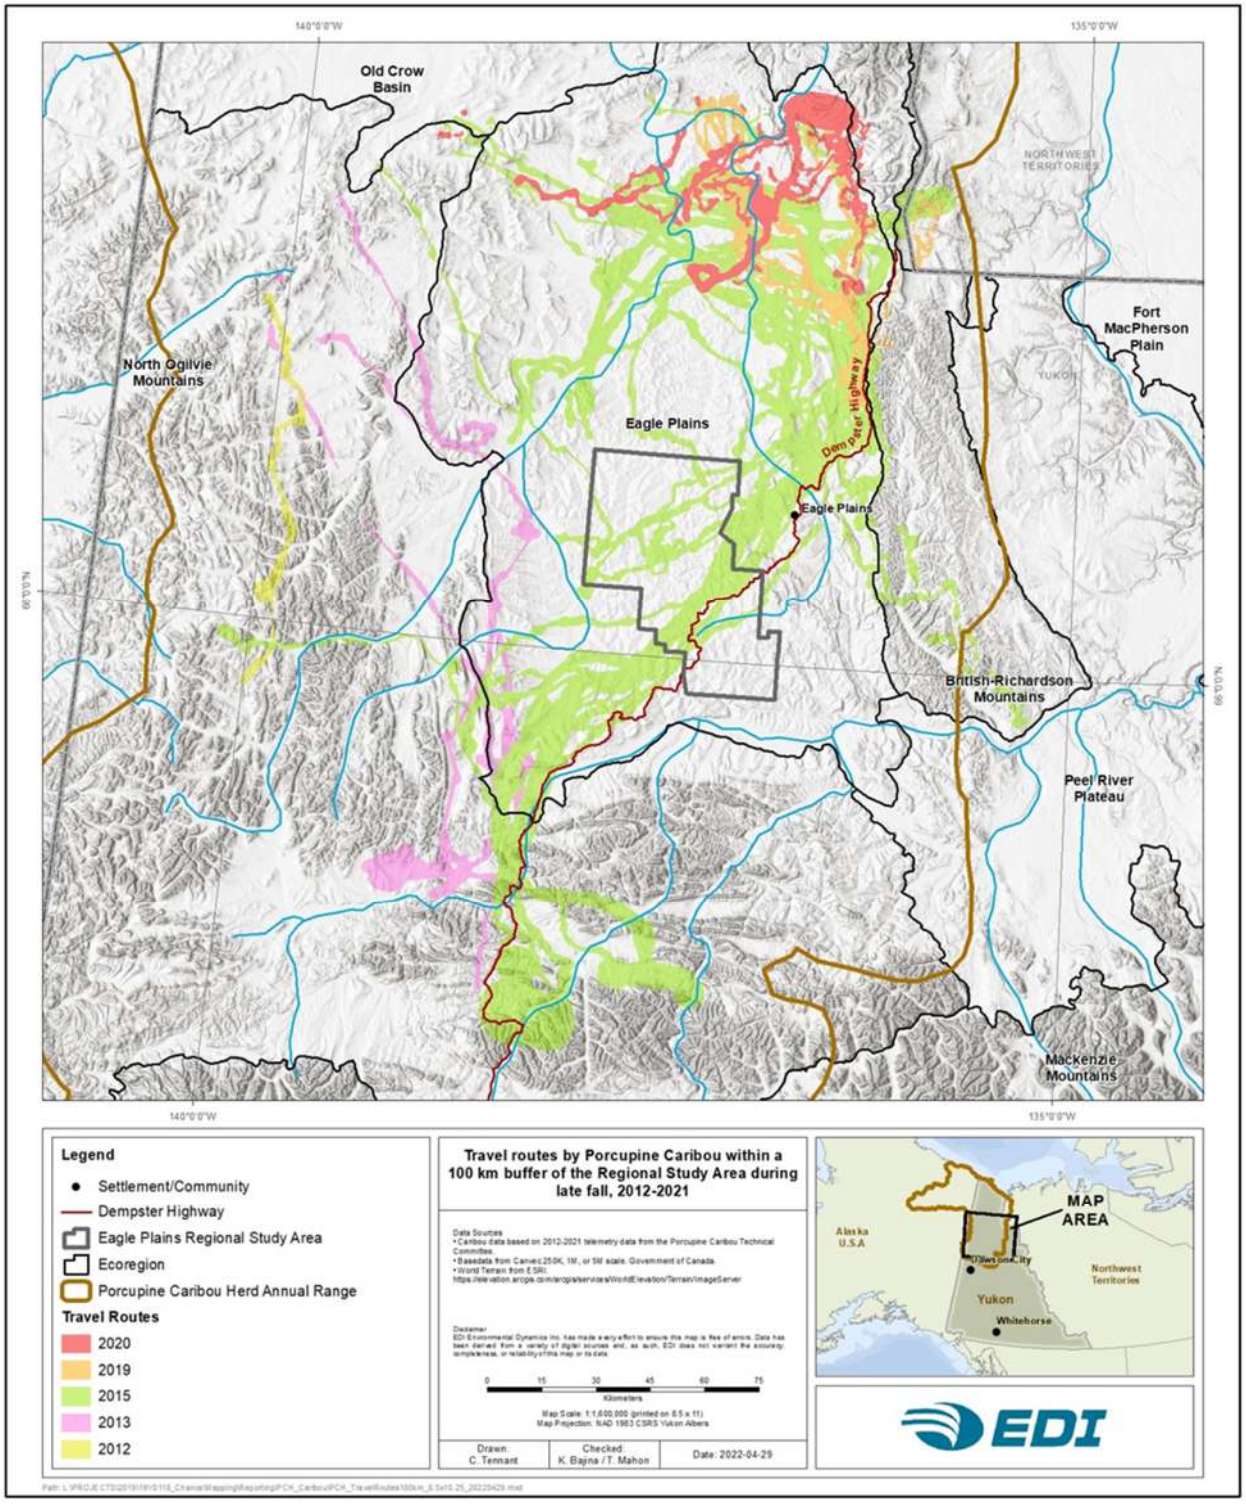
Global Positioning System (GPS) collar data (2012–2021) demonstrated that the only time caribou travelled through the RSA during the rut/ late fall season was in 2015; 14 collared caribou made clear, directed movements along the height-of-land parallel to the Dempster Highway, from the northeast to the southwest (**Map 9-3**). Most caribou appeared to avoid crossing the Dempster Highway while travelling through the Eagle Plains region; however, all animals eventually crossed the highway farther south, in the Ogilvie Mountains. The caribou moving through Eagle Plains crossed several historical two-dimensional (2D) seismic lines and winter roads/trails (mostly aged 35-years or older) and a large three-dimensional (3D) seismic grid (established 2013–2014) within the RSA.

Table 9-2. Mean Daily Movement Rates and Residency Times of the Porcupine Caribou Herd in the Project Regional Study Area and in Similarly Sized 50 km x 50 km Cells Covering Late Fall and Winter Range Extents

Season	Scale[1]	Daily Movement (km/day)		Residency Time (days)[2]	
		Mean	Standard Error	Mean	Standard Error
Late Fall	Project RSA (2,387 km² total)	9.0	± 0.6	4.5 (8.3%)	± 0.8
	Late Fall Range (88,149 km²) (2,500 km² per cell) – 53 cells total	15.0	± 2.1	7.7 (14.2%)	± 0.6
Winter	Project RSA (2,387 km² total)	4.0	± 0.6	15.69 (12.9%)	± 5.1
	Winter Range (65,077 km²) (2,500 km² per cell) – 40 cells total	4.8	± 0.5	25.93 (21.3%)	± 2.1

[1] Late fall and winter ranges were subsampled using 2,500 km² cells (approximately the same size and the RSA) to facilitate estimation of mean and variance. Estimates of mean and variance within the RSA are derived from differences in rates and residencies of individual caribou.

[2] Percent of the season indicated in brackets. Total days: late fall = 54 days, winter = 122 days.



Map 9-3. Travel Routes by Porcupine Caribou Within a 100 km Buffer of the Project Regional Study Area During Late Fall, 2012–2021

During this temporal extent (2012–2021), collared caribou were only present during late fall of 2012, 2013, 2015, 2019, and 2020.

9.1.4 Diet and Habitat Selection

During the growing season, barren-ground caribou forage on grasses, sedges, forbs, lichens, and shrubs. However, during winter, lichens constitute the primary forage of most barren-ground caribou populations (COSEWIC 2016). In a study over three winters, the composition of PCH fecal samples was similar and, on average, consisted of 64% fruticose lichens, 11% evergreen shrubs, 8% moss, 6% horsetails, and 5% foliose lichens (Russell et al. 1993).

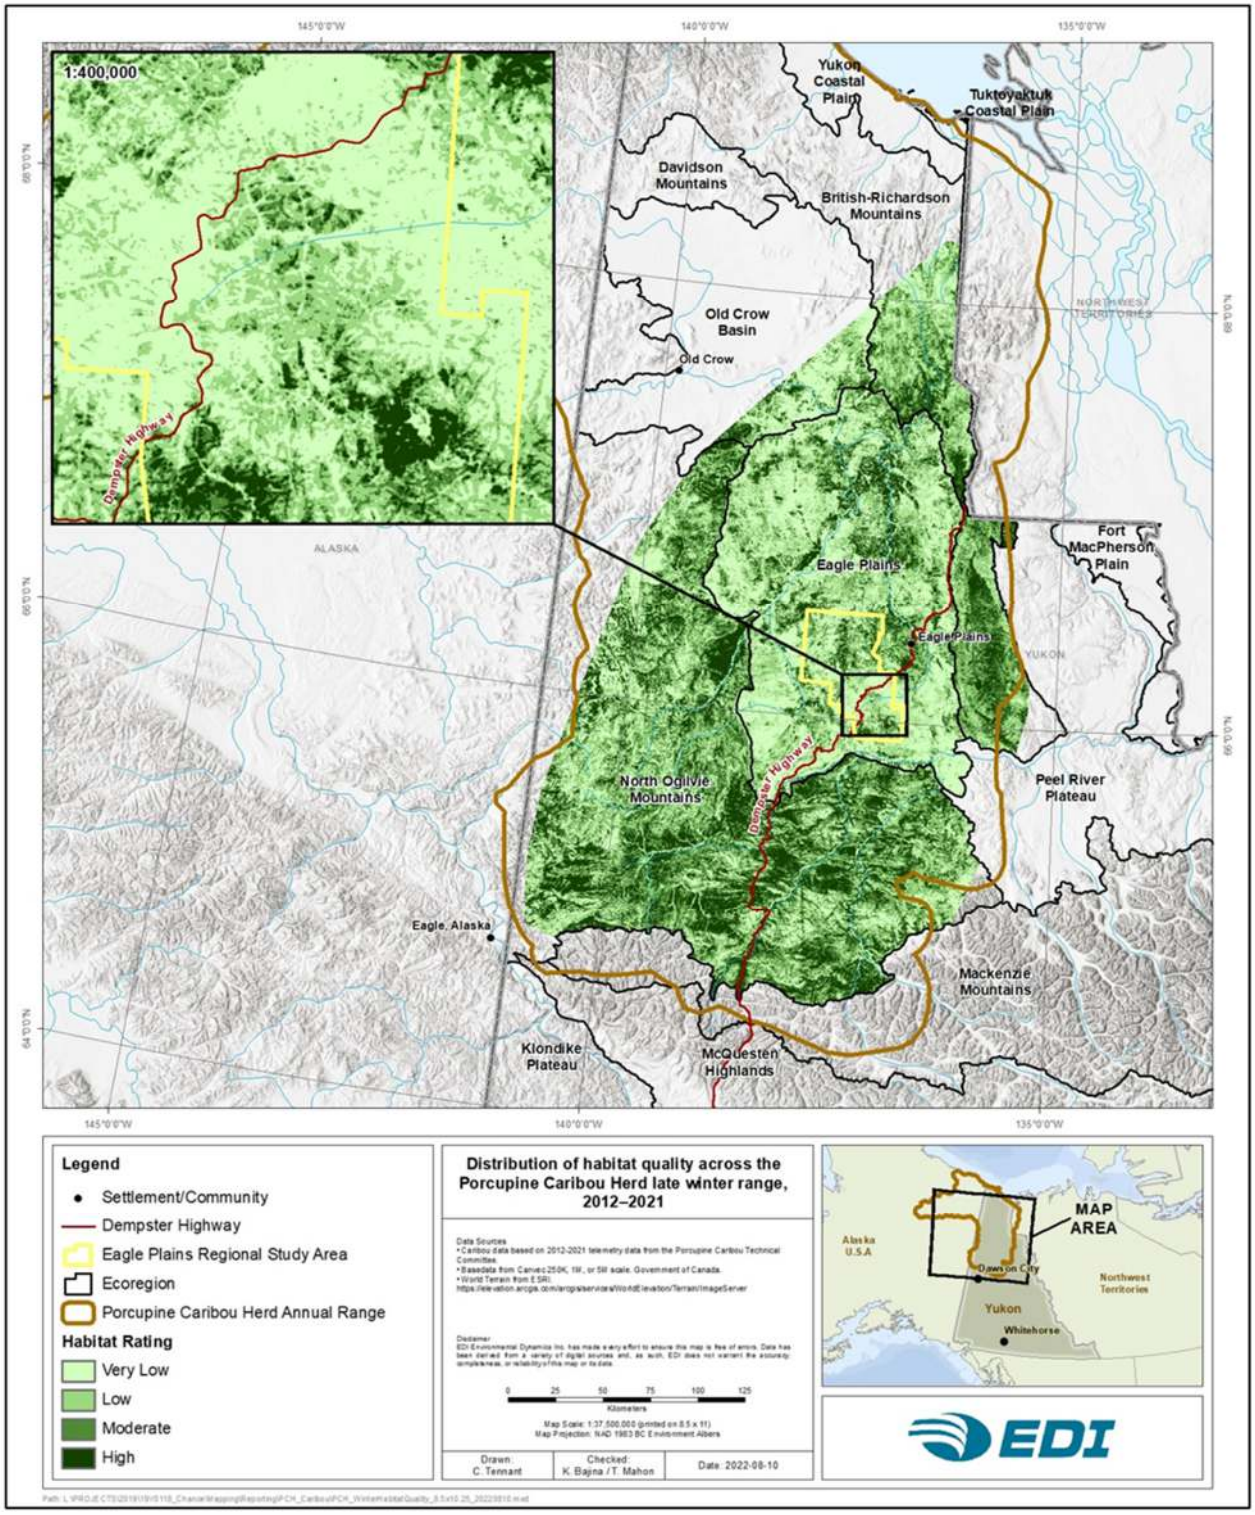
Generally, lichen biomass in the taiga is greatest in open conifer stands that are 125–175 years old (Klein 1982). Lichen biomass is often greatly reduced following wildfire. However, Russell et al. (1993) found that lichen biomass in the PCH range varied across stand ages. Stands <50 years old often had moderate-to-high lichen biomass, suggesting that young stands may contribute more to the PCH's lichen forage than other herds. Russell et al. (1993) emphasized the importance of a mosaic of stand age classes, resulting primarily from wildfire, to maintaining lichen biomass at the regional level over time. Although habitat selection is often driven by forage availability, especially in winter, caribou habitat selection is also influenced by the need to reduce predation risk (Latham et al. 2011a) and minimize exposure to insect harassment during summer (Russell and Nixon 1990).

The Project's PCH baseline studies involved quantifying habitat selection during rut/ late fall and winter (**Section 6 Caribou** of **Appendix 9-A Wildlife Baseline**), which required the development of Resource Selection Functions (RSFs) (Manly et al. 2002). Data for the RSFs consisted of GPS collar locations from 2012–2021 for 164 caribou during rut/ late fall and 172 caribou during winter. Spatial habitat data included a set of plant functional type layers (light macrolichens, graminoids, forbs, evergreen shrubs, deciduous shrubs, and conifer trees), elevation, aspect, slope, terrain ruggedness, and distance to waterbodies >1 hectare (ha). PCH caribou tended to select and avoid similar resources in both rut/ late fall and winter, though the range of selected habitats was narrower in winter.

Key covariates in models for both seasons that were statistically significant (i.e., $P < 0.05$) included light macrolichen cover (positive coefficient), conifer tree cover (negative coefficient), slope percent (negative coefficient), elevation (variable in fall and winter), and aspect (greater selection for south- and west-facing slopes). Coefficients for lichen cover had the greatest magnitude, which suggests that the selection of lichen is the primary driver of habitat selection during rut/ late fall and winter.

The RSFs were used to derive habitat quality maps with four rating classes (Very Low, Low, Moderate, and High), which were determined by assessing selection ratios across RSF predictions. The distribution and proportion of selected habitat (Moderate and High) were then examined within the RSA and broader seasonal ranges (**Map 9-4**). The proportion of selected habitat during late fall was equivalent between the RSA (0.4) and the broader range (0.4 ± 0.03) but was less in the RSA (0.3) than the broader range during winter (0.4 ± 0.03).

Selected habitat, especially areas of High quality, were mostly dependent on the amount and distribution of light macrolichen cover.



Map 9-4. Distribution of Habitat Quality Across the Porcupine Caribou Herd Late Winter Range, 2012–2021

The map inset shows the habitat in the southern half of the RSA in finer resolution. High ratings correspond mostly to mature open canopy spruce stands with high ground lichen cover; low ratings correspond mostly to recent burns.

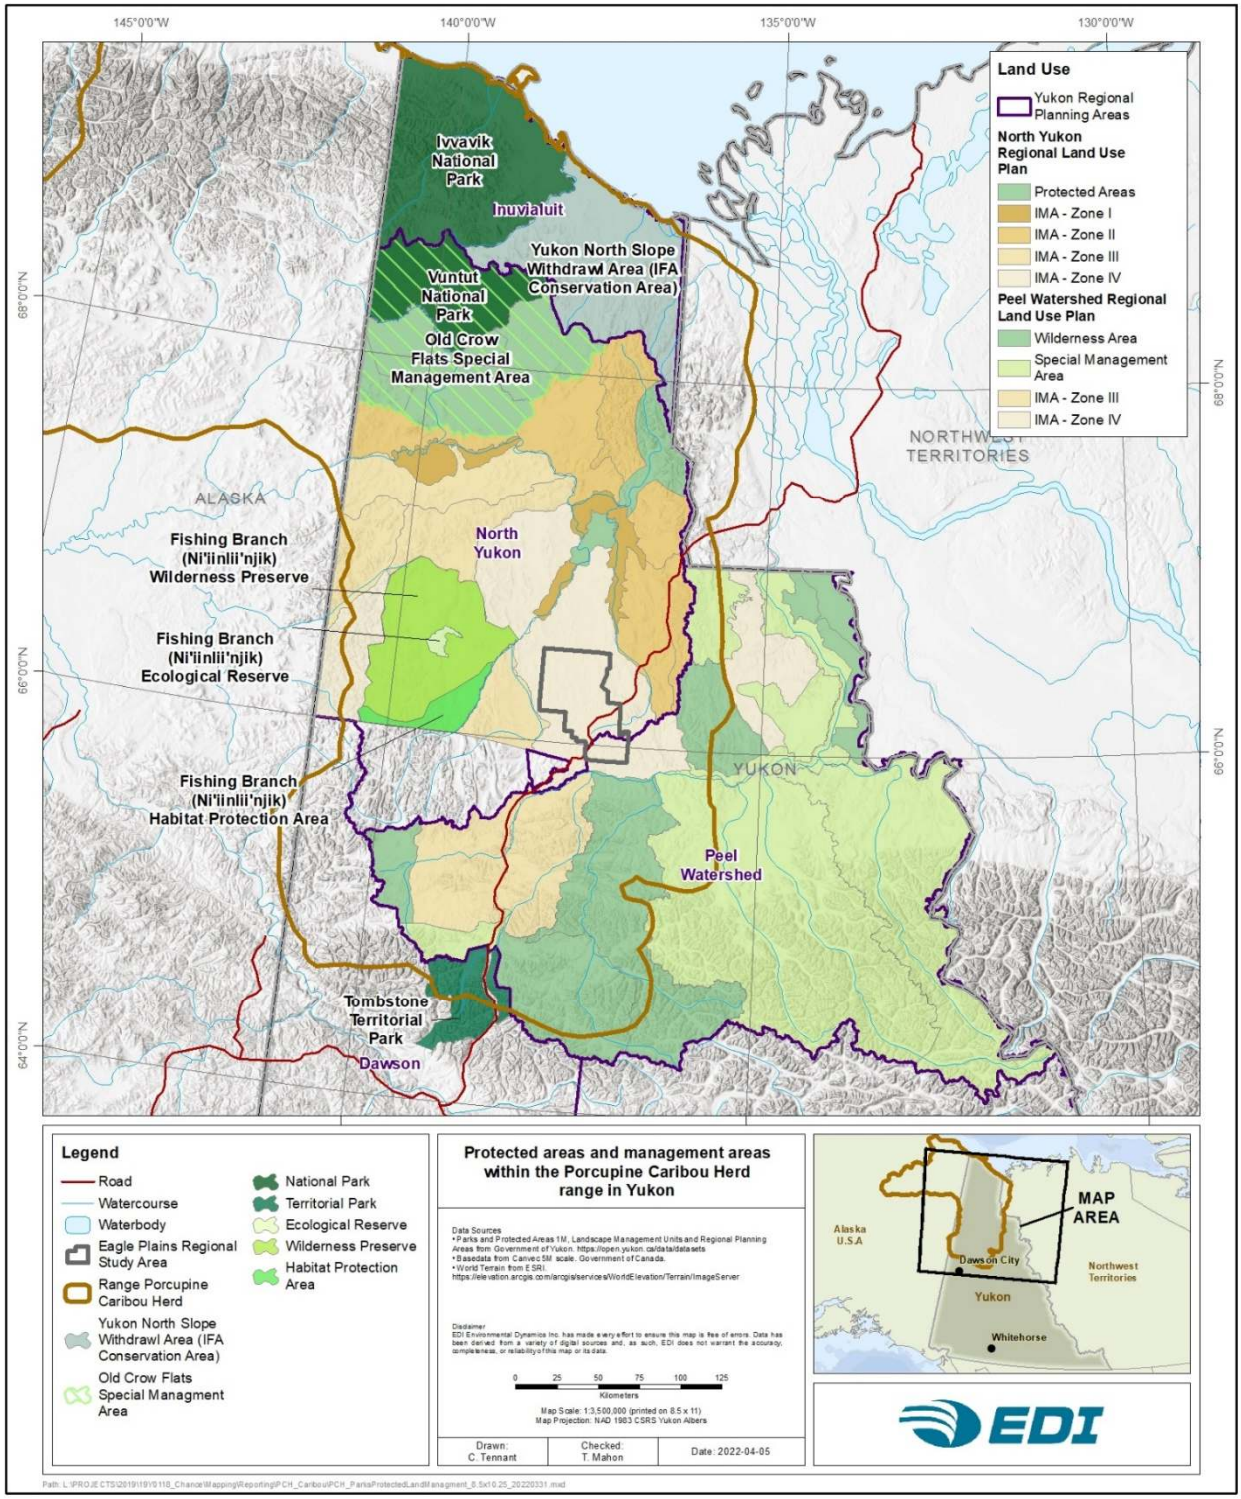
9.2 PORCUPINE CARIBOU MANAGEMENT AND CONSERVATION

There is a long history of co-management of the PCH among indigenous, state, territorial and federal governments in Canada and the United States of America (USA). Canada and the USA co-manage the herd under the *Agreement Between the Government of Canada and the Government of the United States of America on the Conservation of the Porcupine Caribou Herd* (Government of Canada and Government of the United States of America 1987). There are two primary management boards for the PCH: the International Porcupine Caribou Board (IPCB), comprised of Canadian and American representatives, and the Porcupine Caribou Management Board (PCMB), which is a co-management board for the Canadian portion of the herd's range, formed under the *Porcupine Caribou Management Agreement* (Government of Canada et al. 1985). The IPCB and the PCMB have developed multiple conservation plans for the PCH focused on population management and land use management, including:

- Plan for the International Conservation of the Porcupine Caribou Herd (International Porcupine Caribou Board 1993);
- *Wildlife Conservation and Management Plan for Yukon North Slope* (Wildlife Management Advisory Council [North Slope] 2002);
- *Harvest Management Plan for the Porcupine Caribou Herd in Canada* (Porcupine Caribou Management Board 2010a) and an associated *Implementation Plan* (Porcupine Caribou Management Board 2010b); and,
- Porcupine Caribou Herd Strategic Framework 2015–16 to 2019–20 (Porcupine Caribou Management Board 2016).

The 1987 international agreement provided for forming a joint technical committee, now known as the Porcupine Caribou Technical Committee (PCTC), to coordinate research and monitoring activities and to advise the IPCB and the PCMB on scientific matters surrounding the herd. The PCTC leads most monitoring and research work on the PCH, including population and demographic monitoring, seasonal movement monitoring (via GPS telemetry tracking), caribou body condition monitoring, habitat and human disturbance assessments, and annual snow surveys. Monitoring results are typically provided to the PCMB and the IPCB via annual reports (e.g., Porcupine Caribou Technical Committee 2019) and presentations at the annual harvest meetings.

The portion of the PCH annual range that occurs within Yukon is protected by a network of parks, special management areas, conservation areas, wilderness areas, protected areas, ecological preserves, habitat protection areas, and Integrated Management Area (IMA) zones within the North Yukon Regional Land Use Plan (NYRLUP; Vuntut Gwitchin Government and Yukon Government 2009) and the Peel Watershed Regional Land Use Plan (PWRLUP; Peel Watershed Planning Commission 2019) (**Map 9-5**). In total, 54% of the annual range of the PCH within Yukon falls within some type of protected area where industrial activity is prohibited, 36% of the annual range occurs within regional LUP IMA zones where development is limited, and any land management zonation does not cover 9% of the annual range.



Map 9-5. Protected Areas and Management Areas Within the Porcupine Caribou Herd Range in Yukon

9.3 ASSESSMENT INDICATORS AND ASSESSMENT PARAMETERS

Based on the PCH's ecology and possible interaction with the Project RSA (Section 9.1 General Ecology of the Porcupine Caribou Herd), the Project has the potential to affect PCH habitat, movement, mortality, and energetics. Details on each of these factors and the associated assessment parameters are summarized in **Table 9-3**.

Table 9-3. Indicators and Assessment Parameters for the Porcupine Caribou Herd and the Potential Effects of the Eagle Plains Exploration Project

Assessment Indicator	Pathway	Assessment Parameters/Approach
Direct Habitat Effects	Vegetation clearing associated with Project developments (e.g., well sites, winter access roads, seismic) is expected to result in direct habitat loss.	Quantitative assessment of the change in (modelled) suitable habitat based on development footprints.
Indirect Habitat Effects	Sensory disturbance associated with Project activities may cause caribou to avoid a Zone of Influence (ZOI) around work sites, resulting in temporary, indirect habitat loss.	Quantitative assessment of the change in (modelled) suitable habitat based on a Zone of Influence associated with annual work areas.
Movement Effects	Sensory disturbance associated with Project activities may cause caribou to avoid a Zone of Influence around work sites, potentially affecting movement patterns.	Qualitative assessment of the potential effects on movement based on a Zone of Influence associated with annual work areas. Changes to local and regional movement patterns are discussed.
Direct Mortality Effects	Vehicle travel has the potential to cause direct caribou mortality via vehicle collisions.	Mitigation measures are expected to reduce direct caribou mortality to a negligible level. As such, these direct effects are not formally assessed as part of the effects characterization.
Indirect Mortality Effects	The creation and use of linear features for the Project has the potential to cause indirect mortality of caribou by wolves and humans (facilitated predation).	Qualitative assessment that considers the extent of linear feature developments and PCH ecology in the context of the Eagle Plains ecoregion. Comparisons are made to boreal regions where the effects of linear features have been well documented.
Energetics Effects	Indirect habitat effects and altered movement could have cascading effects on the energetic output of caribou.	Effects on caribou energetics are expected to be low given the timing and magnitude of potential effects due to the Project. As such, these effects are not formally assessed as part of the effects characterization.

9.4 PROJECT INTERACTIONS AND POTENTIAL EFFECTS

9.4.1 Interactions

The potential for the Project to interact with and affect caribou was assessed by systematically reviewing each of the components listed in the Project description (**Table 9-4**). The Project includes several components that have the potential to interact with caribou. Each of these components received scores (0 = no interaction; 1 = minor interaction; 2 = substantial interaction) based on the expected interaction between caribou and that component. Only component-effect interactions with a score of 2 are considered in residual effects characterization, whereas lower scores are associated with effects that are small (immeasurable) or negligible (**Table 9-4)**.

Table 9-4. Expected Interactions Between Caribou and the Eagle Plains Exploration Project and the Resulting Potential Effects

Project Component / Activity	Direct Habitat	Indirect Habitat	Movement	Direct Mortality	Indirect Mortality	Energetics
Engagement	0	0	0	0	0	0
Seismic Exploration	2	2	2	0	2	1
Drilling Exploration	2	2	2	0	0	1
Extended Flow Testing (EFT)	0	2	2	0	0	1
Well Maintenance (Workovers)	0	2	2	0	0	1
Access Roads	2	2	2	1	2	1
Mix Bury Cover (MBC) Construction and Operation	2	2	2	0	0	1
Central Processing Facility (CPF)	2	2	2	0	0	1
Airstrip	2	2	2	0	0	1
Water Withdrawal	0	2	2	0	0	1
Transportation	0	2	2	1	0	1
Camp	2	2	2	0	0	1
Reclamation and Closure	2	2	2	0	0	1

Notes:
0 = no interaction
1 = minor interaction with caribou is possible, but small immeasurable effect (e.g., possible slight behavioural response, no vegetation effects). Designates a summary of effects addressed in the effects assessment as a discussion. This rating does not lead into residual effects characterization.
2 = substantial interaction with caribou, designates a more detailed assessment of potential effects. Carry forward into residual effects characterization.

Major Project components include seismic exploration, well sites, winter access roads, a winter air strip, and primary and secondary camp locations. Four main disturbance types common across most Project components have potential mechanisms (pathways) to affect caribou: vegetation clearing, access development, sensory disturbances, and vehicle operations (**Table 9-5**). Details associated with each potential effect are provided in the following sections. Their spatial and temporal overlap fundamentally determines the potential for interaction between the Project and the PCH. Where there was potential for the Project to interact with caribou due to spatial and temporal overlap, potential mechanisms (pathways) of effects on caribou were determined based on the details of the Project components, environmental conditions in the Eagle Plains ecoregion, and key aspects of PCH ecology. Determination of mechanisms of effects considered fundamental principles (e.g., that vegetation clearing can affect habitat) and detailed studies of specific types of effects in the literature (e.g., the effects of linear features on caribou mortality). The evaluation considered both direct and indirect effects of the Project.

Table 9-5. Potential Effects on the Porcupine Caribou Herd Associated with Disturbances from the Eagle Plains Exploration Project

Disturbance Type	Project Components	Potential Effects on Caribou
Vegetation Clearing	Most Project components are expected to involve some level of vegetation clearing during their development, including seismic lines, well sites, winter access roads, secondary camps, and the airstrip.	• Direct habitat effects via vegetation clearing • Indirect mortality via apparent competition[11]
Access Development	Seismic lines and the winter access roads used to access all Project components are expected to result in a network of cleared linear features that may enhance access and travel for human hunters and wolves.	• Indirect mortality via facilitated predation
Sensory Disturbance	All Project components are expected to produce a variety of sensory disturbances associated with human and mechanized activity that may cause caribou to avoid those areas plus a ZOI around them.	• Indirect habitat effects via sensory disturbance • Movement effects via sensory disturbance • Energetics effects via sensory disturbance
Vehicle Operations	Vehicle travel along winter access roads and trails can pose a mortality risk to caribou.	• Direct mortality effects via vehicle collisions

Key factors considered when determining Project interactions and potential effects include temporal overlap, spatial extent, caribou movement rates, and land use planning context (**Table 9-6**). Overlap between the Project and PCH will likely occur during the herd's rut/ late fall and winter seasons (October to April, annually) when the herd is present in Eagle Plains. However, rut/ late fall and winter are considered the seasons of lowest concern (**Table 9-1**; Porcupine Caribou Technical Committee 1993). During rut/ late fall and winter, caribou are typically in prime body condition, experience neutral to positive energy balances, do not experience stress from heat and insect harassment, and are least sensitive to human disturbances.

[11] For caribou, apparent competition refers to the situation where predation rates rise due to an increase of wolves in response to elevated alternative prey (moose) that results from increased forage (shrubs) due to forest clearing.

Furthermore, the Project RSA (2,400 km²) constitutes a relatively small portion of the PCH's rut/ late fall and winter ranges in Yukon, 6.0% and 6.5%, respectively.

During rut/ late fall and winter, the PCH is typically widely dispersed in small and medium-sized groups (Russell et al. 1993). In any given year, Project activities will be clustered to annual work areas so that disturbances are limited to approximately a third (32%) of the RSA, reducing the degree of overlap with the PCH rut/ late fall and winter ranges to about 2% of their total extent in Yukon. The 2% area of overlap could correspond to 2,180 caribou with the potential to interact with the Project. This calculation considers the latest population estimate of 218,000 caribou and assumes that approximately half the herd winters in Yukon. During rut/ late fall and winter, caribou tend to wander continually, travelling several kilometres daily and covering long distances over time. They do not seem to settle in one area for an extended period, i.e., individuals do not have central home ranges during these seasons. For caribou that might use the RSA, their residency would likely last only a small portion of the rut/ late fall and winter seasons. Overall, the relatively small spatial and temporal overlap between the Project and PCH would be expected to limit the exposure of individual caribou to Project-related disturbances.

Table 9-6. Key Factors Influencing the Degree and Nature of Potential Interactions Between the Project and the Porcupine Caribou Herd

Factor	Details
Temporal Overlap	The PCH are migratory and generally occur in the Eagle Plains ecoregion during the rut/ late fall (mid-October through November) and winter seasons (December through April). Project activities are expected to overlap the period when the PCH are present.
Spatial Extent	The Project RSA overlaps the rut/ late fall and winter ranges of the PCH. However, the RSA covers a relatively small portion of those ranges: 6.0% during rut/ late fall and 6.5% during winter. The RSA does not overlap with the most frequently used portions of those ranges.
Caribou Movements	The PCH are widespread and tend to wander continually during rut/ late fall and winter (15.0 km/day and 4.8 km/day, respectively). When caribou occur in the RSA, it is typically only for a small portion of the season: 4.5 days during rut/ late fall (54 days total) and 15.7 days during winter (122 days total). This has important implications for assessing and mitigating potential Project effects on the PCH.
Regional Land Use Planning Context	The Project falls within Integrated Management Area Zone IV of the North Yukon Regional Land Use Plan and the Peel Watershed Regional Land Use Plan. Zone IV has lower ecological and cultural values and the highest permissible development of the four IMA zones (37% of the PCH winter range is protected, and 29% is within more restrictive IMAs).

9.4.2 Direct Habitat Effects

As part of caribou baseline studies, rut/ late fall and winter habitat selection by the PCH was quantified using RSFs (see **Section 6 Caribou** of **Appendix 9-A Wildlife Baseline**). RSFs were fit to data that included locations from GPS-collared caribou (2012–2021) and location-specific habitat variables on the landscape. From RSF model predictions, spatially explicit habitat maps were developed across the seasonal ranges. The preferred habitat in both seasons consisted of a high cover of macrolichens in open conifer stands, undisturbed by fire, consistent with previous studies of diet and habitat use by the PCH (Russell et al. 1993). Many Project components require vegetation clearing, which could directly affect such caribou habitat. Several of these Project components are expected to consist of long, relatively narrow footprints (linear features), including seismic lines (2–5 metres [m] wide), winter access roads (5–15 m

wide), and an airstrip (approximately 50 m wide). Non-linear features include well sites (<2 ha) and secondary camps/staging areas (<4 ha). Vegetation clearing associated with all Project components will occur in winter and be limited to trees and tall shrubs. However, it is important to note that approximately 47% of the RSA has already been disturbed by fires <40-years old, which also affects caribou habitat and forage (lichen).

The effects of vegetation clearing on caribou forage appear mostly limited to footprint disturbances. Although some studies in temperate and tropical forests have observed significant edge effects adjacent to large openings, such as clearcuts, edge effects associated with linear features in boreal ecosystems are limited (Dabros et al. 2018). One study of the edge effects of conventional seismic lines (>7 m wide) on vegetation in boreal peatlands found that, although lichen was virtually absent on the seismic lines, the percent cover of lichens in the adjacent forest was highest immediately adjacent to the lines, apparently responding positively to the increased light and drier conditions associated with the edge (Dabros et al. 2022). A similar study of low-impact seismic lines (≤3 m wide) in upland boreal forest found that species diversity of herbaceous plants was reduced within 15 m of lines, but that percent cover of different vegetation types, including lichen, was not reduced from the seismic line edge out to 75 m (Dabros et al. 2017).

Photo 9-1. Macrolichen on a 3-Dimensional Receiver Line in the Regional Study Area Nine Years After Vegetation Clearing

This linear feature is one of many in a 3D seismic grid established in 2013–2014 as part of the Northern Cross exploration program.

9.4.3 Indirect Habitat Effect

Indirect habitat loss is a temporary effect where caribou avoid suitable habitat due to adjacent human disturbance. For example, caribou may avoid a well site by several hundred metres even though the habitat disturbance and human activity are limited to the 2-ha extent of the well site itself. The area over which this effect occurs is referred to as a ZOI.

The ZOI distances estimated for caribou vary widely from a few hundred metres to tens of kilometres (see summary of studies in **Section 6 Caribou** of **Appendix 9-A Wildlife Baseline**). Estimates of ZOI distances may vary with disturbance factors (e.g., geographic area, habitat, season, year, weather, herd, and sex/age classes) and study-related factors (e.g., caribou sample size and analytical methods). In some cases, studies for the same herd have resulted in substantially different ZOI estimates. For example, five studies that estimated ZOI effects for the Central Arctic Herd reported results ranging from no ZOI to 11 km (Cronin et al. 1998, Noel et al. 2004, Cameron et al. 2005, Johnson et al. 2020, Prichard et al. 2020). Johnson and Russell (2014) found that estimates of ZOI distances varied nearly two-fold for the PCH between two decadal periods. Indeed, estimated ZOIs for the same study area can vary by year and correspond to avoiding resource development or even attraction to it (Prichard et al. 2020, Boulanger et al. 2021)[12]. Although there is a weight of evidence that caribou typically avoid human disturbances (**Appendix 9-C Literature Summary**), several studies have found either no response or apparent selection for proximity to disturbances under certain circumstances or periods (Cronin et al. 1998, Noel et al. 2004, Prichard et al. 2020, Boulanger et al. 2021).

The mechanisms associated with ZOIs for caribou surrounding human disturbances are unclear. Most studies do not demonstrate a clear mechanism associated with the spatial patterns that caribou exhibit in response to human disturbances. Mechanisms likely vary across space (e.g., across herds and vegetation types) and time (e.g., seasons and years) and may involve a combination of factors. For example, Boulanger et al. (2012) suggest that visual disturbance, noise, and dust-fall associated with a mine may collectively affect habitat selection of caribou in the area surrounding a mine. One general theory is that large prey species, like caribou, perceive anthropogenic features and/or sensory disturbances as a threat, whether real or not, and avoid those areas (Frid and Dill 2002, Boulanger et al. 2021). Given the large ZOI distances reported in some studies, for this theory to apply would require a combination of (i) direct sensory perception and (ii) learned behaviours to account for apparent ZOIs beyond sensory perception distances (Fagan et al. 2013, Boulanger et al. 2021).

When caribou avoid a ZOI, the avoidance is incomplete (i.e., indirect habitat loss is a partial effect). In all the studies listed in **Appendix 9-C** that observed a ZOI, caribou continued to use habitat within the ZOI but at a lower rate than areas outside the ZOI. Similar to the estimates of ZOI distances, the degree to which habitat use is reduced within the ZOI varies among studies. Summarizing patterns across studies is further complicated because most studies use different approaches to quantify the magnitude of effects.

Typically, the effects within a ZOI are graded, with avoidance being greatest at or adjacent to the disturbance and diminishing with distances farther away from the disturbance. Most studies report the maximum effect of the estimated ZOI (i.e., at the ZOI distance), but the average magnitude of effect over the entire ZOI is approximately half (50%) of those reported values. Johnson et al. (2020) assessed the reduced habitat use of the Central Arctic Herd within estimated ZOIs using selection ratios that compared observed versus expected use rates. The estimated ZOI was largest during calving (5 km) and lowest during periods of mosquito harassment (1 km). The authors found that habitat use was reduced to approximately a quarter (25%) of expected levels within 1 km of oil and gas infrastructure during calving

[12] These studies presume that caribou are not actually selecting distances close to human disturbances, but instead are selecting the environmental conditions near those disturbances. Thus, the preference for the environmental conditions outweighs the detriment of the disturbance.

and post-calving seasons, and by roughly a half (50%) during the mosquito season (Johnson et al. 2020). Boulanger et al. (2021) estimated the degree to which habitat use was reduced by the Bathurst Herd in relation to two mines in Northwest Territories using odds ratios, which compares the odds of caribou occurring at the disturbance footprint (0 m) versus the ZOI distance. For the years when caribou avoided the mines and the estimates were statistically significant ($P < 0.05$), the odds ratio ranged from 1.1–7.4. Polfus et al. (2011) estimated the reduction in habitat effectiveness for a woodland caribou herd in northern BC by comparing habitat models with and without human developments. They found that ZOIs around human developments (including a town, mines, and roads) resulted in an 8% decrease in high-quality winter habitat across the study area.

Baseline studies for this Project quantified local ZOI distances in the RSA using PCH telemetry data. Data from 2014, when 3D seismic exploration last occurred in the area, were inadequate to derive unbiased estimates. Instead, analyses were conducted for 2012–2021 to test whether a ZOI effect was associated with inactive (historical) linear feature disturbances, such as 2D seismic lines, winter access roads, and trails. For these linear features, ZOI estimates ranged from 2 km during winter to 4 km during late fall. However, the overall effect of ZOIs was relatively weak. The magnitude of ZOI effects corresponded to a reduced likelihood of caribou occurrences on linear feature footprints compared to distances at or beyond the estimated ZOIs—maximum reductions of 27% during winter and 45% during rut/ late fall. Since the magnitude of the effect follows a linear relationship, the average effect on caribou is approximately half (50%) of the maximum effect. Thus, the average reduction in caribou occurrence would be 13% during winter and 22% during rut/ late fall. Furthermore, including the ZOI effect in habitat models did not change how habitat was selected (i.e., little to no change in habitat-related coefficients), which suggests that caribou did not alter their habitat selection due to those linear features.

9.4.4 Movement Effects

The PCH is a wide-ranging herd. Movements by individuals occur across a gradient of scales and time periods, from daily movements (several kilometres per day) needed to meet foraging requirements and predator avoidance to seasonal movements (hundreds of kilometres) needed to meet changes in seasonal forage availability. The Project can potentially affect caribou movements by altering habitat or creating structures that physically deter movements and creating sensory disturbances that cause caribou to alter movements in response to a ZOI.

Differentiating movement effects from indirect habitat effects is difficult because both relate to caribou distribution. For example, avoidance of a road by caribou could affect habitat use and movement. Differentiating these two effects is further complicated for PCH because the caribou wander continuously and do not settle in specific areas during rut/ late fall and winter. However, because the consequence of these two effects relate to different life requisites (i.e., achieving local forage requirements versus travelling between seasonal ranges), they are considered separately in this assessment.

For this assessment, effects on movement relate specifically to the ability of caribou to travel through the Project RSA and cross through Project features (i.e., winter access roads and seismic lines). In general, caribou seem to complete seasonal migrations across resource roads or areas of anthropogenic disturbance; however, at the local scale in proximity to these sources of disturbance, there is evidence that the location and timing of movements can be altered (Panzacchi et al. 2013, Wilson et al. 2016, Boulanger

et al. 2019, Golder Associates Ltd. 2019, Prichard et al. 2020). Local effects on caribou movement can be direct, such as delayed crossings and altered movement paths and travel speeds, or indirect, such as altered behaviour and avoidance of road corridors.

Delayed crossings — Some caribou appear to delay crossing roads when encountering them. The delay time varies from minutes to hours for ground-based observational studies of local movements (Fancy 1983, Curatolo and Murphy 1986) to several days for telemetry-based studies of migration patterns (Wilson et al. 2016, Boulanger et al. 2019, Prichard et al. 2020). Using two methods of analysis, Boulanger et al. (2019) estimated average crossing delays of 5.0 and 6.2 days for caribou crossings roads at the Meadowbank Mine in Nunavut. However, that delay did not affect arrival times at calving and wintering grounds (Golder Associates Ltd. 2019). Wilson et al. (2016) classified eight of 30 caribou as 'slow crossers', which took an average of 31 days longer to cross the Red Dog Mine road than 'normal crossers'. During spring migration, reindeer in the Setesdal Austhei area delayed crossing a secondary highway by approximately five days (Panzacchi et al. 2013).

Altered movement paths — Several studies have observed instances where caribou approach an active road but alter their apparent path (assumed to be a direct crossing) to first parallel the road for some distance before crossing, resulting in a delayed crossing (Wilson et al. 2016, Russell and Gunn 2017, Boulanger et al. 2019, Prichard et al. 2020). Boulanger et al. (2019) suggested that this type of movement may represent an attempt to travel around the feature or to find a favourable crossing location. Altered movements from encounters with resource development may last several kilometres, and the distances documented in studies have varied substantially. In 2015, 12 collared PCH caribou paralleled the northwest side of the Dempster Highway for >100 km between the Richardson and Ogilvie mountains before eventually crossing the highway (**Section 6 Caribou** of **Appendix 9-A Wildlife Baseline**)[13]. In a study of migration movements across the Red Dog mine road in Alaska, eight of 30 caribou that delayed crossing the road ('slow crossers') had significantly longer migrations than normal crossers (Wilson et al. 2016). In Norway, the Setesdal Austhei reindeer changed direction to parallel a secondary, cabin-lined road for approximately five days during spring migration before eventually crossing the road (Panzacchi et al. 2013).

Altered travel speeds — Caribou sometimes travel faster in proximity to roads and resource developments. Wilson et al. (2016) observed that 'slow crossers' exhibited daily movement rates >1.5-times faster after crossing the road, potentially trying to compensate for the time associated with their delayed crossing. In the Kuparuk oilfields in Alaska, caribou from the Central Arctic Herd travelled substantially faster while crossing roads, but that effect was limited to a relatively short period (<2 hours) and distance (<1 km) associated with the actual crossing event (Prichard et al. 2020). Reindeer in the Setesdal Austhei area increased their travel speed to the highest values recorded during migration while crossing a cabin-lined road (4 km/3 hrs vs. the average of 0.5 km/3 hrs) (Panzacchi et al. 2013).

Altered behaviours — Besides direct effects on caribou movements, anthropogenic activities and development can result in changes to caribou behaviours that can indirectly affect movement. Several studies have examined the behaviour response of the Central Arctic Herd to oilfield development (Fancy 1983, Murphy and Curatolo 1987, Prichard et al. 2022). Fancy (1983) reported that activity budgets did not different between development and control areas during the insect harassment season. Many localized

[13] However, in this case, the highway was parallel to the general direction of travel by caribou.

responses to the roads, pipelines, vehicle traffic, and other structures and activities were observed, but the type and strength of the responses varied dramatically. Murphy and Curatolo (1987) found that the effect on caribou behaviour was more evident when insects were absent. They found that caribou near pipelines and roads spent more time running and less time lying than caribou in control areas, but that time spent feeding was unaffected.

Prichard et al. (2022) reported that the behavioural responses of caribou to traffic along oilfields varied with traffic level, distance to road, and group composition. Responses were stronger and more frequent on low-use versus moderate-use roads, closer to roads, and when calves were present. The frequency of moderate (standing/walking) to strong (trotting/running) behavioural reactions within 100 m of a road was much lower at the moderate-use road (20–30% of observations) than the low-use road (60–70% of observations). At distances beyond 500 m from the moderate-use road, the frequency of moderate-to-strong reactions was negligible (<10%). In all cases, caribou without calves exhibited less avoidance of roads. Prichard et al. (2022) speculated that the higher degree of reactions along the low-use road may have been a result of caribou having less opportunity to habituate to vehicle passages and/or because the traffic on the low-use road was convoyed. The convoy (a string of vehicles) may have represented a stronger stimulus than a single vehicle, which was more prevalent on the moderate-use road.

Avoiding road corridors — Although caribou regularly cross roads during migration and intra-seasonal movements, multiple studies have documented caribou avoiding ZOIs around active roads, relative to areas farther from roads (Johnson and Russell 2014, Johnson et al. 2020, Prichard et al. 2020). This response may have a greater effect on indirect habitat loss, but it can also relate to movement by reducing the permeability of road corridors within seasonal ranges (Dyer et al. 2002). In the Central Arctic Herd, the size of ZOIs associated with active roads varied from 1–5 km depending on the season (Johnson et al. 2020, Prichard et al. 2020). However, responses varied, with some caribou selecting roads and well pads for insect relief (Prichard et al. 2020). Also, an earlier study of the Central Arctic Herd found that (i) the densities of calves and all caribou were not significantly lower within 1 km of a road during pre-road and post-road periods, and (ii) that calf density was higher in the interval within1 km of the road than in the intervals 1–6 km from the road during the post-road period (Noel et al. 2004). Boulanger et al. (2019) reported ZOIs of 5–60 km associated with the Meadowbank Mine roads and found that ZOIs were larger on the pre-crossing side of the road than the post-crossing side.

The effects of human disturbances on caribou movements appear to depend on a combination of (i) the intensity of human disturbances and (ii) factors associated with caribou biology.

Traffic level, or the disturbance intensity of facilities, has a substantial influence on caribou movements and behaviours near roads and developments (Curatolo and Murphy 1986, Dau and Cameron 1986, Dyer et al. 2002, Prichard et al. 2020, 2022). Curatolo and Murphy (1986) found that traffic rates >15 vehicles/hour (360 vehicles/day) reduced crossing rates for Central Arctic Herd caribou when pipelines were adjacent to roads. In the Setesdal Austhei wild reindeer area in Norway, spring migration patterns were markedly affected by disturbance during a period of high traffic volume (>500 vehicles/day) and intense human activities. During autumn, when traffic and human activities were lower, the effect of the road was minimal (Panzacchi et al. 2013). In northeast Alberta, average traffic rates of 91–780 vehicles/day reduced non-migratory crossings by six times compared to simulated roads in late winter (Dyer et al. 2002).

Hunting from roads can increase the displacement of caribou from those roads (Ciuti et al., 2012; Paton et al., 2017; Plante et al., 2018). In a six-year study of migratory caribou in northern Quebec, the ZOIs of roads with hunting varied from 0–15 km to 0–3 km for roads without hunting (Plante et al. 2018). The exclusion of hunting along portions of the Prudhoe Bay and Kuparuk oilfield roads through the Central Arctic Herd range is generally regarded as a successful measure to mitigate the effects of the road system on caribou movements (Prichard et al. 2020).

Combining many anthropogenic features can also have a cumulative effect on caribou movements. In the Prudhoe Bay oilfields, caribou crossed elevated pipelines or roads with a similar frequency to controls (Curatolo and Murphy 1986). However, when pipelines were adjacent to active roads, there appeared to be a cumulative effect and crossing frequencies were reduced by approximately 50%. Measures to separate pipelines and roads by at least 150 m appear to mitigate that effect (Prichard et al. 2020).

Several factors associated with caribou biology also affect how resource developments affect caribou movements. Likely the strongest biological factor is that the drive for caribou to complete seasonal migrations consistently overcomes apparent concern about those features, as expressed by local scale alterations to the location and timing of movements (Curatolo and Murphy 1986, Panzacchi et al. 2013, Wilson et al. 2016, Boulanger et al. 2019, Golder Associates Ltd. 2019, Prichard et al. 2020). The season also appears to substantially affect how caribou alter their movements in response to infrastructure. Caribou are most sensitive during the calving period, cross roads less often, express stronger behavioural responses, and have larger and stronger ZOIs around roads and developments than in other seasons (Murphy and Curatolo 1987, Johnson et al. 2020, Prichard et al. 2020, 2022). Effects on movements appear to be lowest during periods of insect harassment. During the insect season, effects on movements often do not differ from control areas, and some caribou appear to select roads and gravel pads for insect relief (Fancy 1983, Curatolo and Murphy 1986, Prichard et al. 2020). Finally, the presence of calves (i.e., post-calving) typically results in elevated effects on movement compared to groups without calves (Murphy and Curatolo 1987, Stankowich 2008, Prichard et al. 2022).

The interpretation of responses of caribou movements to anthropogenic activities and developments also vary depending on the study design, analysis method, and assessment criteria used in different studies. Earlier studies of caribou movement in relation to roads limited the assessment distance to a relatively short distance (e.g., 1 km) from the roads (Fancy 1983, Curatolo and Murphy 1986). More recent studies have demonstrated that effects can occur at farther distances (i.e., >1 km). However, the magnitude of effects is typically greatest in proximity to human developments (Boulanger et al. 2019, Johnson et al. 2020, Prichard et al. 2020).

Regarding non-migratory movements, active resource roads, though regularly crossed by caribou, can be avoided relative to areas without roads. In northeastern Alberta, woodland caribou crossed roads (average 91–780 vehicles/day) six times less frequently in late winter than simulated road networks (Dyer et al. 2002). In the Central Arctic Herd, Fancy (1983) observed that caribou on experimental and control sites had similar movement rates and activity budgets. Still, many localized responses were observed to the roads, pipelines, vehicle traffic, and other structures and activities. Of the 99 groups that approached a road, pipeline, or drill site, 70.7% crossed directly, 19.2% detoured around the drill site, and 10.1% reversed direction and left the observation area.

Most studies examining the effects on caribou movements explicitly identify or implicitly assume the primary mechanism affecting movement is sensory disturbance associated with human activities. Few studies have identified physical features associated with resource developments or other human disturbances impeding caribou movement. Features like seismic lines, roads, and inactive well pads generally do not physically obstruct caribou movements. However, during winter, road maintenance creates snow banks, which, combined with sensory disturbances of traffic, can deter caribou from crossing roads (Surrendi and DeBock 1976).

Based on the cumulative evidence from the studies discussed above, several components of the Eagle Plains Project, including winter access roads and trails, seismic operations, well sites, and camps[14], can affect caribou movements. In general, the Project's effects on movement are likely to be indirect (e.g., similar to indirect habitat effects; **Section 9.4.3 Indirect Habitat**). Sensory disturbances are expected to alter caribou movements in areas adjacent to human activity. Telemetry data (2012–2022) from GPS-collared Porcupine caribou demonstrated that individuals travelled across historical exploration developments (including winter access roads, 2D seismic lines, and 3D seismic lines) when exploration operations were not active in the area (**Map 9-3** and **Section 6 Caribou** of **Appendix 9-A Wildlife Baseline**). Still, caribou may alter the location and timing/rate of movements locally as they encounter disturbances, including winter access roads and trails, seismic operations, well sites, and camps. The result could be more tortuous movements (i.e., greater and more frequent turns) through work areas due to deflections around work sites and local movement rate changes (i.e., accelerated or delayed movements).

9.4.5 Direct Mortality Effects

The Project has limited pathways to cause direct mortality to caribou. The one Project activity that has the potential to cause direct mortality to caribou is use and maintenance of winter access roads, which could result in vehicle collisions with caribou. Several studies have reported caribou mortality caused by vehicle collisions (Forman and Alexander 1998, Edmonds 1998, Kinley and Apps 2001, Hegel and Russell 2013, EDI Environmental Dynamics Inc. 2015). For some woodland caribou herds, mortality rates due to vehicle collisions can be substantial. For example, 10% of a herd in west-central Alberta was killed by vehicle collisions over two years (Edmonds 1998). However, for most herds, vehicle collisions represent a small source of herd mortality. In Yukon, an average of 18 caribou per year were killed by vehicle collisions from 2003–2014 along the Territory's highways, representing approximately 0.1% of the Territory's mountain caribou population (EDI Environmental Dynamics Inc. 2015). No collisions with caribou were reported along the Dempster Highway during this period but detection and reporting of wildlife-vehicle collisions may have been incomplete (EDI Environmental Dynamics Inc. 2015).

Often, vehicle collisions with caribou occur when individuals cross roads as part of regular movements within their range. However, caribou may be attracted to roads in winter, due to the application of road salt or due to the ease of travel on the cleared road surface, which can result in elevated mortality (Brown et al. 2000). Once on a road in winter, especially in areas with deep snow and high snow banks, ungulates will

[14] As indicated above, the Dempster Highway is an existing feature within the RSA that appears to act as a semipermeable barrier to caribou movements. Although Project activities will include travel on the Dempster Highway, that is not expected to have a meaningful change on the existing effects of the highway.

often run down the road away from approaching vehicles, instead of escaping off the road, which elevates mortality risk (Horejsi 1981, EDI Environmental Dynamics Inc. 2015).

Most studies of wildlife-vehicle collisions (including for caribou) are along high-speed highways. Vehicle collisions with wildlife are also known to occur on secondary resource roads used by forestry and the oil and gas sector, but the mortality rates on resource roads are mostly unreported. One study in Sweden observed that collision rates of moose on forestry roads were about a third (33%) of the collision rates on highways (Neumann et al. 2012). Where resource operations employ appropriate mitigation measures, vehicle collisions with wildlife can be reduced to zero or near zero levels. For example, at three coal mines in southeastern BC where bighorn sheep, elk, deer, and bears frequently occur in work areas and along project roads, a combination of mitigation measures reduced vehicle collisions to zero over a three-year reporting period: slow speed limits, stopping to give wildlife the right-of-way, and notification of wildlife occurrence location among road users via two-way radio communication (Keim et al. 2014).

9.4.6 Indirect Mortality Effects

Several studies have linked changes in habitat and land use associated with industrial resource development to elevated caribou mortality levels (Wittmer et al. 2007, DeMars and Boutin 2018, Serrouya et al. 2019). This effect is believed to be the primary threat to several subpopulations of declining woodland caribou (Environment Canada 2014, Environment and Climate Change Canada 2019). The process includes a numerical increase in predators (primarily wolves) and a functional increase in per-capita predation rates. The numerical increase in predators is due to the rise in the abundance of other ungulates, like moose and deer, in response to increases in early seral habitats associated with human activities like forestry, oil and gas development, and natural disturbances like fire. The increase in moose and deer populations supports a higher population of predators, which results in higher predation rates on caribou (Wittmer et al. 2007, Anderson et al. 2017, Serrouya et al. 2019). This process is often called *apparent competition* (i.e., moose/deer appear to be competing with caribou, but the effects on caribou are due to increased predation). The functional increase in predation rates on caribou is due to the creation of linear features (roads, trails, seismic lines, pipelines, powerlines) and, in winter, packing of snow that allows wolves to travel faster and farther, which can result in increased encounters with and predation of caribou (Latham et al. 2011a, Dickie et al. 2017, DeMars and Boutin 2018). This process is often referred to as *facilitated predation*. The effects of apparent competition and facilitated predation are often called *habitat-mediated predation effects*.

Most studies of facilitated predation and apparent competition are of woodland caribou, where wolves are the primary predator and hunting by humans is limited. In northern herds, where hunting by humans does occur, it can be a substantial source of mortality (Boulanger et al. 2011, COSEWIC 2016). Creating new access in an area can potentially elevate mortality rates on caribou due to hunting similar to facilitated predation by wolves (Bergerud et al. 1984, Festa-Bianchet et al. 2011).

The effect of habitat-mediated predation has not been directly studied in barren-ground caribou, but where barren-ground caribou occur in forested areas, there is potential for the effect to occur.

9.4.7 Energetics Effects

As mentioned in **Section 9.4.4** Movement Effects, a consequence of caribou altering their movement patterns could be increased energy expenditure. The energy balance of caribou can affect body condition (e.g., fat reserves), which in turn can affect the fecundity of female caribou (Wolfe et al. 2000, Cameron et al. 2005).

Several studies have estimated the energetic cost of anthropogenic disturbances on caribou and potential consequences to calf production. In northeast Alberta, Bradshaw et al. (1998) estimated that the energy cost to woodland caribou disturbed by oil and gas development was equivalent to 0.1–0.2 kilograms per day (kg/day) of body weight per event, and 41–137 disturbance events would be required to reduce calf productivity. Based on caribou distribution and the level of petroleum exploration activity, it was estimated that the proportion of cases where calf productivity could be affected was <10% of the scenarios they examined over five years. Luick et al. (1996) estimated the effects of disturbances from military aircraft on the energetics and fecundity of the Delta Caribou Herd in Alaska. At the highest frequency of exposure (40 days), the estimated reduction in individual fecundity was 4–5%. Given that only a small proportion of the population was likely to be exposed to overflights, and that it was unlikely that any individual would be exposed to 40 days of disturbance, the authors concluded that potential effects on the fecundity of the herd were minimal.

In terms of annual energy expenditures, for most caribou that are exposed to anthropogenic disturbances, the effects of those disturbances are small relative to natural factors that result in energy expenditure, such as snow, insect harassment, seasonal migrations, and predation attempts (Fancy 1983, Luick et al. 1996, Bradshaw et al. 1998, Wolfe et al. 2000). Although the consequences of elevated energetic output from anthropogenic disturbance can theoretically affect population productivity, there is limited evidence of that occurring. The case where that was most likely to occur is for the Central Arctic Herd, where a substantial portion of the non-winter ranges have developed oil and gas projects. Several studies have documented effects on the behaviour, movement, and distribution of that herd in response to oil and gas development. Many of the responses are predicted to have elevated energetic costs (e.g., reduced resting, fleeing response to traffic, inhibited movements). However, the Central Arctic Herd subpopulation is generally considered healthy, i.e., population size fluctuations and demographic measures since development began have been within historic ranges of the Central Arctic Herd and, more broadly, within ranges observed for other barren-ground caribou herds. During the initial years of development of the oilfields in the 1980s and 1990s, when caribou were expected to be most sensitive to development, the herd increased from about 5,000 to approximately 28,000 individuals (Cameron et al. 2005). During the mid-2010s the Central Arctic Herd declined from about 68,000 in 2010 to about 28,000 in 2017 (Lenart 2021), when energy activities were relatively consistent. These patterns suggest that the effects of oilfield development are not the primary drivers affecting the population dynamics of the herd.

The CircumArctic Rangifer Monitoring and Assessment Network has developed a Caribou Cumulative Effects model that includes a body condition component to assess the potential effects of a range of factors, including human disturbances, on the population size and composition of a caribou herd. Variations of that model have been used in several assessments of barren-ground caribou (e.g., Russell and Gunn 2019, Russell et al. 2021). That model was not used as part of this assessment because the model is intended to be run as a full life cycle model over the entire range of a herd. Given that the extent of the Project RSA is

such a small portion of the seasonal and annual ranges, and that caribou occurrences in the RSA are during seasons when the caribou are generally in good body condition and alternative habitat is available, the results of the exercise were not expected to contribute meaningfully to this assessment.

9.5 MITIGATION MEASURES

The Project has a comprehensive set of measures designed to mitigate potential effects on caribou. These include contingencies to account for unexpected behaviours of caribou and the occurrence of large numbers of caribou. The Caribou Mitigation and Monitoring Plan includes a set of monitoring programs designed to inform mitigation measures and to assess the effectiveness of measures within an adaptive management framework. A summary of key components of the mitigation and monitoring components are listed below. These components mitigate several potential adverse effects, summarized in **Table 9-7**.

- Project work will be clustered within annual work areas to minimize the area within the RSA subject to disturbance in any given season.
- All ground-based work will be limited to winter operations to avoid the development of all-season roads.
- Winter access roads, wells, and secondary camps will be located to avoid high-value caribou habitat, to the degree possible, to minimize direct and indirect effects on caribou habitat and movements.
- The winter access road network will use existing, historical roads wherever possible to minimize the length of new access that is developed. Currently, no new mainline roads are planned to branch off the Dempster Highway; however, there is a possibility that several additional access points may be needed.
    - An objective of the Project is to have as neutral an effect on human access as possible (i.e., to maintain existing access that people are accustomed to but to minimize new access that could result in incremental hunting and disturbance).
- The Project has a comprehensive set of measures to minimize the extent and effects of linear features (winter access roads and seismic lines), including the following:
    - The length and width of linear features will be minimized to the degree possible; 3D Low-Impact Seismic (LIS) lines are narrower than historic 2D seismic and contain more bends (i.e., less linear).
    - The ground vegetation layer will be protected to maintain existing vegetation composition and to hasten regeneration.
    - Sightlines and ease of movement along seismic lines will be minimized using curving line paths, narrow widths, vegetation retention, and line breaks.
- Several measures are associated with access road use and maintenance to avoid the risk of wildlife-vehicle collisions and minimize the effects on caribou movements.
- A formal caribou observation and reporting program (see Section 9.8.1.2 Caribou Observations and Reporting) and a Caribou Interaction Response Plan (see Section 9.5.10 Caribou Interaction Response Plan) have been developed to document the occurrence of caribou near work sites and respond to unanticipated caribou interactions via the development of a site-specific plan.
- The primary mitigations above are designed assuming average caribou numbers occur in or near the annual work area (i.e., several hundred caribou). Special mitigation measures and

monitoring programs are identified to respond to the potential occurrence of atypically large numbers of caribou in or near the annual work area (i.e., several thousand caribou).

Details about each mitigation and monitoring component are provided in the following sections.

Table 9-7. Mitigation Measures Relevant to Caribou and the Eagle Plains Exploration Project

Mitigation and Management Measure	Potential Adverse Effect
Avoiding High-Value Habitat	• Direct habitat effects • Indirect habitat effects • Movement effects • Energetics effects
Clustering of Work in Annual Work Areas	• Direct habitat effects • Indirect habitat effects • Movement effects • Energetics effects
Access Management	• Indirect mortality effects
Seismic Operations	• Direct habitat effects • Indirect habitat effects • Indirect mortality effects
Construction of Winter Access Roads, Well Sites, and Other Features	• Direct habitat effects • Indirect habitat effects
Access Road Use and Maintenance	• Movement effects • Direct mortality effects • Energetics effects
Aircraft Operations	• Indirect habitat effects
Pre-Work Site Surveys	• Indirect habitat effects
Early Warning System for Caribou	• Direct habitat effects • Indirect habitat effects • Movement effects • Energetics effects
Caribou Interaction and Response Plan	• Indirect habitat effects
Response to Large Numbers of Caribou	• Indirect habitat effects
Worker Training	• Indirect habitat effects
Monitoring and Adaptive Management	• Direct habitat effects • Indirect habitat effects • Movement effects • Direct mortality effects • Indirect mortality effects • Energetics effects

9.5.1 Avoiding High-Value Habitat

Quantitative habitat models were developed for the rut/ late fall and winter seasons using PCH telemetry data from 2012–2021. The models were used to map relative caribou habitat quality across the RSA. Suitable caribou habitat is widespread across the RSA, especially in the rut/ late fall season. Not all suitable habitats need to be avoided to alleviate potential effects on caribou. However, small portions of the RSA (11%) with the highest winter habitat ratings offer exceptionally high forage values (lichen) and are used much more frequently by caribou. High-value winter caribou habitat should be avoided as much as possible because (i) Project footprints that clear vegetation can reduce lichen biomass and take decades to recover, and (ii) Project activities near those areas can displace caribou in the short term.

High-value winter caribou habitat was combined with maps of other sensitive or high-quality environmental and heritage areas into an overall constraints map (**Section 3.2.2.2.6**). The constraints map was used to plan the location of Project features like winter access roads, wells, and camps to minimize the overlap of those features with high-value caribou habitat and other sensitive and high-value environmental areas. Overall, high-value winter caribou habitat comprises 11% of the RSA. The proposed mainline winter road network was developed to minimize its overlaps with high-value winter caribou habitat, and only 4% of the road system's total length overlaps with this caribou habitat.

9.5.2 Clustering of Work in Annual Work Areas

The 2,400 km² (about 40 km x 60 km) RSA constitutes a relatively small portion of the PCH rut/ late fall and winter ranges in Yukon (6.0% and 6.5%, respectively). Annual work within the RSA will be clustered in smaller areas (e.g., 400–700 km²), and only a fraction of this will experience direct disturbance), leaving the remaining portion undisturbed. Accounting for road access to the main camp along the Dempster Highway and potential ZOI buffers around the combined work area, winter access roads, and camp, approximately one-third (32%) of the RSA could be subject to sensory disturbance each year the Project is active. Clustering the annual work areas reduces the degree of overlap with the PCH seasonal ranges in Yukon to approximately 2%.

9.5.3 Access Management

The goal of the Project is to have as neutral an effect on human access as possible (i.e., to maintain existing access that people are accustomed to but to minimize new access that could result in incremental hunting and disturbance). Measures to minimize changes to access in the RSA include the following:

- No all-season roads will be constructed.
- The winter access road network will use existing, historical roads wherever possible, to minimize the length of new access that is developed.
- No new mainline roads will be created off the Dempster Highway.
- At the end of the Project a combination of ditches, berms, debris piles and gates will be established to limit access to the mainline road network. The methods used at each site will be tailored to local site conditions.
- Access onto and along seismic lines will be limited using a combination of measures:

- Narrow widths and meandering paths will minimize sightlines and hinder all-terrain vehicle (ATV) travel. All seismic lines will be <3 m wide.
- The ground vegetation layer (mosses, lichens, and forbs), including low shrubs and tree seedlings, will be protected to hasten tree and shrub regeneration.
- Access onto seismic lines from the Dempster Highway and mainline winter access roads will be limited by (i) terminating lines ≥10 m short of the road (where operationally feasible) and (ii) where the line must cross the road by creating a sharp dogleg in the line where it crosses the line, to reduce the visibility of the line from the road[15].

- While the Project is active, the general public's access to the annual work area will be restricted for safety reasons.
  - Special access for First Nations land users into the annual work area will be accommodated on a case-by-case basis so long as appropriate safety conditions can be met by all parties (e.g., no use of firearms within 2 km of roads and work sites, use of two-way radios along roads, avoidance of active work sites).

9.5.4 Seismic Operations

Several studies have documented negative effects of linear features, especially seismic lines, on caribou and caribou habitat (James and Stuart-Smith 2000, Dyer et al. 2001, Latham et al. 2011a). In all those studies, seismic lines were predominantly older 'conventional' lines ≥5 m wide, mostly long and straight, and involved the removal of ground vegetation layer and the disturbance of topsoil via a bulldozer. Conventional lines also created windrows of debris that could potentially have trapped animals. Contemporary seismic operations, often referred to as 'low-impact seismic' (LIS), use different approaches and equipment that inherently reduce the degree of effects associated with the lines created (e.g., no creation of windrows). For example, LIS lines are mostly ≤3 m wide. The path of the LIS line includes frequent bends to reduce sightlines and to hinder travel of humans and predators. The ground vegetation layers are maintained and protected to enable faster regeneration, which limits the line's effectiveness for facilitating predation. Specific mitigation measures can further reduce effects beyond those that inherently result from LIS. Mitigation measures associated with seismic operations for this Project will include the following:

- Seismic lines will use narrow widths and meandering paths to minimize sightlines and hinder human travel (e.g., ATV) and predators.
  - Line widths will vary by line type:

Seismic Line Type	Size or Width	Percent of Total Seismic
• 3D Receiver Lines	• 1.75 m	• Approx. 40%
• 3D Source Lines	• 2.75 m	• Approx. 40%
• 2D Lines	• 2.75 m	• Approx. 20%

[15] During baseline studies, only four of 74 3D LIS lines from the 2013/14 program that crossed the Dempster Highway were detected during a driving survey along the highway **(Appendix 9-B Linear Feature Study**).

    - The tortuosity degree (i.e., angles, length of bends, and distance of offset from the theoretical centerline) will also vary to account for site factors, including topography and vegetation structure.
        - The target for the average sightline distance along seismic lines is 50 m for source and receiver lines, which corresponds to average sightline distances in undisturbed vegetation[16] in Eagle Plains (**Appendix 9-B**), and 75 m for combination lines, which require reduced tortuosity to permit equipment travel along them.
        - Generally, the meanders in seismic lines in the field will result in the line being offset 10–20 m from the theoretical centerline if the line were straight.
        - To hinder human and predator travel, the angle of the bends in the lines will be as sharp as possible, within the operating constraints of the mulcher equipment. Most angles will be 30–45 degrees. Sharp dogleg bends with winter access roads and other seismic lines will be established at most junctions.
- Vegetation clearing will be limited to trees and tall shrubs. The ground vegetation layer (mosses, lichens, and forbs), including low shrubs and tree seedlings, will be maintained by conducting clearing using low ground pressure mulchers in the winter when the ground is frozen and a minimum packed snow depth of 10 centimetres (cm) is present. Retaining the ground vegetation maintains existing vegetation composition and hastens vegetation regeneration (i.e., compared to disturbances, such as fire, where most of the existing vegetation is destroyed and primary succession is initiated on exposed soil).
    - The extent of trees and shrubs that will be cleared will be minimized by having the operator adjust the exact location of the line in the field to follow natural openings and vegetation gaps.
    - Wherever possible shrubs and tree saplings ≤2 m will be pushed over, instead of being cut.
- Access onto seismic lines from the Dempster Highway and mainline winter access roads will be limited by (i) terminating lines ≥10 m short of the road (where operationally feasible) and (ii) where the line must cross the road, by creating a sharp dogleg in the line where it crosses the line, to reduce the visibility of the line from the road.[17]

The primary method of reducing direct habitat effects on caribou is to maintain ground vegetation and lichen cover. The result of this mitigation is two-fold. First, existing lichen cover is expected to persist, at least initially, after vegetation clearing. On lines >3 m and other types of openings, as vegetation regenerates, lichen is expected to be substantially reduced as forbs and shrubs overgrow the sites, due to increased light exposure (Lee and Boutin 2006, Dabros et al. 2022). However, on seismic lines ≤3 m, the density of forb and shrub regeneration is expected to be limited and lichen is expected to persist, though potentially at reduced levels (Golder Associates 2016, Dabros et al. 2017, EDI unpubl. data) (**Photo 9-1**). For lines

[16] Average sightline distances along the 3D LIS lines created in 2013/14 were: 60 m, 76 m and 106 m for receiver, source, and combination lines, respectively, compared to an average distance of 46 m in adjacent undisturbed vegetation (**Appendix 9-B**).
[17] During baseline studies, only 4 of 74 3D LIS lines from the 2013/14 program that crossed the Dempster Highway were detected during a driving survey along the highway (**Appendix 9-B**)

≤3 m wide, the opening is typically not large enough to result in light exposure or competition from other vegetation types that elevate forb and shrub development to the point that lichens are replaced. Instead of following a transitional successional pathway of vegetation dominated by forbs, then shrubs, then trees, vegetation regeneration on narrow lines appears to follow more of a gap-phase dynamic pathway, where a combination of forbs, shrubs, and trees associated with the adjacent forest community regenerate concurrently. The extent of moss and lichen cover is maintained (Golder Associates 2016, Dabros et al. 2017, EDI unpubl. data). It is important to note that approximately 47% of the RSA has already been disturbed by fires <40-years old, which has likely already reduced lichen quantities by substantial amounts.

The second outcome of this mitigation is that it reduces the regeneration time for the site to recover to its pre-disturbance condition. Recovery time is expected to be fastest for lines ≤3 m wide. However, even on lines >3 m wide, where lichen cover is substantially reduced and the vegetation undergoes more of a traditional succession trajectory, regeneration times can be one or two decades faster than on sites where the original ground vegetation is removed. Primary succession begins on bare soil (Golder Associates 2016). For example, seedling trees and shrubs retained on the lines provide a much earlier start for those vegetation types than sites revegetating from bare soil (Golder Associates 2016).

9.5.5 Construction of Winter Access Roads, Well Sites, and Other Features

In addition to seismic operations, the Project will require the development of winter access roads, well sites, the airstrip, and secondary camps. The following measures will be applied to mitigate the potential effects on caribou:

- The location of all winter access roads, well sites, and secondary camps will be assessed relative to high-value winter caribou habitat within the constraints mapping and will be avoided as much as operationally feasible.
- The total extent of Project features will be minimized as much as possible while meeting operational requirements to minimize direct effects on caribou habitat. The maximum sizes of Project features are:

Feature Type	Size or Width
• Mainline Winter Access Roads	• 8–10 m (two-lane) • 16–20 m (pullouts, every 5 km)
• Well Site Access (Spur) Roads	• 10 m
• Well Sites	• 1.44 ha
• Airstrip	• 6.8 ha

- All features will be developed to ‘winter use’ standards, protecting the ground vegetation layer and minimizing the severity and persistence of direct effects on caribou habitat.
    - Vegetation clearing will be limited to trees and tall shrubs. The ground vegetation layer (mosses, lichens, and forbs), including low shrubs and tree seedlings, will be maintained by conducting clearing using low ground pressure mulchers in the winter, when the ground is frozen, and a minimum snowpack of 10 cm is present. Retaining the ground vegetation maintains existing vegetation composition and hastens vegetation regeneration.

    - For winter access roads and the airstrip, the ground vegetation and soil/peat substrate will be protected by creating a packed and frozen surface of snow/ice at a minimum 10 cm thickness. For well sites and the camp, the ground will be protected using a combination of rig mats and packed and frozen snow.
- Before initiation of work at new sites, a Pre-Work Site Survey (**Section 9.5.8 Pre-Work Site Surveys**) will be conducted.

9.5.6 Access Road Use and Maintenance

The following measures are designed to mitigate the risk of vehicle collisions and effects of access road use on wildlife movements:

- Speed limits will follow those posted for the Dempster Highway (on average, 90 kilometres per hour [km/h]), adjusted as needed for weather and road conditions, and 40 km/h along all winter access roads for all Project vehicles.
- During winter, the following measures will apply to managing snowbanks (i.e., to minimize hindrance to animals crossing them):
    - Maintain snowbanks at heights of less than 1 m above base snowpack depth.
    - Where snowbanks exceed 1 m in height above base snowpack depth (which could present a visual obstruction [Rescan Environmental Services Ltd. 2011]), create regular breaks (at least every 1,000 m) to facilitate easier animal crossings and as escape routes (run-outs) off the access road.
        - Create matched breaks in the snowbanks on either side of the access road that animals can use to cross.
    - On corners, create run-outs following the line of travel from each direction along the access road that provide obvious alternative routes for animals to use, instead of following the access road.
- Caribou (and other wildlife) on or near the access road will always have the right-of-way. Stop when wildlife is observed on or beside the access road, stopping as far back from the animals as possible, and allow the wildlife to cross at their discretion. Once the animals have crossed or retreated from the access road, wait 5 minutes, then resume travel at 10 km/h for 200 m past the point the animals were observed before resuming normal travel speed. If wildlife stays on the access road margin for more than 10 minutes, resume travel and pass the animals at 10 km/h or less.
- When caribou and other ungulates are on an access road, they will sometimes run down the access road away from a vehicle instead of moving off the access road. If this happens, stop, and wait at least 10 minutes for the animal to move off the access road. If the animal remains on the access road, drive forward at 10 km/h, then stop again when the animal begins to run away. Wait 2 minutes and repeat this procedure. If the animal still does not leave the access road, wait 10 minutes, and repeat the procedure, alternating with a 2- and 10-minute stop between driving attempts.
- Do not exit the vehicle to chase, catch, divert, follow, photograph, or otherwise harass wildlife.
- Use two-way radio communication and communicate the location of any wildlife observed along Project access roads to other road users on the radio.

- Fill-out a wildlife observation for all caribou observed along an access road and include the km marker location. Also include the number of caribou and their initial behaviour and the driving measures employed (e.g., stopped and waited for the caribou to move away) the response of the caribou.
- Report any caribou observations daily to the Environmental Monitor on site.

9.5.7 Aircraft Operations

Aircraft operations may include fixed-wing flights into the local airstrip to transport crews and supplies as well as local crew shuttles via helicopter.

9.5.7.1 Fixed-Wing Flights — Crew and Supply Flights

Crew and supply flights into the Chance Airstrip have low potential for collisions with caribou when landing and taking off. Pilots will conduct a low-elevation fly-by before landing to avoid aircraft collisions with caribou and other wildlife during landing to scan for wildlife on or adjacent to the airstrip.

9.5.7.2 Helicopter Flights

Most local travel between work sites and camps will be via ground transportation. However, a helicopter may be required to shuttle crews and supplies from the main camp to remote work areas. When this occurs, there will be multiple flights per day to deliver and retrieve crews. Helicopter operations will occur primarily during summer and will follow guidelines outlined in *Flying in Caribou Country* (Government of Yukon 2010). Key mitigations include the following.

- At the pilot's discretion for safety, all flights must maintain an altitude of at least 400 m above the ground.
- If/when caribou are spotted, the pilot will adjust the flight route to avoid flying over the animals, providing a 1,000 m horizontal clearance distance. The pilot will not fly toward, follow, fly over, hover over or near, circle, or land near any animals.
- If caribou persist at specific locations for an extended period (i.e., more than three days), flight routes will be developed to avoid those areas, providing a 1,000 m horizontal clearance distance.
- If large numbers of caribou occur in the area, the minimum flight altitude will be increased to 500 m and flight routes will be developed to avoid flying over high-value caribou habitat.
- Helicopter pilots will record and report all wildlife observations daily to Chance.

9.5.8 Pre-Work Site Surveys

Before work starts, pre-work site surveys are conducted to assess the presence of caribou (and other wildlife), wildlife features, and high-value habitat near proposed work sites.

Pre-work site surveys will be conducted primarily via ground surveys; drones may be considered if light and other logistical considerations allow for it. The primary type of caribou information assessed during the survey is the intensity of current caribou use within and near the proposed work area. This can include the actual presence of caribou and concentrations of caribou signs, including tracks, pellets, feeding sign, and beds. The survey route will consist of meandering transects within and adjacent to the work area.

Outside of when 'large numbers' of caribou are present, pre-work site surveys will be conducted for a subset of work locations where caribou are more likely to occur and for Project activities with a higher intensity of disturbance. Specifically, pre-work surveys will be conducted to construct winter access roads, well sites, the airstrip, and secondary camps where those sites overlap with or are within 200 m of high-value seasonal caribou habitat. Pre-work surveys will not be conducted in low-value caribou habitat areas (e.g., recent burns) because the value of those areas to caribou is low or for seismic operations because the disturbances associated with seismic work are less intense and more transitory. If large numbers of caribou are present, the scope of coverage of pre-work surveys should be expanded to include high-value caribou habitat associated with seismic operations and all areas associated with the construction of winter access roads, well sites, the airstrip, and secondary camps.

Pre-work site surveys should occur within 1–2 days of the start of work because caribou can travel several kilometres in a day. A series of surveys will be required before the development for access road construction or other developments where the location advances over time. Surveys will be conducted by personnel knowledgeable of caribou sign and habitat use, either by or under the direction of the Environmental Monitors or Project Biologists.

Results of pre-work site surveys will be used to inform modifications to the timing or location/route of work areas to minimize effects on caribou. In most situations, the most practical mitigation measure is to pause work until the caribou have moved away from the area, typically within 1–2 days. For example, if crews observe caribou during line construction, all nearby personnel would be notified by radio; a plan would be implemented to stop construction or change course (depending on the distance to caribou). If caribou persist in an area for a longer period, mitigations may require adjusting the work location/route to avoid the area or moving to an alternative work area until the caribou have moved away.

9.5.9 Early Warning System for Caribou

Discussion with the PCTC and PCMB led to a broad consensus among members to establish an early warning system for caribou presence in the RSA. The primary objective would be to forecast the potential timing and magnitude of Project interaction with Porcupine caribou based on data (surveys, GPS locations) collected and reported by the PCTC. This system would require regular, direct communication between Chance and the PCTC before the commencement of work in early winter and throughout active exploration periods during the winter. The PCTC has committed to regular communications and updates as more Porcupine caribou are tracked and observed moving toward the RSA. Once the PCTC has identified the possibility of caribou presence in the RSA, Chance commits to reconsidering the location of a given year's seismic program, and discussing the need for further monitoring that does not conflict with other surveys that may be implemented by the PCTC, Yukon Government, or other interested parties.

9.5.10 Caribou Interaction Response Plan

Pre-disturbance assessments and associated measures are designed to avoid disturbing/displacing caribou by initiating work at new locations. However, there could be situations where caribou move near an active work site. As mentioned above, the mostly likely response by caribou to Project activities is that they will avoid work areas due to sensory disturbance (Frid and Dill 2002, Stankowich 2008). If they are avoided, no further mitigations are required (i.e., because there will be no further interactions between the Project

and caribou). However, caribou may move near seismic operations, well site operations, or camps out of curiosity or if they have evaluated the activity occurring there and decided it is not a threat (i.e., habituate to the activity) (e.g., Cronin et al. 2000, Noel et al. 2004, Haskell et al. 2006, Haskell and Ballard 2008).

In general, the occurrence of caribou in proximity to Project activities (e.g., near a drilling rig or camp) is not a cause for immediate responses.

1. Most Project activities, such as seismic line development, have significant sensory disturbances (including visual, auditory, and olfactory) that caribou normally detect from several hundred metres away. Like other prey species, caribou are likely to treat a source of anthropogenic disturbance similar to a predation risk and avoid the area (Frid and Dill 2002). If a caribou decides to occur in proximity to a work site (i.e., within human sight distances), it means the individual has decided to investigate it further or determined that is does not pose an immediate threat (see Stankowich 2008 for a review of varied responses of ungulates to disturbance stimuli).
2. Most Project activities do not pose a mechanism to negatively affect caribou (other than the sensory disturbance the caribou has decided not to avoid). Given these factors, the initial response of a work crew to the observation of caribou will be to continue normal operations and intermittently monitor the location and behaviour of the caribou**.** Stopping work can cause more disturbance to the caribou (i.e., more disturbance than continuing normal operations) because it represents a change in the behaviour of the work crew in response to the presence of the caribou (Stankowich 2008).

If caribou are observed during Project activities (other than travelling along winter access roads and trails), the Caribou Interaction Response Plan, outlined in **Table 9-8**, is to be followed. For any interactions with caribou along winter access roads and trails, refer to **Section 9.5.6 Access Road Use and Maintenance**.

Table 9-8. The Caribou Interaction Response Plan. This Plan is Meant to be Followed if Caribou Approach an Active Work Area

Level	Trigger	Action/Response
Level 1	Caribou are first observed.	• Record as a Wildlife Observation. • Report the observation to the Environmental Monitor. o The Environmental Monitor will pass the location on to other workers in the vicinity, including helicopter pilots, to employ mitigation measures appropriate to their work activity. • Continue regular work activities. • Monitor caribou location and activity every 30 minutes while they are within sight of the work site. • Report details of the observations to the Environmental Representative at the end of the shift, who will forward the observation to Project Biologist for an initial assessment.
Level 2	Caribou persist near a work area for more than one day.	• The work crew will report the continued presence to the Environmental Monitor via radio, who will notify the Project Biologist. • The work crew will continue normal operations and monitoring for the remainder of the shift, as per Level 1. • The Project Biologist will direct a site assessment by the Environmental Monitor to collect additional information about the caribou occurrence, including the proximity of caribou to the work site and the behaviour of caribou,

Level	Trigger	Action/Response
		to ascertain the reason for the caribou persisting in the area and whether there is any interaction occurring between the work activity and the caribou.[1] • Based on the results of the assessment, a site-specific mitigation plan will be developed. [2]

1. If caribou persist within sight of a work area for more than one day, a Project Biologist will be involved to conduct a more detailed assessment of the situation. This will normally involve a site assessment to collect additional information to assess the reason for the occurrence of caribou in the area, the effects the drilling activity could have on the caribou, and, if appropriate, to develop site-specific mitigations. The Environmental Monitor will conduct the site assessment under the guidance of the Project Biologist remotely. The evaluation could vary depending on the details of the initial report but will generally involve the Environmental Monitor, observing the caribou intermittently over several hours to determine the locations the caribou are using and their behaviours (including behaviours associated with agitation and elevated vigilance). If the caribou occur intermittently in the area, the sites they occurred at will be investigated when they are not present, to look for signs of foraging, bedding, and other behaviours that could explain their presence at those sites. A site-specific management plan will be developed based on the assessment findings.
2. Depending on site conditions and caribou behaviour, a range of site-specific plans may be appropriate. However, two basic scenarios are most likely. (1) If caribou persist in the area but exhibit signs of agitation or elevated vigilance, the work site would be temporally shut down while caribou are present. This typically includes a no-disturbance buffer of 500 m or line-of-sight, whichever is greater. (2) If caribou persist in the area but do not exhibit signs of agitation or elevated vigilance (i.e., the caribou exhibit signs of habituation), work activities would continue with regular monitoring of the situation.

9.5.11 Response to Large Numbers of Caribou

Typically, in rut/ late fall and winter, the PCH is widely dispersed in small and medium-sized groups across its seasonal ranges. If the PCH were spaced evenly across the winter range, approximately 1,500 caribou would be expected to occur within an annual work area at any given time (based on the approximate 2% size of annual work areas relative to the size of the winter range in Yukon and the last population estimate of the herd). The actual number of caribou is expected to vary substantially within a typical year based on the dynamics of caribou movements and aggregations (e.g., perhaps 0.5–5% of the herd might occur at a given time). Under this typical distribution pattern, there will likely be regular caribou travelling through and foraging in the annual work area, even if some animals avoid the area due to sensory disturbances from the Project. In years with this typical distribution pattern, the mitigation measures outlined above, combined with caribou observation monitoring and implementation of site-specific mitigation plans as necessary, are expected to avoid any effects at the population level. For example, only 2% of the herd would be affected at a given time, and the effects would primarily be displacement of the herd to alternative habitat and travel routes outside the annual work area.

However, in some years, the distribution of PCH can be more concentrated. For example, deep snow in some parts of the winter range can make those areas less available to the herd, resulting in higher, concentrated use in other parts of the range (Russell et al. 1993). Although Eagle Plains is avoided in more years than selected, caribou concentrations can occur in Eagle Plains in some years for reasons such as the prevalence of deeper snowpacks there than in other parts of the winter range. If concentrated use of Eagle Plains were to occur when the Project was active, additional monitoring and mitigations may be warranted to minimize effects (i.e., because more caribou could be exposed to effects, possibly for a longer period, and because alternative habitat outside the RSA might be limited).

9.5.11.1 Monitoring Caribou Numbers

Determining the number and distribution of caribou will include a multi-staged approach. The first stage will consist of semi-weekly monitoring GPS collar data as a coarse index of potential caribou. The initial trigger of a 'large number' of caribou will be if ≥10% of the collared caribou in Canada occur within the annual work area plus a 20-km buffer[18].

The second monitoring stage will consist of aerial surveys to determine the number and distribution of caribou across the annual work area. Nearby control areas will also be surveyed to assess differences in the numbers and distribution of caribou within the annual work area relative to unaffected areas. Ultimately, this comparison will help to determine potential effects and support better-informed mitigations.

The third monitoring stage will consist of local effects monitoring studies to determine and characterize the effects of Project activities on caribou to support active adaptive management. The specific types of studies that are implemented will depend on the types of Project activities that are ongoing at the time, the number and distribution of caribou that are present (based on stage 1 and 2 surveys), and (iii) qualitative information about the types of Project-caribou interactions that are reported from worker observations, wildlife monitors, and caribou interaction investigations. Candidate studies include:

- Ground or aerial track surveys to estimate ZOI effects around different types of work sites (e.g., active well sites, 3D seismic areas, or mainline winter access roads);
- Ground or aerial track surveys to examine the effects of linear features on caribou movements (e.g., rates of turn-backs or deflections along paths near access roads); and,
- Near real-time analysis of GPS telemetry data in relation to active work sites to assess potential ZOI effects and effects on movement.

Effects monitoring studies will be initiated within one week of the occurrence of 'large numbers of caribou' and will be designed to provide actionable results within a week of a study's start. Site-specific measures will be developed based on the study's results, similar to the Caribou Interaction Response Program outcomes. For example, if a snow track study observed high rates of turn-backs or deflections of caribou along a mainline winter access road, potential mitigations could include (a) further reducing the snowbank height and (b) reducing traffic-passage rates by limiting access road use to convoys (a string of vehicles) during specific times of the day.

9.5.11.2 Mitigation Measures if a Large Number of Caribou are Present

If a 'large number' of caribou are present in the annual work area, the following measures will be implemented.

- Work at existing sites can continue, but work at new sites (i.e., requiring the construction of new winter access roads or plowing inactive rods to access the new areas) will be postponed until the large number of caribou has moved out of the annual work area.
- If the 'large number' of caribou persist in the annual work area for more than 10 days, a 'temporary constrained work area plan' will be developed. Development of the plan will consider

[18] The 20 km buffer is to account for animals that have potential to travel into the annual work area between collar checks.

(i) caribou habitat suitability mapping (i.e., to minimize overlap with suitable habitat), (ii) caribou occurrence data (i.e., from GPS collars, aerial surveys, and worker observations), and (iii) the results of effects monitoring studies. This plan will include the following.

  - Reducing the extent of operations to less than half (<50%) of the original annual work area.
  - Reducing the number and length of mainline winter access roads that are maintained and used to the minimum that is operationally feasible.
  - Restricting winter access road travel to convoys during limited operation windows (e.g., three 2-hour travel times at 6 am, 12 pm, and 6 pm) to limit the effects of access road use on caribou movements.

- As the results of the stage three effects monitoring studies become available, they will be reviewed semi-weekly. As warranted, the results will refine general mitigation measures and the constrained work area plan. This could include more restrictive measures, including up to the temporary shutdown of all Project activities or the relaxation of measures if caribou demonstrate tolerance or habituation to Project activities.

9.5.12 Worker Training

All Project personnel will receive basic training about wildlife mitigation measures and reporting wildlife sightings as part of their initial orientation. Training will be completed once a year for each person working on site, including contractors. The training aims to familiarize all personnel with the Company's policies and procedures related to wildlife, including caribou. The training will emphasize workers' responsibilities for avoiding or minimizing the effects of Project work on wildlife and wildlife habitat, including disruption and disturbance to caribou. The training will go through the specific mitigation measures outlined in the Caribou Mitigation and Monitoring Plan, that apply to each worker's position. Project personnel will be trained to identify focal wildlife and wildlife features, such as dens or nests, and report wildlife observations using a standard wildlife observation form. They will also be trained about wildlife encounters or chance finds of wildlife features that require special responses, such as stopping work until the Environmental Monitor, or the Project Biologist has assessed the area. During seismic line clearing, daily tailgate meetings will be held and any caribou sightings will be communicated to all personnel; reminders will be provided to report all observations.

The following topics will be included in the wildlife training session:

- introduction and overview of the Caribou Mitigation and Monitoring Plan;
- identification of wildlife and wildlife features, with emphasis on caribou;
- wildlife timing windows;
- roles and responsibilities of the Project Manager, Environmental Monitor, Project Biologist, and on-site personnel;
- when and how to contact the Environmental Monitor and Project Biologist;
- procedures for reporting observations of wildlife and wildlife features;
- pre-disturbance survey requirements;
- how and when stop work procedures occur; and,
- bear safety.

In addition to the general orientation for all personnel, the Project Biologist will provide more detailed training to the Environmental Monitor about specific tasks related to caribou, such as protocols for monitoring caribou if they occur in proximity to any of the Project operations (see **Section 9.5.9 Early Warning System for Caribou**).

9.6 EFFECTS CHARACTERIZATION

9.6.1 Approach

Characterizing the residual effects on caribou considers the Project's potential effects (including existing development and conditions) and the mitigations used to minimize those effects. The spatial boundaries of assessment include multiple scales that are specific to caribou: (1) the RSA, (2) the Eagle Plains ecoregion, and (3) the extent of the rut/ late fall and winter seasonal ranges for the PCH (**see Section 3.3.1.4.1 *Spatial Boundaries*, Table 3-3**). These scales of analysis correspond to the Caribou Study Areas (CSA) (see **Table 3-3**). The information and inferences presented in this section are based on the studies and literature discussed in **Section 9.4 Project Interactions and Potential Effects**.

Residual effects on caribou have each been characterized in terms of magnitude, likelihood, geographic extent, duration, timing, frequency, reversibility, context, and confidence. Each of these terms are defined and described for caribou in **Table 9-9**. For example, residual effects from the Project are classified into four levels of magnitude based on the percent change in an assessment indicator: Negligible (<1%), Low (1–10%), Moderate (11–35%), and High (>35%). These magnitude ratings were established by interpreting the relationship between habitat disturbance and population viability, as outlined for boreal caribou in *Scientific Assessment to Inform the Identification of Critical Habitat for Woodland Caribou, Boreal Population, in Canada* (refer to Table 9 in Environment Canada 2011). In that report, Environment and Climate Change Canada (ECCC) identified population risk levels associated with different amounts of total disturbances (hereafter referred to as 'ECCC-defined disturbance')[19]: very low (<10%), low (10–35%), moderate (35–45%), high (34–75%), and very high (>75%). To be cautious in this assessment, anything beyond 35% total disturbance is considered a high-magnitude habitat effect. Furthermore, in the absence of more relevant information for barren-ground caribou or other types of residual effects (e.g., mortality and movement), the ratings used to classify the magnitude of habitat effects was also used for all other residual effects. Assessment and characterization of residual effects are provided in **Sections 9.6.2** through **9.6.7**.

The significance of all residuals effects is assessed in combination to determine the overall affect of the Project on caribou after mitigations are applied (see **Section 9.7 Significance**).

[19] The total amount of disturbance refers to the area of anthropogenic footprints, plus a 500 m buffer around those footprints, and natural disturbances such as wildfires.

Table 9-9. Definitions of Effects Criteria Classifications for the Assessment of Caribou in the Eagle Plains Exploration Project

Criterion		Rating	Definition
Magnitude		Negligible	There will be no measurable change from existing conditions. **This corresponds to a <1% change in an assessment indicator.**
		Low	The residual effect will be a slight, but measurable change from existing conditions. **This corresponds to a 1–10% change in an assessment indicator.**
		Moderate	The residual effect will be a measurable change from existing conditions but will not affect the viability of Porcupine caribou. **This corresponds to a 11–35% change in an assessment indicator.**
		High	The residual effect will be a substantial, measurable change from existing conditions that may affect the viability of Porcupine caribou. **This corresponds to a >35% change in an assessment indicator.**
Likelihood		Unlikely	No residual effect is expected, but a residual effect is not impossible.
		Possible	A residual effect may occur but is not likely.
		Probable	A residual effect is likely to occur, but it is not certain.
		Certain	A residual effect will occur.
Geographic Extent		Maximum disturbance footprint	The residual effect will be confined to the maximum disturbance footprint.
		Region	The residual effect will be confined to the regional study area.
		Ecoregion	The residual effect will extend beyond the regional study area but will be confined within the Eagle Plains ecoregion.
		Seasonal Range	The residual effect will extend to the rut/ late fall and winter seasonal ranges.
Duration, Frequency and Timing	Duration	Short-term	The residual effect will occur for less than one year.
		Medium-term	The residual effect will occur for greater than one year and up to the life of the Project.
		Long-term	The residual effect will extend beyond the life of the Project.
		Permanent	The residual effect is predicted to be permanent and thus unlikely to recover to existing conditions.
	Frequency	Occasional	The residual effect will occur rarely (once or a few times over the life of the Project).
		Irregular	The residual effect will occur more than a few times but not at regular intervals. The effect will be dependent on the sporadic interactions between caribou and the Project.
		Periodic	The residual effect will occur consistently at regular intervals or associated with temporal events (e.g., during spring freshet, low flows, growing season).

Criterion		Rating	Definition
		Continuous	The residual effect will occur continuously.
	Timing	Year-round	The residual effect will occur year-round.
		Seasonal	The residual effect will be confined to a portion of the year.
Reversibility		Reversible	The residual effect is predicted to be reversible within a clearly defined period.
		Irreversible	The residual effect is predicted to be irreversible.

9.6.2 Residual Direct Habitat Effects

The Project is expected to have direct habitat effects on caribou via vegetation clearing associated with the development of seismic lines, winter access roads, well sites, and secondary camps. Vegetation clearing is expected to reduce the amount of 'selected' (moderate and high quality) habitats by caribou. To assess the residual direct habitat effects to caribou, several aspects of the Project's spatial extent and development pattern are considered:

- The extent of direct habitat effects is expected to be limited to a small portion of the available habitat within the RSA.
- Affected areas are expected to occur at narrow linear features and small openings <4 ha.
- Effects are expected to be widely dispersed across the RSA.
- Lichen cover is expected to be initially maintained at most sites. As taller vegetation regenerates on affected sites, lichen is expected to persist on seismic lines ≤3 m. On lines >3 m, and other types of openings, lichen is expected to be substantially reduced as forbs and shrubs overgrow the sites due to increased light exposure. However, approximately 47% of the RSA has already been disturbed by fires <40-years old, which has likely already reduced lichen quantities by substantial amounts.

Direct habitat effects were assessed by quantifying the extent of overlap of exiting features and Project features with rut/ late fall and winter caribou habitat model outputs. Calculations of direct habitat effects considered only moderate and high rated habitat, which are 'selected' by Porcupine caribou **Section 6 Caribou** of **Appendix 9-A Wildlife Baseline**), and excluding low and very low rated habitat. The age of existing features varies from the late 1950s to 2015, and the vegetation on those features has regenerated to varying degrees depending on the time since disturbance, type of disturbance, and site conditions (**EDI Linear Feature Baseline – Appendix 9-B**). However, since caribou habitat quality depends largely on the biomass of ground lichen, and because lichen takes several decades to regenerate, all existing features, except 3D LIS lines, were assumed to have nil habitat value for caribou. For 3D LIS lines (existing and proposed), lichen persists after the lines are cut, and a 50% downgrade was applied (e.g., if 100 ha of suitable habitat was affected by 3D LIS lines, the effect would be 50 ha).

Direct habitat effects will largely be limited to the RSA, specifically confined to the maximum disturbance footprint. A small amount of habitat could be affected along winter access roads to water withdrawal sites outside the RSA. The extent of direct habitat effects from the Project will be small: 2% for rut/ late fall and winter habitats in the RSA, and 0.2% for rut/ late fall and winter habitats at the Eagle Plains ecoregion scale (**Table 9-10**).

Table 9-10. Direct Habitat Effects from Existing and Project-Related Disturbances on 'Selected' Caribou Habitat During Rut/ Late Fall and Winter in the Project Regional Study Area (2,387 km²) and the Eagle Plains Ecoregion (21,984 km²)[1]

Effects Category	Rut and Late Fall		Winter	
	RSA	Ecoregion	RSA	Ecoregion
Existing (Baseline), Direct Effects	8.5 km² (0.9%)	32.3 km² (0.4%)	3.7 km² (0.6%)	19.6 km² (0.4%)
Project Wellsite Scenarios (n = 10), Direct Effects	18.5–18.8 km² (1.9–2.0%)	18.7–19.0 km² (0.2%)	12.4–12.6 km² (2.0%)	12.6–12.7 km² (0.2%)
Total Direct Effects on 'Selected' Habitat	27.0–27.3 km² (2.8%)	51.0–51.3 km² (0.6%)	16.1–16.2 km² (2.6%)	32.1–32.2 km² (0.6%)
Selected' Habitat Unaffected by Disturbance	937.8–938.2 km² (97.2%)	8,348.7– 8,349.0 km² (99.4%)	608.1–608.2 km² (96.2%)	5,422.9–5,423.1 km² (99.4%)
Total 'Selected' Habitat	965.1 km² (100.0%)	8,400.0 km² (100.0%)	632.4 km² (100.0%)	5,455.2 km² (100.0%)

[1] The Project's effects are calculated based on the lifetime of the exploration program.

* Percentages are relative to the total amount of 'selected' caribou habitat during rut/ late fall and winter seasons.

A summary of the characterization of residual direct habitat effects on caribou is provided in **Table 9-11.** Two aspects of the Project limit the magnitude of direct habitat effects: (i) protection of ground vegetation by clearing during the winter and (ii) the size and shape of Project features. The combination of maintaining ground vegetation and the Project's spatial extent and development pattern has two primary consequences on caribou habitat:

6. The shape, size, and distribution of Project footprints is expected to affect a relatively small area of habitat. This effected habitat will likely be dispersed across suitable habitat areas within the RSA. As a result, the distribution of suitable caribou habitat across the RSA will be largely maintained, with a relatively small reduction in the total amount of habitat spread out across all suitable habitat areas. This pattern differs from natural disturbances, like wildfires, and some types of human developments, like mines, which result in more contiguous disturbances that can affect habitat distribution at stand and sub-watershed scales.
7. The extent of effected caribou habitat is expected to be less than the total Project footprints because (i) substantial portions of the RSA are covered by recent burns where lichen is reduced or absent, (ii) the location of Project features have been planned to reduce overlap with high-value caribou habitat, and (iii) lichen cover is expected to partially persist on seismic lines ≤3 m wide.

All Project features will be developed during the winter, and vegetation clearing will be limited to trees and tall shrubs. The ground vegetation layer, including mosses, lichens, forbs, low shrubs, and tree seedlings will be left intact and protected from disturbance by compacted snow or rig mats, depending on the feature

type and site conditions. Maintaining ground vegetation will limit potential effects on caribou habitat by keeping caribou forage (i.e., lichen) and hasten vegetation regeneration by maintaining tree and shrub seedlings on the sites. The narrow widths of seismic lines (≤3 m) and the small sizes of well sites (≤2 ha) will also minimize habitat effects. The combination of the small size of the features and their dispersed pattern across the landscape is expected to minimize further potential habitat effects on a wide-ranging species, like caribou, which typically travel several kilometres per day.

Direct habitat effects are expected to be fully reversible, but the time for lichen to recover will vary depending on the width/size of the opening. For features >3 m wide, the time for lichen recovery is expected to be similar to, but somewhat shorter than, recovery after wildfire[20], due to the maintenance of the ground vegetation layer. Some studies have observed that vegetation recovery on conventional seismic lines has been delayed or stagnated (Lee and Boutin 2006, Jorgenson et al. 2010). However, both studies were of conventional lines where the ground vegetation was removed, and the soil was disturbed. Also, those study areas were subject to local factors that do not occur in Eagle Plains. For example, in the boreal forest of northern Alberta, where Lee and Boutin (2006) conducted their research, recovery of shrubs and trees was inhibited by (i) off-highway vehicle use and conversion of lines to roads and trails and (ii) a combination of site factors that favoured the persistence of graminoids and forbs and inhibited the initiation and growth of shrubs and trees. These factors are not an issue in Eagle Plains. Baseline studies of historical linear features in the RSA, including winter access roads, conventional seismic, and low-impact seismic, of various ages, found that most sites were undergoing normal successional pathways; only 5% of sites had stagnated at a forb stage (mostly on winter access roads) (**Appendix 9-B**). All low-impact seismic lines were undergoing normal succession, including growth of shrubs and tree seedlings/saplings left behind during vegetation clearing.

For features ≤3 m, where lichen cover is expected to persist on most lines, the time for lichen to return to pre-disturbance levels is expected to be much shorter. In the first several years after clearing, the extent of lichen cover could change due to the change in light and other environmental conditions and in response to the regeneration of other plants. However, those effects are expected to be site-specific and have a relatively small effect on the overall extent of lichen cover. At the small scale of ≤3 m wide openings, changes in microsite conditions can be positive or negative for lichen cover (Golder Associates 2016, Dabros et al. 2017, 2022). Over time, as vegetation regenerates on the line and continues to grow adjacent to the line, lichen cover is expected to return to pre-disturbance levels. The period over which this will occur is uncertain but is estimated to be two or three decades (compared to up to several decades for open areas following primary successional pathways).

[20] Lichen biomass generally peaks in stands 125-175 years old in the taiga (Klein 1982), though studies in Eagle Plains indicate that lichen can be relatively abundant in regenerating stands <50 years old (Russell et al. 1993).

Table 9-11. Characterization of Residual Direct Habitat Effects on Caribou

Criterion		Rating	Rationale
Magnitude		Negligible (Ecoregion) to Low (Region)	The extent of direct habitat effects on rut/late fall and winter habitat are 0.2% in Eagle Plains (Ecoregion) and up to 2% in the RSA (Region). Vegetation clearing along seismic lines, well pads and winter access roads will maintain existing ground vegetation, which maintains some caribou forage, maintains the existing vegetation community, and hastens regeneration. Overall, effects are expected to be negligible (<1% in Eagle Plains) to Low (1–10% in RSA) in magnitude based on the extent of direct habitat effects. However, the relative magnitude of effect on forested sites (where trees are cleared) will be higher than on non-forested and early seral sites (e.g., burns).
Likelihood		Certain	The probability of vegetation clearing causing direct habitat effects is certain.
Geographic Extent		Maximum Disturbance Footprint and Ecoregion	Exploration activities could occur at low density across much of the RSA, specifically the maximum disturbance footprint. Existing disturbances (including linear features) are present in the Eagle Plains ecoregion.
Duration, Frequency and Timing	Duration	Short-term to Long-term	Duration of effects depends on vegetation stage. On non-forested and early seral sites, effects are expected to be short-term. On forested sites, it may take up to several decades for trees to regenerate to the stage they were at when cut.
	Frequency	Continuous	Direct habitat effects are typically instigated as a single event (i.e., vegetation clearing), but the residual effect of that clearing will be continuous until the vegetation has regenerated.
	Timing	Year-round	Direct habitat effects are typically instigated as a single event (i.e., vegetation clearing), but the residual effect of that clearing will occur year-round. Note: a year-round effect does not imply that vegetation clearing occurs year-round; clearing will only occur during winter.
Reversibility		Reversible	Baseline studies and Yukon Government studies have examined regeneration patterns on historical linear features in Eagle Plains and found most sites are exhibiting normal succession, which are likely to result in similar vegetation communities and structures that occurred prior to disturbance.

9.6.2.1 Context and Confidence

Determining residual direct habitat effects on caribou considered the context of Regional Land Use Planning and the confidence in accurately quantifying and predicting those effects (**Table 9-12**). The effects characterization is consistent with the objectives of existing Land Use Plans, and there is relatively high confidence that effects were accurately captured in the assessment. A potential data limitation to this assessment is the temporal coverage (2012–2021) of GPS collar data used to quantify habitat quality for

the PCH; most of these caribou occupied the RSA in only one year. However, the RSF models used to quantify habitat quality identified consistent habitat selection patterns within rut/ late fall and winter seasons ranges that matched expectations of caribou habitat use. Therefore, the confidence in this assessment is high.

Table 9-12. Characterization of Context and Confidence in the Residual Project Effects on Caribou Direct Habitat Effects

Criterion	Rating	Rationale
Context	Conforms to Regional Land Use Plans	The RSA is within Land Management Unit IV zones of the North Yukon and Peel Regional Land Use Plans, which are areas zoned for the highest level of development. The Project activities are consistent with the integrated resource management objectives of the LUPs.
Confidence	High	There is high confidence in (i) the characterization of initial effects and (ii) the persistence and reversibility of direct habitat effects.

9.6.3 Residual Indirect Habitat Effects

Indirect habitat effects refer to reduced use of 'selected' (moderate and high quality) habitats by caribou due to sensory disturbances from adjacent areas (also referred to as reduced habitat effectiveness). Several Project activities, including winter access road construction and operation, seismic exploration, well development and operation, and camp operations, can potentially cause indirect habitat effects.

To characterize residual indirect habitat effects, results of PCH baseline studies were considered and ZOI estimates from other studies were evaluated in the context of the Project's activities, the Eagle Plains environment, the PCH's ecology, and potential mechanisms (pathways). Based on the range of ZOI distances reported in the literature and the factors that affect them, a ZOI distance of 1 km for linear features (seismic lines and winter access roads) and 3 km for facilities (well sites, camp, airstrip) is used to account for sensory disturbances associated with Project activities. These ZOI distances account for the weak effects of linear features estimated in PCH baseline studies (**Section 6 Caribou** of **Appendix 9-A**), aligns with the broader literature (primary and technical reports; **Appendix 9-C**), and account for a caribou's ability to perceive disturbances via sight, smell, and hearing while on the Eagle Plains landscape (i.e., rolling topography with taiga vegetation).

Overall, sensory perception was the key consideration in choosing ZOI distances rather than assuming caribou could develop a learned avoidance response to the Project. Based on the nature of the Project's exploration activities and the PCH's occurrence and movement patterns, caribou have limited opportunity to develop a learned response.

The following factors limit the potential for caribou to develop a learned response to the Project:

- The RSA constitutes a small portion of the rut/ late fall and winter ranges of the PCH, and most of the herd is unlikely to be exposed to Project activities due to the herd's broad distribution in Yukon and Alaska.
- For caribou that do interact with the Project, their exposure is expected to be limited both seasonally and annually because (i) caribou tend to wander continuously through the rut/ late

fall and winter (Russell and Gunn 2017) and individuals typically spend a small portion of these seasons in the RSA (**Section 6 Caribou** of **Appendix 9-A**), and (ii) caribou often vary the areas they use in rut/ late fall and winter from year to year (Russell et al. 1993).

- The Project's active work areas will vary from year to year, so the potential for caribou to encounter disturbances in the same area in multiple years, which could reinforce a learned response, is reduced.

The combination of these factors reduces the potential for the PCH to develop learned behaviours that would result in ZOI distances beyond sensory perception distances. ZOI distances of 1–3 km are on the lower end of the range of ZOI distances reported in the literature, but it is consistent with several studies of similar disturbances in forested areas (Dyer et al. 2001, Schindler et al. 2007, Polfus et al. 2011, MacNearney et al. 2021). From an assessment perspective, the precise choice of ZOI distances will have a limited effect on the estimates of indirect habitat loss because seismic lines are proposed to potentially occur across most of the RSA, and the distance between seismic lines is often less than 1 km. Thus, a 1-km ZOI will result in almost complete coverage within an annual work area. Consequently, the larger ZOI (3 km) associated with facilities will often overlap with the ZOIs of linear features.

This assessment assumes that habitat effectiveness is reduced by 75% within the 1-km (linear features) and 3-km (facilities) ZOIs. To calculate indirect habitat effects, 75% of 'selected' habitat within the ZOIs of Project features and activities was considered disturbed. This estimate is assumed to be biased to overestimate potential effects. The combination of ZOI distance and magnitude of effect results in a precautionary assessment, especially since the timing of indirect habitat effects will occur during the two seasons of least ecological importance to caribou and when caribou are most tolerant of human disturbance.

The presence of indirect habitat effects is tied directly to the occurrence of mechanized Project activities that cause sensory disturbances. The duration of Project activities will vary depending on the type of activity and site conditions. For this assessment, Project activities are assumed to persist for a full season. Many wells and winter access roads will only be active for part of the season. Similarly, seismic exploration operations will likely only cause sensory disturbance in approximately a third of the annual work area at any given time. Assuming that Project activities will occur for the entire season likely overestimates the potential effects. It provides a conservative assessment (i.e., errs on the side of a greater rather than a lesser potential effect). Indirect habitat effects will not result in the permanent loss of any caribou habitat. The effects will result in animals temporarily avoiding habitat areas for the year when exploration activities are active. Those areas will be available to caribou again in years after exploration is complete.

Due to the dynamic nature of the exploration program (i.e., the location and scheduling of work areas will be continually evolving as results are obtained), the location of work areas cannot be planned at this stage. Therefore, instead of calculating indirect habitat effects for specific work areas for each year of the Project, the total indirect habitat effects were estimated for the full life of the Project. Ten well site development scenarios and access routes were evaluated. The indirect habitat effects over the Project's lifetime are summarized in **Table 9-13**.

In the RSA, the maximum indirect habitat effect expected to occur in any given year is approximately 32% of the Project's total lifetime effect. This annual effect was estimated by multiplying the total indirect habitat effects (maximum 692.9 km² during rut/ late fall and 457.6 km² during winter), due to existing conditions

and the Project, by the proportion of the RSA in which operations will be conducted annually. To be prudent in this assessment (i.e., err on the side of overestimating an effect), the proportion of annual operations (i.e., area of annual operations/area of RSA = 500 km² / 2,387 km² = 0.2) was increased by an additional 50% to account for Project features like winter access roads and the camp, which occur outside of the exploration area (i.e., final proportion = 0.2 x 1.5 = 0.3). Therefore, annual sensory disturbance in the RSA is estimated to reduce habitat effectiveness by 221.7 km² (23.0%) during rut/ late fall and 146.4 km² (23.2%) during winter. Additionally, at the scale of the Eagle Plains ecoregion, an annual sensory disturbance is estimated to reduce habitat effectiveness by 487.1 km² (5.8%) during rut/ late fall and 280.6 km² (5.1%) during winter. Annual, indirect habitat effects at the ecoregion scale are calculated by subtracting the lifetime effects of the RSA from those of the ecoregion (e.g., fall: 958.3 km² – 692.9 km² = 265.4 km²) and adding the difference to the annual RSA effect (e.g., fall: 221.7 km² + 265.4 km² = 487.1 km²). Again, these estimates are biased to overestimate potential effects and, thus, provide a more prudent (i.e., likely overestimate the effect) assessment.

Table 9-13. Indirect Habitat Effects from Existing and Project-related Disturbances on 'Selected' Caribou Habitat During Rut/ Late Fall and Winter in the Project Regional Study Area (2,387 km²) and the Eagle Plains Ecoregion (21,984 km²)[1,2]

Effects Category	Rut and Late Fall		Winter	
	RSA	Ecoregion	RSA	Ecoregion
Existing (Baseline), Indirect Effects	53.0 km² (5.5%)	273.7 km² (3.3%)	9.1 km² (1.4%)	111.7 km² (2.1%)
Project Wellsite Scenarios (n = 10), Indirect Effects	625.0–639.9 km² (64.8–66.3%)	661.4–684.7 km² (7.9–8.2%)	443.8–448.5 km² (70.2–70.92%)	473.8–480.0 km² (8.7–8.8%)
Total Indirect Effects on 'Selected' Habitat	678.0–692.9 km² (70.3–71.80%)	935.1–958.3 km² (11.1–11.4%)	452.9–457.6 km² (71.6–72.4%)	585.6–591.7 km² (10.7–10.9%)
'Selected' Habitat Unaffected by Sensory Disturbance	272.2–287.1 km² (28.2–29.7%)	7,441.6–7,464.9 km² (88.6–88.9%)	174.8–179.5 km² (27.6–28.4%)	4,863.5–4,869.6 km² (89.2–89.3%)
Total 'Selected' Habitat	965.1 km² (100.0%)	8,400.0 km² (100.0%)	632.4 km² (100.0%)	5,455.2 km² (100.0%)

1 The Project's effects are calculated based on the lifetime of the exploration program.

2 Indirect habitat effects refer to reduced habitat effectiveness due to sensory disturbances. These effects are calculated independently from the direct habitat effects caused by vegetation clearing (see Table 9-10 in Section 9.6.2 Residual Direct Habitat Effects). Direct habitat effects would be subtracted from 'Selected' Habitat Unaffected by Sensory Disturbance and added to Total Indirect Effects on 'Selected' Habitat to calculate the total amount of (direct and indirect) disturbance.

* Percentages are relative to the total amount of 'selected' caribou habitat during rut/ late fall and winter seasons.

A summary of the characterization of residual indirect habitat effects on caribou is provided in **Table 9-14**. Applying 1-km (linear features) and 3-km (facilities) ZOIs around Project features results in the potential for indirect habitat effects of approximately 70–72% of the RSA over the Project's lifetime, reflecting the extensive distribution of seismic operations. In the broader Eagle Plains ecoregion, indirect habitat effects occur in approximately 11% of the total area over the Project's lifetime. In any given year, indirect habitat effects could result in about 23% reduced habitat effectiveness in the RSA and approximately 5–6%

reduced habitat effectiveness in the Eagle Plains ecoregion. Indirect habitat effects are temporary and cease once Project activities end. Indirect habitat effects will not result in the permanent loss of any caribou habitat. The effects will likely result in most caribou temporarily avoiding 'selected' habitat areas within an annual work area for the year when exploration activities occur. Those areas will be available to caribou again in the years after exploration is completed.

The magnitude of indirect habitat effects on the PCH is low at the population level (Ecoregion and Seasonal Ranges). The annual work areas are small relative to the rut/ late fall and winter season ranges, so a relatively small proportion of the population is likely to be affected. The residency time of caribou occurring in annual work areas is expected to be short (e.g., 1–2 weeks during winter), and caribou will have alternative habitat available to them outside annual work areas. The energetic cost for affected animals to use alternative habitat is expected to be relatively low because PCH caribou are typically in good body condition in fall and winter and usually travel several kilometres per day during these seasons, regardless of their proximity to disturbances. Therefore, the magnitude of indirect habitat effects is moderate at the RSA level.

The duration of indirect habitat effects is assumed to be directly tied to the operational period of Project activities that cause sensory disturbances. Once the disturbances stop, effects on caribou are expected to end. From a practical perspective, and to be conservative in estimating potential effects, it is assumed that effects could be associated with all Project features within an annual work area, during the entire season that area is active. Large portions of the annual work areas will likely not be subject to disturbances at any given time. However, due to the dispersed and variable nature of the work (e.g., having several seismic crews active at one time), it is impossible to predict the location and timing of disturbance in an annual work area. In years when human activity is not present (i.e., after exploration activities are complete), it is assumed that indirect effects on habitat do not persist.

Table 9-14. Characterization of Residual Indirect Habitat Effects on Caribou

Criterion	Rating	Rationale
Magnitude	Low (Ecoregion) and Moderate (Region)	The extent of indirect habitat effects in any year (i.e., an annual work area) is approximately 5% of the Eagle Plains (Ecoregion) and approximately 23% of the RSA (Region). Furthermore, within an annual work area, only approximately one-third (32%) of that area will likely be subject to disturbance at any given time within a season. The magnitude of effect at the Ecoregion level (Eagle Plains) is Low (1–10%) because most of the population is not expected to overlap with the annual work area in a given year, and those caribou have alternative habitat available. The magnitude of effect at the Region (RSA) level is Moderate (11–35%) because, although the annual work area constitutes a substantial portion of the RSA, (i) some caribou are still expected to use habitat within the ZOI, and (ii) caribou are a wide-ranging species, and there is relatively low impact to individual animals to use alternative habitat outside the affected annual work area.
Likelihood	Certain	The probability of Project activities causing indirect habitat effects is certain.

Criterion		Rating	Rationale
Geographic Extent		Region and Ecoregion	Indirect habitat effects could affect regional (RSA) and ecoregion (Eagle Plains) in any given year. Indirect habitat effects within the RSA could affect caribou distribution and habitat use beyond the RSA.
Duration, Frequency and Timing	Duration	Short-term	Most Project activities will last several weeks or months within a year. For this assessment, effects are assumed to occur for an entire season, to be precautionary.
	Frequency	Continuous	Indirect habitat effects are tied directly to mechanized Project activities. Most Project activities (seismic exploration, well development, winter access roads, and camp operations) will occur continuously within an annual work area during the period in which they occur. However, not all activities are expected to occur in the same year.
	Timing	Seasonal	Indirect habitat effects are tied directly to mechanized Project activities. Project activities (seismic exploration, well development, winter access roads, and camp operations) will occur seasonally, with the majority of these activities occurring in the winter.
Reversibility		Reversible	Indirect habitat effects are completely reversible. Once the sensory disturbance associated with mechanized activity stops, indirect habitat effects are expected to end.

9.6.3.1 Context and Confidence

The characterization of residual indirect habitat effects on caribou considered the context of Regional Land Use Planning and the confidence in accurately quantifying and predicting those effects (**Table 9-15**). The effects characterization is consistent with the objectives of existing Land Use Plans. There is moderate confidence that effects were accurately captured in the assessment; uncertainty remains regarding the ZOI distance and degree of caribou use within the ZOI. For example, a potential data limitation to this assessment is the temporal coverage (2012–2021) of GPS collar data used to quantify ZOIs; most of these caribou occupied the RSA in only one year. However, to be prudent, the potential effects (i.e., degree of avoidance within a ZOI) were overestimated to account for any uncertainties.

Table 9-15. Characterization of Context and Confidence in the Residual Project Effects on Caribou Indirect Habitat Effects

Criterion	Rating	Rationale
Context	Conforms to Regional Land Use Plans	The RSA is within Land Management Unit IV zones of the North Yukon and Peel Regional Land Use Plans, which are areas zoned for the highest level of development. The Project activities are consistent with the integrated resource management objectives of the LUPs.
Confidence	Moderate	There is moderate confidence associated with the ZOI distance and the degree to which some caribou will still use habitats within the ZOI. However, assumptions about the extent and timing of work are biased to overestimate potential effects to provide a more prudent assessment.

9.6.4 Residual Movement Effects

The Project can potentially affect caribou movements by creating sensory disturbances that result in avoidance of those areas by caribou. A summary of the characterization of residual movement effects on caribou is provided in **Table 9-16**.

The magnitude of residual effects on caribou movements depends on the scale of analysis. Most caribou travelling through the rut/ late fall and winter ranges will not be exposed to the Project. Based on the relatively small size of annual work areas compared to PCH rut/ late fall and winter seasonal ranges (≤1% of the seasonal ranges by area), a relatively small proportion of the PCH population is likely to be exposed to Project activities that could affect movement. Any residual effects at broader scales (Ecoregion and Seasonal Range) are predicted to be relatively small, and caribou are predicted to successfully proceed with broad seasonal movements/migrations across their seasonal ranges. Effects on seasonal migration movements are unlikely.

For caribou that do travel through or around the annual work area, the most likely effects are elevated energetic output or stress. Any effects on movement that do occur are expected to be limited to local alterations to the location and timing/rate of movement within the RSA. Modified movement responses could include (i) delayed movement upon encountering the Project, (ii) deflected travel routes around the Project, or (iii) modified movement patterns locally, within the RSA, possibly including slower or faster travel rates, or more tortuous travel paths. These local movement modifications, if they occur, could cause indirect effects on individual animals, such as stress or increased energy expenditures, but are unlikely to impede broad movements among seasonal ranges. The potential magnitude of these secondary effects (i.e., stress and energetic costs) are limited because caribou are typically in good body condition during rut/ late fall and winter, and caribou can modify their movements to avoid the annual work areas. Therefore, the magnitude of effects on movements at the RSA level is rated moderate.

Based on typical daily movement rates, the exposure period would be limited to a few days, and the distances associated with avoiding active work sites are small relative to normal rut/ late fall and winter movement patterns. The potential for negative effects is also reduced because caribou are typically in good body condition in rut/ late fall and winter and are not subject to stressors they experience in other seasons, such as insect harassment and heat stress. Like indirect habitat effects, the duration of Project effects on caribou movement is expected to be limited to periods when the Project is active and causing sensory disturbances (refer to the information provided in **Section 9.6.3 Residual Indirect Habitat Effects**).

Effects on movement are expected to be temporary and will be limited to the year that the Project is active within a given annual work area. Once sensory disturbances stop, movement effects are expected to end so that caribou resume normal movement patterns. The persistence of habitat disturbances associated with the exploration activities (seismic lines, winter access roads, and well sites) are not expected to affect caribou movements when no mechanized activity is associated with those features, i.e., in the absence of sensory disturbances. Historical telemetry data (2012–2021) shows that in years that PCH caribou occurred in the RSA (2015), caribou regularly travelled along and across historical seismic lines and winter access roads, though it appears that some caribou avoid crossing certain sections of the Dempster Highway (**Section 6 Caribou** of **Appendix 9-A**).

Table 9-16. Characterization of Residual Movement Effects on Caribou

Criterion		Rating	Rationale
Magnitude		Low (Ecoregion and Seasonal Range) to Moderate (Region)	For caribou interacting with the Project, animals are predicted to successfully complete seasonal movements/migrations across their seasonal ranges. Still, they may exhibit modified movement patterns that elevate stress and energy expenditures. The magnitude of effect related to movement is associated with the level of sensory disturbance that could affect caribou movement: approximately 23% of the RSA and about 5% of the Eagle Plains ecoregion, annually. The magnitude is rated Low (1–10%) at the Ecoregion (Eagle Plains) and Seasonal Range (rut/ late fall and winter) scales. The maximum annual work area size is approximately 2% of the late fall and winter seasonal ranges. Most of the PCH will not interact with the annual work area. The magnitude is rated Moderate (11–35%) at the RSA (Region) level. The maximum size of annual work areas is expected to be approximately 30 km in diameter or a third of the RSA.
Likelihood		Certain	The probability of Project activities affecting local caribou movements within the RSA is high. However, affected caribou are still expected to complete seasonal movements/migrations.
Geographic Extent		Region, Ecoregion, and Seasonal Range	Project activities affecting caribou movements could occur over as much as a third of the RSA in any given year. Effects on movement could extend outside the RSA to broader seasonal ranges.
Duration, Frequency and Timing	Duration	Short-term	Based on average daily movement rates of caribou of 4.4 km/day in winter and maximum annual work areas of 30 km in diameter, caribou within or adjacent to the RSA would be exposed to sensory disturbances that could affect their movement for approximately 1–2 weeks.
	Frequency	Irregular	Caribou wander throughout rut/ late fall and winter seasons, and their movement patterns are expected to result in multiple, irregularly timed interactions with the Project.
	Timing	Seasonal	Project activities will occur seasonally, with the majority of these activities occurring in the winter.
Reversibility		Reversible	Effects on caribou movements are reversible. Once Project activities stop, any effects on caribou movement are expected to cease. Telemetry data shows that the PCH regularly cross historical features similar to what the Project will create.

9.6.4.1 Context and Confidence

The characterization of residual movement effects on caribou considered the context of Regional Land Use Planning and the confidence in accurately quantifying and predict those effects (**Table 9-17**). The effects characterization is consistent with the objectives of existing Land Use Plans. There is moderate confidence

in how Project features and activities may affect local caribou movements within the RSA. Expected caribou movement through the RSA is mostly informed by GPS collar data of PCH caribou in a single year (2015) out of nine (2012–2015). Yet, those data also suggest that caribou occurrence in the RSA is relatively infrequent. There is higher (but still moderate) confidence that movement effects at broader scales (Ecoregion and Seasonal Range) will affect only a small proportion of the PCH subpopulation. However, there is still uncertainty about how many caribou could be affected. Overall, a synthesis of the literature and PCH data suggests that movement effects at broad scales will be limited given (a) the widespread distribution of the subpopulation, (b) the minimal traffic along linear features in the RSA, and (c) the dispersed and low density of active exploration (i.e., wells, traffic) in the RSA.

Table 9-17. Characterization of Context and Confidence in the Residual Project Effects on Caribou Movement Effects

Criterion	Rating	Rationale
Context	Conforms to Regional Land Use Plans	The RSA is within Land Management Unit IV zones of the North Yukon and Peel Regional Land Use Plans, which are areas zoned for the highest level of development. The Project activities are consistent with the integrated resource management objectives of the LUPs.
Confidence	Moderate	There is moderate confidence that movement effects will be limited to a small proportion of the PCH and that caribou that encounter the annual work area will likely not be prevented from completing seasonal movements. There is moderate certainty about how caribou in the annual work area may modify their local movements and the consequences of those modifications.

9.6.5 Residual Direct Mortality Effects

The potential pathways for the Project to cause direct mortality to caribou are limited to vehicle collisions. Measures associated with winter access road use and maintenance (**Section 9.5.6 Access Road Use and Maintenance**) are expected to mitigate this risk entirely. Therefore, residual direct mortality effects are considered negligible and are not characterized.

9.6.6 Residual Indirect Mortality Effects

The Project can potentially cause indirect mortality to caribou by creating linear features (winter access roads and seismic lines) that can enhance access and hunting efficiency of humans and wolves (facilitated predation). Indirect mortality associated with linear feature development has been linked to substantial population declines in specific herds of boreal and mountain caribou in Alberta and BC.

The Project is expected to create an extensive network of winter access roads and seismic lines that will theoretically result in indirect mortality to caribou (via facilitated predation and apparent competition). However, several factors associated with the Project, such as environmental conditions, ecology of the PCH, and land use practices in the Eagle Plains area, reduce the potential for indirect mortality.

Project Factors

- The primary type of linear features created by the Project are 3D LIS lines. Studies that have observed indirect mortality associated with linear features are where wider linear features (historical 2D seismic, pipelines, transmission lines, and roads) predominate (James and Stuart-Smith 2000, Latham et al. 2011a, DeMars and Boutin 2018). The low-impact seismic (LIS) planned for the Project has inherent characteristics, plus specific mitigation measures, that limit the potential for both apparent competition and facilitated predation:
    - In terms of apparent competition, the narrow width of the LIS lines limits the development of dense shrub production (i.e., as browse for moose) (Golder Associates 2016; **Appendix 9-B**).
    - In terms of facilitated predation, ease of travel and sightlines along the lines for predators and humans are limited by the narrow line widths, curves/bends in the lines, limited connectivity to roads, and vegetation piling (**Appendix 9-B**). Studies of 3D LIS lines in other areas indicate that use by wolves is dramatically reduced compared to other lines, likely due to the line width and vegetation height, and often does not differ from undisturbed habitats (Dickie et al. 2017, Keim et al. 2021).
    - The Project is minimizing the development of new winter roads by reactivating a relatively extensive network of historical winter roads in the area.
    - While the Project is active, access by hunters along Project roads and trails will be limited due to safety issues for Project staff and hunters. Safety controls will limit the potential for facilitated hunting to occur.

Environmental Factors

- The potential for indirect mortality associated with apparent competition (i.e., elevated wolf densities) in Eagle Plains is limited, relative to studies in southern areas, by two factors:
    - Alternative prey in the region is limited to moose. Deer, which have been attributed as important alternative prey in some studies (Darby and Duquette 1986, Latham et al. 2011b, Serrouya et al. 2016), are absent.
    - The region's northern latitude is assumed to result in relatively low forage productivity and moose densities. Population surveys for moose have not been conducted in Eagle Plains, but moose densities are estimated to be low compared to parts of southern Yukon (M. Suitor, n.d., pers. comm.).
- One study reported that wolf densities in a northern region of the boreal in Northwest Territories (NWT), with moose and caribou, were only a tenth of the density compared to an area in the southern boreal in Alberta, with caribou, moose and deer (Serrouya et al. 2016).
- The migratory nature of the herd limits the degree to which wolves can numerically respond to elevated caribou numbers (i.e., the density of non-migratory wolves is limited by their local, year-round prey base, Hayes and Russell 2000). A study of wolf predation on the PCH estimated that wolves killed about 7,600 adult caribou yearly, regardless of herd size (Hayes and Russell 2000).
- Although wolves are the primary predators of barren-ground caribou, wolf predation does not appear to regulate barren-ground caribou herds (Crête and Huot 1993, Messier 1995, Hayes and Russell 2000). However, the limiting effect of predation increases as population size

decreases, which can result in a cumulative effect with other limiting factors as the population declines (COSEWIC 2016). Hayes and Russell (2000) estimated that the predation rate would have had to be near twice the observed level to cause the PCH to decline during their study.

Factors Related to PCH Ecology

- The large seasonal ranges and the movement patterns of the PCH limit the degree to which caribou are exposed to potential effects of indirect mortality at both the population and individual animal levels. In subpopulations of woodland caribou where habitat-mediated predation is an issue, habitat effects often occur over large parts of the annual ranges of those herds.
    - The annual work area of the Project constitutes 2% of the PCH's rut/ late fall and winter ranges. Therefore, the potential effects of habitat-mediated predation are expected to be limited to a small proportion of the population.
    - The PCH tend to travel continuously through the fall and winter. Based on existing evidence (i.e., PCTC-derived seasonal ranges, 1970–2016; GPS telemetry data, 2012–2021), caribou that use the RSA are likely to be present for a small portion of the fall or winter, limiting their exposure period to indirect mortality risk from the Project. Historical residency times of collared caribou within the RSA averaged 16 days, corresponding to 13% of the winter season. The estimated period of exposure for caribou within an annual work area (a third of the RSA) is 5.5 days or 4% of the winter season.
- The PCH is presently at high population level and predation effects tend to be lower per capita at high densities (COSEWIC 2016).
- The migratory nature of the herd limits the degree to which wolves can numerically respond to elevated caribou numbers. (i.e., The density of non-migratory wolves are limited by their local, year-round prey base).
- Fall and winter are seasons when the PCH are typically least vulnerable to predation.
    - On average, animals are in good body condition. Young of the year have matured to a point where they are less vulnerable to predators.
    - The herd is at its most dispersed distribution.

Factors Related to Land Use

- In winter, the degree to which wolves use linear features depends on whether the snow on the lines is packed by human use. Human use of the Eagle Plains area in the winter is low in most years and few lines are packed (Dickie et al. 2017, Keim et al. 2021).
- Humans using linear features can extend the number of years predators use linear features by inhibiting vegetation regeneration (Lee and Boutin 2006). However, baseline studies of historical linear features in the RSA did not observe any evidence of human use after the oil and gas exploration work that created the features that inhibited regeneration (**Appendix 9-B**).

A summary of the characterization of residual indirect mortality effects on caribou is provided in **Table 9-18.** Due to the complexity of the factors involved, it is difficult to quantify the degree to which the Project may result in elevated indirect mortality of caribou. If indirect mortality were to result from the Project, the magnitude and duration of effects would likely be limited to the annual work areas in the years they were active, specifically when Project activities result in snow packing along linear features. The effects of indirect

mortality are expected to be negligible in years following exploration work, so long as there continues to be limited human activities in Eagle Plains that could pack the snow on linear features. If caribou avoid the annual work areas due to sensory disturbances (i.e., indirect habitat loss), the effects of the Project on indirect mortality could be negligible.

This assessment assumes a maximum 25% increase in predation due to the Project, which is precautionary (i.e., the 25% level is biased to overestimate effects). Twenty-five percent (25%) is likely the maximum capacity by which wolves can increase their functional response[21]. Accounting for the mitigating factors, outlined in **Section 9.5.3 Access Management**, that could limit indirect mortality, the magnitude of indirect effects will probably be much lower than 25%. If caribou avoid the annual work areas due to sensory disturbances (i.e., indirect habitat loss), the effects of the Project on indirect mortality could be negligible.

The increased potential for indirect mortality within the RSA would translate to a minimal population-level effect. The size of the annual work areas is simply so small, relative to the size of the rut/ late fall and winter seasonal ranges (approximately 2% of these ranges), that the majority of the PCH would not be exposed to Project effects for most of the rut/ late fall and winter seasons. To demonstrate the low magnitude of this effect, an overly cautious scenario is presented:

Assuming a reduced PCH subpopulation size of 152,000 caribou and 7,600 kills/year by wolves (Hayes and Russell 2000), the background predation rate during rut/ late fall and winter seasons would be approximately 5.0%. If caribou were distributed roughly evenly across the seasonal ranges, approximately 0.1% of that background mortality would occur within the Project's annual work area. Thus, if the Project facilitated predation by increasing the predation rate in an annual work area by 25% (which is very unlikely due to limitations in the functional response of wolves), then the herd's overall predation rate would not rise beyond 5.0%—a <0.1% increase. At the Seasonal Range scale, this equates to a 0.5% increase; at the Ecoregion scale (Eagle Plains), this equates to a 2.2% increase.

Table 9-18. Characterization of Residual Indirect Mortality Effects on Caribou

Criterion	Rating	Rationale
Magnitude	Negligible (Seasonal Range), Low (Ecoregion), and Moderate (Region)	For indirect mortality, magnitude refers to the extent to which the effect could occur. The magnitude of the effect is rated negligible (<1%) at the Seasonal Range (rut/ late fall and winter) scales because the annual work area size is only 2% of the rut/ late fall and winter seasonal ranges. Thus, only a small proportion of the population would be exposed to the effects. A maximum potential effect at this scale would be a <0.1% increase in predation. Furthermore, several factors associated with the Project activities, regional land use patterns, environmental conditions, and the ecology of the PCH reduce the potential for facilitated predation to occur in Eagle Plains. The magnitude of the effect is rated Low (1–10%) at the Ecoregion (Eagle Plains) scale because the overall rate of predation would be higher than in Seasonal Ranges

[21] A functional response is the change in the rate of predation that a fixed number of predators vary by, in relation to changes in factors that affect hunting efficiency and prey handling times.

Criterion		Rating	Rationale
			(due to a smaller area) but lower than the RSA. The maximum expected increase at this scale is a 2.2% increase in predation. The magnitude of the effect is rated moderate (11–35%) on the Region (RSA) scale because up to a third (32%) of the RSA could be subject to indirect mortality effects each year the Project is active. The maximum expected increase in predation is 25%, which is biased to overestimate effects.
Likelihood		Probable	The likelihood of Project activities resulting in indirect mortality is rated probable because, although the Project will create packed linear features that could result in facilitated predation, factors associated with the Project activities, regional land use patterns, environmental conditions, and the ecology of the PCH reduce the potential for facilitated predation to occur in Eagle Plains.
Geographic Extent		Region, Ecoregion, and Seasonal Range	The effects of indirect mortality will be associated with linear features within the RSA, but local mortality events within the RSA could translate to population effects at the broader Ecoregion and Seasonal Range scales.
Duration, Frequency and Timing	Duration	Short-term	The conditions that support indirect mortality by wolves, packing of snow along liner features, are assumed to occur for the entire exploration season within the annual work area. Effects are not expected to occur in subsequent years when Project activities do not pack snow.
	Frequency	Irregular	Within a given year, conditions that could lead to indirect mortality will persist along snow-packed linear features within an annual work area. However, the frequency is irregular and dependent on caribou occurrence on linear features.
	Timing	Seasonal	Within a given year, conditions that could lead to indirect mortality are mostly limited to winter within an annual work area. Sightlines and ease of travel are unlikely to be improved for predators/hunters during other seasons, but not impossible.
Reversibility		Reversible	Effects of indirect mortality are entirely reversible. Effects are expected to be limited to annual work areas in the year when exploration activities are active. Effects are not expected in years following the work because features with unpacked snow are not expected to support facilitated predation.

9.6.6.1 Context and Confidence

The characterization of residual indirect mortality effects on caribou considered the context of Regional Land Use Planning and the confidence in accurately quantifying and predicting those effects (**Table 9-19**). The effects characterization is consistent with the objectives of existing Land Use Plans. There is moderate confidence in how Project features and activities may facilitate predation within the RSA. Without data on wolf densities and predation rates, effects were overestimated to be prudent. It was assumed that the

maximum potential increase in predation rates would be 25% within the RSA. This overestimation at the RSA scale leads to a higher confidence that, on average, annual predation rates would not exceed <0.1% (Seasonal Range) or 2.2% (Ecoregion) increases relative to background predation rates.

Table 9-19. Characterization of Context and Confidence in the Residual Project Effects on Caribou Indirect Mortality Effects

Criterion	Rating	Rationale
Context	Conforms to Regional Land Use Plans	The RSA is within Land Management Unit IV zones of the North Yukon and Peel Regional Land Use Plans, which are areas zoned for the highest level of development. The Project activities are consistent with the integrated resource management objectives of the LUPs.
Confidence	Moderate (Region) to High (Ecoregion and Seasonal Range)	There is high certainty that the effects of indirect mortality would be limited to a small proportion of PCH across rut/ late fall and winter seasonal ranges. There is also high certainty that many of the fundamental factors contributing to the indirect mortality of caribou in other areas are reduced or not present in Eagle Plains. However, there is moderate uncertainty about the magnitude and severity of mortality in the RSA. Current harvest and predation rates in the RSA are unknown.

9.6.7 Residual Energetics Effects

The potential pathway for the Project to cause indirect energetic effects on caribou is through elevated energetic expenditures via altered behaviours or travel routes. However, the potential for the Project to have this effect on caribou is limited: (i) most caribou travelling through the rut/ late fall and winter ranges will not be exposed to the Project, and those that do will likely have a limited period of exposure (several days); (ii) the Porcupine caribou are typically in good body condition in rut/ late fall and winter; and (iii) the distances associated with avoiding active work sites are modest relative to regular rut/ late fall and winter movements. Like other indirect effects, the duration of effects on caribou energy expenditures are expected to be limited to periods when the Project is active and causing sensory disturbances. Once the disturbances stop, effects on energetics are expected to end.

Based on the limited potential for the Project to affect caribou energetics, and because such effects are mostly accounted for in the characterization of movement effects (**Section 9.6.4 Residual Movement Effects**), residual energetics effects are considered negligible and are not characterized further.

9.7 SIGNIFICANCE

The Project is not expected to substantially affect caribou habitat, movement, mortality, or energetics. Direct habitat effects reduce ‘selected’ caribou habitat by 2% within the RSA and 0.2% in the Eagle Plains ecoregion. Indirect habitat effects further reduce habitat effectiveness annually by 23% within the RSA and 5% in the Eagle Plains ecoregion. Therefore, the total habitat effects on ‘selected’ caribou habitat are approximately 25% within the RSA and about 6% in the Eagle Plains ecoregion. Overall, a large portion of total habitat effects are attributable to the extent of historical burns (<40-years old) on the landscape (i.e., approximately 47% of the RSA). Movement and indirect mortality effects are transient and depend on the degree of caribou interaction with annual work areas, which is moderate within the RSA (32%) and minimal

in the broader seasonal ranges (≤1%). Direct mortality and indirect energetic effects due to the Project are likely **negligible**.

Overall, there is moderate to high confidence in characterizing potential residual effects. Where there was uncertainty in the characterization, potential effects were overestimated to be precautious. However, all potential effects are reversible and are not likely to persist once Project activities are completed. Therefore, the collective residual effects on caribou from all potential sources (habitat, movement, mortality, and energetics) are **not significant**. These residual effects are unlikely to alter the population viability or persistence of PCH caribou at the scale of the Region (RSA), Ecoregion (Eagle Plains), or Seasonal Range (rut/ late fall and winter).

9.8 FOLLOW-UP MONITORING

Caribou mitigation and monitoring actions are consistent with adaptive management and will evolve through continued engagement and discussion. The proposed mitigations are based on the best available information (including the substantial analytical progress in this assessment to characterize the PCH's historical fall and winter habitat use and movements to support the current mitigation actions). However, the current knowledge (in terms of baseline information and predicted effects on caribou) has some limitations and uncertainty. Chance proposes monitoring and supplemental data collection programs/analyses to address those uncertainties. These programs will provide ongoing information to assess the success of the exploration program at mitigating effects on caribou, and to refine mitigation measures if required, as the level of knowledge about caribou use of the area increases over time.

Monitoring will have three components.

1. Compliance monitoring.
2. Wildlife training, observation, reporting, and response.
3. Applied Research and Effectiveness Monitoring.

9.8.1.1 Compliance Monitoring

An internal compliance audit will be conducted each month to verify and document that the various components of the Caribou Mitigation and Management Plan are being implemented. The results of this audit will be summarized in a monthly report. Key items in the report will include the following.

- A summary of the type and location of work conducted, including winter access road use and maintenance activities.
- A summary of all caribou observations, including locations, numbers, and behaviours.
- A detailed summary of any caribou encounters that triggered a site-specific response plan, including a summary of the implemented mitigation measures and the outcomes to caribou.

A Professional Biologist will review copies of the compliance monitoring reports each month. They will be made available to the Yukon Government, indigenous stakeholders, and the Porcupine Caribou Management Board upon request.

9.8.1.2 Caribou Observations and Reporting

Documenting observations of caribou by Project personnel will be a key tool for (i) monitoring the occurrence and distribution of caribou in the area and (ii) identifying local-scale interactions of caribou with the Project. As part of the broader wildlife observation reporting program, all caribou and caribou sign observations will be documented by Project personnel while in the field and submitted at the end of their shift to a central location in camp. Any observations of caribou will be reported directly to the Environmental Monitor via radio communication. The Environmental Monitor will review and enter the observations into a database weekly.

- All observations of caribou and caribou sign will be documented by Project personnel while in the field and recorded on tailored Wildlife Observation forms. Copies of Wildlife Observation forms will be kept in all Project vehicles, equipment, and camps.
- Key information to record for any wildlife observation includes the species, number of animals, activity/behaviour, date, time, observer name, location (e.g., access road name and km or well site number), GPS coordinates, and additional comments will be recorded.
    - For all occurrences along access roads, record whether the animal(s) crossed the access road or turned back from the access road, and, if the animals are on the access road, if they ran down the access road away from the vehicle and if so, for how far before moving off the access road.
- Any observations of caribou are to be passed on to other workers in the vicinity via two-way radio and reported to the Environmental Monitor as soon as possible. Digital copies of the observation forms will be submitted to the Environmental Monitor at the end of each shift.
- The Environmental Monitor will enter the caribou observations into the wildlife observation database daily, review the observations to determine whether any follow-up actions are required, and notify the Project Biologist, per the Caribou Interaction Response Plan.
- The Project Biologist will review the wildlife observation database weekly with any other available monitoring data.

9.8.1.3 Applied Research and Effectiveness Monitoring

Although the mitigation measures developed for caribou are supported by substantial information, it is recognized that some limitations of available information result in uncertainty about how caribou may respond to certain Project activities and features. In addition to the reactive monitoring activities outlined above, applied research studies may be initiated to address specific knowledge gaps or concerns identified by regulators and stakeholders. Specific studies have not yet been identified, pending feedback and discussion with regulators and stakeholders. Chance envisions leading or supporting relevant applied research studies if the Project is approved.

Examples of potential studies during the exploration program include:

- A remote camera study to quantify the use of linear features by caribou, wolves, and humans to (i) better understand the potential effects of indirect mortality on caribou, and (ii) determine the effectiveness of mitigation measures to reduce use by wolves and humans. Another study component could be establishing cameras at active well sites to document caribou occurrences and responses.

- A vegetation recovery study following completion of work in annual work areas to determine shrub and tree regeneration rates that affect the use of the lines for travel.

9.9 CUMULATIVE EFFECTS ASSESSMENT

9.9.1 Approach

Two potential cumulative effects were identified for caribou: (1) cumulative direct habitat and movement effects and (2) cumulative indirect mortality effects. Cumulative direct habitat and movement effects were combined because both are attributable to the amount of disturbance from anthropogenic activities. Characterizing cumulative effects on caribou generally follows the methods described in **Section 9.6.1 Approach** (see **Table 9-9**). These effects have each been characterized by magnitude, likelihood, geographic extent, duration, timing, frequency, reversibility, context, and confidence. However, the ratings assigned to each term differ by the cumulative effect type and are further described in the following sections.

The cumulative effects of the Project and other existing projects and activities were assessed at three spatial scales relevant to caribou: (1) Caribou Cumulative Effects Study Area (CCESA), (2) PCH rut/ late fall range, and (3) PCH winter range. Furthermore, the net cumulative effects of four scenarios were assessed: (1) present conditions, (2) the Project, (3) future projects and disturbances, and (4) the total cumulative effect into the future.

9.9.2 Cumulative Direct Habitat and Movement Effects

Three indicators were calculated to characterize cumulative direct habitat and movement effects on caribou: (1) total surface disturbance (area [km²] and percent [%]) from anthropogenic footprints (e.g., mineral exploration, oil and gas, transportation, communities, recreation; see **Table 3-7**); (2) total 'ECCC-defined disturbance' (km² and %), relevant to a herd's annual and seasonal ranges, and refers to the area disturbed by fires <40-years old and anthropogenic footprints plus 500 m buffers around those footprints; and (3) total disturbance (km² and %) to 'selected' caribou habitat within rut/ late fall and winter ranges. For indicator #3, disturbance due to 3D LIS lines were downgraded by 50% since lichen persists after these lines are cut (as completed in **Section 9.6.2 Residual Direct Habitat Effects**).

A summary of the cumulative effect indicators is provided in **Table 9-20**. At each spatial scale, the total surface disturbance is expected to be <1% and the net effect of the Project is expected to be a maximum of 0.10%. The total amount of ECCC-defined disturbance will likely be <19% at the PCH's annual range and ≤27% within seasonal ranges. However, most of these disturbances will occur either solely due to burns (<40-years old) or burns that overlap anthropogenic buffers. Of the total disturbance amounts, approximately 62% in the CCESA, 67% in the rut/ late fall range, and 65% in the winter range are attributable to burns. Though not directly applicable to barren-ground caribou, typically <35% total disturbance within the annual range of woodland caribou, as defined by ECCC (anthropogenic and natural), is an indication of a viable and self-sustaining population (Environment Canada 2011). Overall, the Project's net effect will likely result in a <1% disturbance increase relative to past conditions.

Finally, the amount of disturbed 'selected' habitat within the PCH's rut/ late fall and winter ranges is expected to be <1%. Only 0.2% or 76 km² (out of 42,417 km²) of 'selected' fall habitat is likely to be affected in the rut/ late fall range. Only 0.1% or 51 km² (out of 42,204 km²) of 'selected' winter habitat is likely to be

affected in the winter range. The Project is expected to produce a negligible net disturbance on 'selected' rut/ late fall (<0.1%) and winter (<0.1%) caribou habitat in those seasonal ranges.

A characterization of cumulative direct habitat and movement effects on caribou is provided in **Table 9-21.** The magnitude of cumulative direct habitat effects is expected to be Low to Moderate since surface disturbance and ECCC-defined disturbance within the CCESA are <1% and <19%, respectively. Cumulative effects at the seasonal range scales include surface disturbance up to 0.34% and ECCC-defined disturbance ≤27%. Most (>60%) of the ECCC-defined disturbances are attributable to burns <40-years old. There is certainty that these effects will occur and affect caribou habitat and movement across all geographic extents, which includes the PCH's annual range in Yukon (CCESA) and rut/ late fall and winter seasonal ranges. These cumulative effects may vary depending on where direct disturbance occurs (i.e., forested versus non-forested sites) but will be year-round and continuous. These cumulative effects are expected to be reversible for certain disturbances (e.g., mineral exploration and oil and gas) but not others with permanent human settlements and activities (i.e., communities).

Table 9-20. Eagle Plains Exploration Project Cumulative Effects Assessment of Direct Habitat and Movement Effects on Caribou from Present and Future Disturbances[1,2]

Cumulative Effect Indicator	Scenario	Caribou Cumulative Effects Study Area	Rut and Late Fall Seasonal Range	Winter Seasonal Range
Total Surface Disturbance (Footprints)	Present	285.6 km² (0.2%)	153.3 km² (0.2%)	148.4 km² (0.2%)
	Project	69.1–69.5 km² (0.1%)	69.1–69.5 km² (0.1%)	69.1–69.5 km² (0.1%)
	Future	2.2 km² (<0.1%)	2.2 km² (<0.1%)	2.2 km² (<0.1%)
	Total Cumulative Effect	356.9–357.3 km² (0.3%)	224.5–225.0 km² (0.3%)	219.3–219.7 km² (0.3%)
Total Disturbance to 'Selected' Habitat	Present	N/A	59.05 km² (0.1%)	39.59 km² (0.1%)
	Project	N/A	16.4–16.7 km² (<0.1%)	11.0–11.1 km² (<0.1%)
	Future	N/A	0.96 km² (<0.1%)	0.57 km² (<0.1%)
	Total Cumulative Effect	N/A	76.4–76.7 km² (0.2%)	51.2–51.3 km² (0.1%)
ECCC-Defined Disturbance (Anthropogenic 500 m Buffers + Fire)	Present	21,162.3 km² (18.0%)	19,485.4 km² (22.1%)	17,037.9 km² (26.2%)
	Project	570.7–570.8 km² (0.5%)	570.7–570.8 km² (0.7%)	570.7–570.8 km² (0.9%)
	Future	35.4 km²	35.4 km²	35.4 km²

Cumulative Effect Indicator	Scenario	Caribou Cumulative Effects Study Area	Rut and Late Fall Seasonal Range	Winter Seasonal Range
		(<0.1%)	(<0.1%)	(<0.1%)
	Total Cumulative Effect	21,768.4–21,768.5 km² (18.5%)	20,091.5–20,091.6 km² (22.8%)	17,633.5–17,633.6 km² (27.1%)

[1] Scales of analysis: Caribou Cumulative Effects Study Area = 117,820.6 km²; Rut and Late Fall Seasonal Range = 88,163.5 km²; Winter Seasonal Range = 65,075.8 km².

[2] The Net Project Effect refers to the increase in the cumulative effect indicator due to the Project.

Table 9-21. Characterization of Cumulative Direct Habitat and Movements Effects from the Eagle Plains Exploration Project on Caribou

Criterion		Rating	Rationale
Magnitude		Low to Moderate	The cumulative effect of total surface disturbance is expected to be Low (<1%) in magnitude across all spatial scales of assessment (CCESA, rut/ late fall and winter seasonal ranges). The Project is expected to increase total surface disturbance minimally relative to existing conditions (maximum 0.1% increase). The cumulative effect of direct disturbance to 'selected' caribou habitat is expected to be Low (<1%) in magnitude across all spatial scales of assessment. The Project is expected to have a negligible net disturbance effect on 'selected' rut/ late fall (<0.1%) and winter (<0.1%) caribou habitat in those seasonal ranges. The cumulative effect of ECCC-defined disturbance (fire and 500 m anthropogenic buffers) is expected to be Moderate (11–35%) in magnitude across all spatial scales of assessment. However, the Project is expected to increase total disturbance minimally relative to existing conditions (<1% increase).
Likelihood		Certain	The likelihood that the Project and existing projects and activities will cause habitat and movement effects is certain.
Geographic Extent		Caribou Cumulative Effects Study Area and Seasonal Range	Cumulative effects indicators span the PCH's rut/ late fall and winter range and the herd's annual range in Yukon (CCESA).
Duration, Frequency and Timing	Duration	Short-term to Long-term	The duration of cumulative direct habitats effects due to surface disturbance can range from short- to long-term depending on the disturbed site (non-forested versus forested).
	Frequency	Continuous	Vegetation clearing required for construction is infrequent, but the cumulative effect of this clearing on caribou can be continuous until vegetation regenerates.
	Timing	Year-round	Vegetation clearing required for construction is infrequent, but the cumulative effect of this clearing on caribou can occur year-round.

Criterion	Rating	Rationale
Reversibility	Reversible	Regeneration of vegetation along anthropogenic footprints are expected to occur, but the time required for complete regeneration will vary by feature. This effect is expected to be reversible for certain industries (e.g., mineral exploration, oil and gas) but not for others (e.g., permanent settlements and communities).

9.9.2.1 Context and Confidence

Determining cumulative direct habitat and movement effects on caribou considered the context of Regional Land Use Planning and the confidence in accurately quantifying and predicting those effects (**Table 9-22**). The effects characterization is consistent with the objectives of existing Land Use Plans, and there is relatively high confidence that effects were accurately captured in the assessment. It is possible that not all anthropogenic features on the landscape were captured to calculate the total level of disturbance, but there is a high degree of confidence that most disturbances were included. Furthermore, to provide a precautionary assessment of cumulative habitat effects, the effects of burns and 500 m buffers around all disturbance footprints were considered. Total disturbance within the PCH's annual and seasonal ranges were then calculated and compared against ECCC's 35% total disturbance threshold for woodland caribou (Environment Canada 2011), a subspecies that is likely more sensitive to vegetation clearing than barren-ground caribou. Therefore, the confidence in this cumulative effect assessment is high.

Table 9-22. Characterization of Context and Confidence in the Assessment of Cumulative Direct Habitat Effects on Caribou

Criterion	Rating	Rationale
Context	Conforms to Regional Land Use Plans	Land Management Unit IV zones of the North Yukon and Peel Regional Land Use Plans are areas zoned for the highest level of development. The Project activities are consistent with the integrated resource management objectives of the LUPs.
Confidence	High	There is high confidence in the characterization of cumulative effects and their persistence. A precautionary approach was taken to quantify direct habitat and movement effects.

9.9.3 Cumulative Indirect Mortality Effects

Cumulative indirect mortality effects result from linear features across the landscape, with higher linear feature densities (km/km²) potentially supporting facilitated predation of caribou by wolves and human hunters. Therefore, linear feature density was used to assess cumulative indirect mortality effects. Linear feature density was calculated as the total length of linear features divided by the size of the CCESA and PCH rut/ late fall and winter ranges.

A summary of the cumulative effect indicator for indirect mortality effects is provided in **Table 9-23**. Due to the Project, linear feature density is expected to increase by 0.2 km/km² in the CCESA and up to 0.4 km/km² in the PCH's winter range relative to existing conditions. The increase in linear feature density occurs due to the Project contributing approximately 25,000 km of additional linear features. As a percentage, this

equates to an approximate 160% increase in the CCESA, 170% increase in the rut/ late fall range, and 180% increase in the winter range.

These estimates are highly conservative because linear feature densities are not estimated by line type. Most of the linear features created by the Project are comprised of 3D LIS lines, which are unlikely to improve the travel and sightlines of predators and hunters (**Appendix 9-B**). Therefore, 3D LIS lines are expected to contribute minimally to facilitated predation of caribou.

A characterization of cumulative indirect mortality effects on caribou is provided in **Table 9-24**. The magnitude of cumulative indirect mortality effects is expected to be Low since the overall linear feature density is below the 'cautionary' indicator for land use planning (<0.75 km/km²). The Project's net effect also results in <0.4 km/km² additional linear feature density. At the broadest scale of analysis (CCESA), the total linear feature density is 0.4 km/km². Most of these linear features will be 3D LIS lines confined to the Project's RSA, which are unlikely to affect the PCH's broader annual and seasonal ranges. As discussed in **Section 9.6.6 Residual Indirect Mortality Effects**, even with increased potential for facilitated predation (due to higher linear feature density), the functional response by predators is expected to be relatively low within the PCH's range. Cumulative indirect mortality effects will mostly be during winter if packed snow on linear features increases the efficiency of predator/hunter movements. The effect will likely be irregular and seasonal (throughout winter) depending on caribou and predator/hunter use of linear features. The potential for effects outside of winter is unlikely (but not impossible) because ease of travel and sightlines are limited along 3D LIS lines due to narrow widths, curves/bends, and limited connectivity to roads (**Appendix 9-B**; also see **Section 9.5.4 Seismic Operations**). Overall, cumulative indirect mortality effects are expected to be reversible: (a) by limiting the spatial extent of linear features with packed snow (e.g., mostly confined to annual work areas for the Project), and (b) over time, due to vegetation regeneration along linear features.

Table 9-23. Characterization of Cumulative Indirect Mortality Effects from the Eagle Plains Exploration Project on Caribou from Present and Future Disturbances[1,2]

Cumulative Effect Indicator	Condition	Caribou Cumulative Effects Study Area	Rut and Late Fall Seasonal Range	Winter Seasonal Range
Linear Feature Density	Present	0.1 km/km² (16,785.6 km)	0.2 km/km² (15,078.2 km)	0.2 km/km² (14,636.8 km)
	Project	0.2 km/km² (25,031.7–25,091.7 km)	0.3 km/km² (25,031.8–25,091.7 km)	0.4 km/km² (25,031.8–25,091.7 km)
	Future	<0.1 km/km² (145.4 km)	<0.1 km/km² (145.4 km)	<0.1 km/km² (145.4 km)
	Total Cumulative Effect	0.4 km/km² (41,962.7–42,022.7 km)	0.5 km/km² (40,255.3–40,315.2 km)	0.6 km/km² (39,787.4–39,847.4 km)

1 Scales of analysis: Caribou Cumulative Effects Study Area = 117,820.6 km²; Rut and Late Fall Seasonal Range = 88,163.5 km²; Winter Seasonal Range = 65,075.8 km².

2 The Net Project Effect refers to the increase in the cumulative effect indicator due to the Project.

Table 9-24. Characterization of Cumulative Indirect Mortality Effects from the Eagle Plains Exploration Project on Caribou

Criterion		Rating	Rationale
Magnitude		Low	The increase in linear feature density due to the Project is expected to be High in magnitude (>100%). However, the maximum total linear feature density is <0.75 km/km², the 'cautionary' indicator for land use planning. Increased risk of facilitated predation of caribou by wolves and hunters is more likely at the local scale, proximate to the Project. Thus, the overall magnitude of the effect on PCH caribou across their annual (0.4 km/ km²) and seasonal ranges (0.5–0.6 km/km²) is expected to be Low.
Likelihood		Probable	The likelihood of cumulative indirect mortality effects on caribou is probable, but it is unclear to what extent this would affect caribou within their annual and seasonal ranges.
Geographic Extent		Caribou Cumulative Effects Study Area and Seasonal Ranges	The cumulative effect indicator spans the PCH's rut/ late fall and winter range and the herd's annual range in Yukon (CCESA).
Duration, Frequency and Timing	Duration	Short-term	Indirect mortality effects are mostly isolated to winter when packed linear features facilitate the movement/ travel of predators and hunters. Effects are expected to be relatively limited during other times of the year.
	Frequency	Irregular	Within a given year, conditions that could lead to indirect mortality will persist along snow-packed linear features. However, the frequency is irregular and dependent on caribou occurrence on linear features.
	Timing	Seasonal	Within a given year, conditions that could lead to indirect mortality are mostly limited to winter. Sightlines and ease of travel are unlikely to be improved for predators/hunters during other seasons, but not impossible.
Reversibility		Reversible	Effects of indirect mortality are reversible. Due to human travel, cumulative effects are expected to be limited to packed snow linear features. Effects are expected to be reversible when activity along linear features is stopped and snow remains unpacked, limiting predators' ability to move efficiently along those features. Regeneration of linear features over time will reduce effectiveness of linear features for predator/hunter travel.

9.9.3.1 Context and Confidence

Determining cumulative direct habitat and movement effects on caribou considered the context of Regional Land Use Planning and the confidence in accurately quantifying and predicting those effects (**Table 9-25**). The effects characterization is consistent with the objectives of existing Land Use Plans, and there is relatively high confidence that the effects were accurately captured in the assessment. Though there is a substantial increase in linear feature density at all scales (CCESA and seasonal ranges), the effects are mostly isolated to the RSA. Furthermore, even with a relatively high predicted functional response by wolves (see **Section 9.6.6 Residual Indirect Mortality Effects**), there would only be a small effect on the PCH's

overall mortality rate due to predation. Therefore, the confidence in this cumulative effect assessment is high.

Table 9-25. Characterization of Context and Confidence in the Assessment of Cumulative Effects on Caribou

Criterion	Rating	Rationale
Context	Conforms to Regional Land Use Plans	Land Management Unit IV zones of the North Yukon and Peel Regional Land Use Plans are areas zoned for the highest level of development. The Project activities are consistent with the integrated resource management objectives of the LUPs.
Confidence	High	There is high confidence in the characterization of cumulative effects and their persistence. Though a substantial increase in linear feature density is evident, it is mainly confined to the Project RSA, and the functional response by wolves is unlikely to have a population-level effect.

10 HERITAGE RESOURCES

Heritage Resources were selected as a key Valued Environmental and Socio-Economic Component (VESEC) for the Project because of their cultural value. Heritage Resources include archaeological, historic, and palaeontological resources. As of February 2024, eight archaeological sites (LlVc-1, LlVd-1, MaVc-4, MaVc-5, MaVc-6, MaVe-1, MbVf-1, and McVd-1) and one Yukon Historic Sites Inventory site (116I/03/001 - Tth'an Dhidlii Njik Dalgish Creek Resource Area) have been recorded within the Regional Study Area (RSA). No palaeontological sites have been recorded within the RSA. Given the size of the RSA, this is considered to be a very low site density, and additional currently undocumented Heritage Resource sites are very likely to be present. See **Appendix 10-A Heritage Resource Overview Assessment: Eagle Plains Basin Exploration Project, Appendix 10-B Heritage Resource Impact Assessment: Eagle Plains Exploration Project 2022 Final Report (22-22ASR),** and **Appendix 10-C Heritage Resource Impact Assessment: Eagle Plains Exploration Project 2023 Interim Report (23-03ASR).**

10.1 ASSESSMENT INDICATORS AND ASSESSMENT PARAMETERS

Indicators related to Heritage Resources include known Heritage Resource sites, identified areas of potential for currently undocumented Heritage Resource sites within the RSA, and chance finds of Heritage Resources in areas not associated with known sites or identified areas of potential for currently undocumented archaeological and historic sites. These indicators were selected to support protection of known sites and areas of potential for undocumented sites from being adversely affected by Project activities, to comply with the cultural values of people who utilize the RSA, and to adhere to applicable legislation (Government of Canada 1993; Yukon Government 2002, 2003a, 2003b). The assessment parameter used to evaluate effects on these key indicators is whether or not the Project has caused a qualitative change to the nature or condition of each of the three indicators.

10.2 PROJECT INTERACTIONS AND POTENTIAL EFFECTS

10.2.1 Interactions Table

The potential interactions between Heritage Resources and the Project are primarily related to activities that require ground disturbance. Such ground-disturbing activities have the potential to disturb both known Heritage Resource sites and currently unknown sites that may be present within the Project footprint. The potential for Project activities to interact with the Heritage Resources VESEC is summarized in **Table 10-1**, and the specific potential effects are summarized in **Sections 10.2.2, 10.2.3,** and **10.2.4.**

Table 10-1. Expected Interactions Between the Heritage Resources Valued Environmental and Socio-Economic Component and Project Activities, by Type of Potential Effect

Project Component / Activity	Disturbance of Known Heritage Resource Site	Disturbance of an Unassessed Area of Potential for Currently Unknown Heritage Resource Sites
Engagement	0	0
Main Camp Development and Operation, including Central Processing Facility (CPF)	2	2

Project Component / Activity	Disturbance of Known Heritage Resource Site	Disturbance of an Unassessed Area of Potential for Currently Unknown Heritage Resource Sites
Secondary Camp Development and Operation	2	2
Well Site Development	2	2
Well Testing	0	0
Winter Road Construction	0	0
Water Withdrawal	0	0
Seismic Line Construction	2	2
Seismic Testing	2	2
Drilling	2	2
Well Testing	0	0
Airstrip Construction	2	2
Airstrip Operation	0	0
Vehicle Traffic	0	0
Well Site Abandonment and Reclamation	2	2
Mix Bury Cover (MBC) Sump Site Development and Reclamation	2	2

10.2.2 Disturbance of a Heritage Resources Site

This effect applies to both known Heritage Resource sites and Heritage Resource sites that are currently undocumented. Disturbance here is defined as any activity that damages Heritage Resource materials (e.g., archaeological artifacts, historic structures, fossils) or alters the depositional context of a Heritage Resource site (e.g., alters the spatial relationships between the materials that make up an archaeological site) in an uncontrolled fashion that diminishes the interpretive value of the material culture at the site.

Disturbance of a known Heritage Resources site could occur during any Project activities that could directly affect the ground. This may occur during drilling operations, Mix Bury Cover (MBC) construction/excavation, Central Processing Facility (CPF) construction, secondary camp development, airstrip development, and well site abandonment and reclamation.

The confirmed Project footprints (e.g., Chance camp, MBC sump, winter access roads) do not currently overlap known Heritage Resources sites, and thus no effect is expected as a result of these Project footprints. Currently undefined Project footprints, including well sites and well spur roads, have the potential to affect known Heritage Resource sites.

10.2.3 Disturbance of an Unassessed Area of Potential for Currently Unknown Heritage Resource Sites

Disturbance here is defined as any ground disturbance within an identified area of potential for currently unknown Heritage Resource sites that occurs prior to the assessment of the area of potential by a Heritage Resource management professional.

Disturbance of a known Heritage Resources site could occur during any Project activities that could directly affect the ground. This may occur during drilling operations, MBC construction/excavation, CPF construction, secondary camp development, airstrip development, and well site abandonment and reclamation.

Most confirmed Project footprints (e.g., Chance Camp, MBC sump) do not currently overlap with unassessed areas of potential for currently unknown Heritage Resource sites, and thus no effect is expected as a result of these Project footprints. Winter access roads do have some overlap with untested areas of potential, but effects are expected to be minimal due to the low risk of ground disturbance of the winter road construction methodology. Currently undefined Project footprints, including well sites and well spur roads, have the potential to affect unassessed areas of potential for currently unknown Heritage Resource sites.

10.3 MITIGATION MEASURES

The primary mitigation measures Chance will use to control potential effects to Heritage Resources within the RSA are avoidance of known Heritage Resource sites and potential Heritage Resource sites using the results from a combination of a Heritage Resource Overview Assessment (HROA) and Heritage Resource Impact Assessment (HRIA). An HROA covering the RSA was completed in 2022 (Bennett 2022). This study was conducted to establish the initial baseline conditions with regard to Heritage Resources by identifying all known Heritage Resources within the RSA and developing a model mapping areas of high potential for currently unknown Heritage Resource sites. Specific HROA tasks included:

- a desktop review of the physical/environmental setting of the study area including biogeoclimatic zones, physiography, hydrology, bedrock and surficial geology, and vegetation and wildlife distributions;
- a desktop review of the cultural/historical setting of the study area including a review of the Precontact, Protohistoric, and Historic eras, as well as modern First Nations with traditional territories that overlap with the RSA (Vuntut Gwitchin First Nation, Tetlit Gwich'in First Nation, and First Nation of Na-Cho Nyak Dun);
- consultation with the Yukon Government Heritage Resource Unit to identify any relevant known heritage resource sites and/or studies in the vicinity of the study areas;
- a detailed review of specific landforms within the study area to identify specific areas of elevated heritage resource potential that should be investigated further via archaeological field assessment before any ground disturbance is conducted within them; and,
- Project-specific recommendations for the ongoing management of heritage resources within the study area.

This methodology is commonly used in cultural resource management and is designed to err on the side of caution by identifying areas of potential concern before the commencement of any ground disturbing activities.

HRIA studies represent the first stage of fieldwork aimed at ground truthing and testing the predicted areas of potential from the HROA. To date, eight phases of HRIA work have been conducted in relation to the Project and its previous iterations, including the two most recent phases that were commissioned by Chance (see Hammer 2000, 2002; Heffner 2007; Commisso and Heffner 2008; Buchanan and Gallagher 2013; Buchanan 2014; Bennett 2023, 2024), but much of the RSA remains unassessed at this time.

Chance will continue to sponsor additional phases of HRIA work as their exploration plan expands into new parts of the RSA. These additional studies will be conducted under a Class 2 permit as defined by the *Archaeological Sites Regulation* (Yukon Government 2003a), and will seek to confirm the presence or absence of Heritage Resource sites within the HROA areas of potential. HRIA tasks will include:

- pedestrian survey throughout predicted areas of Heritage Resource potential to identify surficial Heritage Resources and areas of elevated subsurface Heritage Resource potential;
- shovel testing in areas with substantiated potential for subsurface Heritage Resources;
- in-field documentation of all Heritage Resource sites encountered during the HRIA; and,
- reporting of all documented Heritage Resource sites encountered during the HRIA to the Proponent, the Yukon Government Heritage Resource Unit, and First Nations. Interim and final reports, site forms, and artifact curation preparations will meet the Yukon Archaeological Sites Regulations Guidelines for Permit Holders (Yukon Government 2020). These reports will include recommendations for the ongoing management of all documented Heritage Resource sites encountered during the HRIA.

If Heritage Resource sites are identified during an HRIA, the site area will be delineated, and a 30-metre (m) avoidance buffer, within which no ground disturbing work is allowed to occur without the application of additional mitigation measures (see following paragraph), will be applied as required by Yukon Land Use Regulation YOIC 2003/51 (Yukon Government 2003b). As such, each new phase of HRIA work updates the baseline conditions that the Project must consider while developing Environmental Constraints Mapping and planning future infrastructure (e.g., well pad placement, access road alignments, seismic send/receive lines, camp locations). The Project is committed to ensuring that all areas that will be affected by Project activities will be fully assessed by HRIA before ground-disturbing work commences. The HROA potential model will also be refined based on data obtained during HRIA work to improve its predictive ability (e.g., if a new Heritage Resource site is recorded in an unexpected location, similar locations with then be considered to have high potential for undocumented Heritage Resource sites).

As the primary mitigation measure for potential interactions between Project activities and known Heritage Resource sites, Chance will avoid the established site area and its 30-m avoidance buffer whenever possible. If avoidance is not feasible, then Chance will consider other mitigation measures. These mitigation measures would need to be developed by the proponent in conjunction with the Vuntut Gwitchin First Nation, Tetlit Gwich'in First Nation, and First Nation of Na-Cho Nyak Dun, as well as the Yukon Government Heritage Resource Unit. The most common form of these further mitigation measures is Systematic Data Recovery (SDR) excavation, conducted under a Class 2 permit as defined by the Yukon Government Archaeological Sites Regulation (Yukon Government 2003a), where controlled excavation of the site area

will be conducted to recover as much information about the site as possible before it is affected by Project activities. SDR tasks will generally include:

- initial shovel testing within the known site area to refine the site boundaries and identify clusters of subsurface Heritage Resources;
- excavation of 1 m x 1 m excavation units, placed as per the results of the shovel testing program as single units, trenches, and/or blocks, to recover a representative sample of cultural materials the site being mitigated;
- in-field documentation of all Heritage Resources encountered during the SDR program; and,
- reporting of all documented Heritage Resources encountered during the SDR program to the Proponent, the Yukon Government Heritage Resource Unit, and all First Nations whose traditional territory overlaps with the site area. Interim and final reports, site forms, and artifact curation preparations will meet the Yukon Archaeological Sites Regulations Guidelines for Permit Holders (Yukon Government 2020). These reports will include recommendations for the ongoing management of all documented Heritage Resource sites encountered during the SDR program.

To mitigate potential effects to unknown Heritage Resources sites, Chance will develop and implement a Chance Finds procedure as part of the Project Environmental Management Plan (EMP). The Chance Finds procedure will be communicated to all Project staff and contractors who will be working in the field where they may encounter unexpected Heritage Resources. This plan will lay out policies and procedures for how to proceed if chance finds are made. These policies and procedures will include the immediate cessation of work at the find site until contact can be made with the Yukon Government Heritage Resource Unit and First Nations heritage staff. The Proponent will then develop a plan in consultation with the Yukon Government Heritage Resource Unit and First Nations heritage staff for the ongoing management of the chance find site.

The potential adverse effects of not implementing these mitigation measures are presented in **Table 10-2.**

Table 10-2. Mitigation Measures

Mitigation Measure	Potential Adverse Effect
Avoidance of known Heritage Resources during Project design. Heritage Resources are prioritized for avoidance within the Environmental Constraints Mapping	Disturbance of a known Heritage Resources site.
Further assessment of known Heritage Resource Sites that cannot be avoided (e.g., systematic data recovery excavations).	Disturbance of a known Heritage Resources site.
Assessment of identified areas of potential for Heritage Resources through HRIA studies prior to the commencement of any ground disturbing Project activities.	Disturbance of a known Heritage Resources site; Disturbance of an unassessed area of potential for currently unknown Heritage Resource sites.
Establishment of a procedure for dealing with chance finds of Heritage Resources.	Disturbance of a known Heritage Resources site.

10.4 EFFECTS CHARACTERIZATION

10.4.1 Approach

Residual effects were assessed based on whether or not the Project is predicted to cause a qualitative change to the nature or condition of any Heritage Resources and/or areas of potential for unknown Heritage Resources, the importance of the Heritage Resources that are affected, and the significance of the adverse effects.

Criteria used for characterizing residual effects to Heritage Resources are defined in **Table 10-3**.

Table 10-3. Definitions of Effects Criteria Classifications for the Assessment of Heritage Resources

Criterion		Rating	Definition
Magnitude		Negligible	There will be no measurable change from existing conditions
		Low	The residual effect will be a slight, but measurable change from existing conditions (e.g., an incursion onto the avoidance buffer surrounding a Heritage Resource site)
		Moderate	The residual effect will be a measurable change from existing conditions, but will not affect the VESECs viability, role, or function (e.g., a minor disturbance to a portion of a Heritage Resource site)
		High	The residual effect will be a substantial, measurable change from existing conditions that may affect the VESECs viability, role, or function (e.g., a major disturbance or the complete destruction of a Heritage Resource site)
Likelihood		Unlikely	No residual effect is expected, but a residual effect is not impossible
		Possible	A residual effect may occur, but is not likely
		Probable	A residual effect is likely to occur, but it is not certain
		Certain	A residual effect will occur
Geographic Extent		Maximum disturbance footprint	The residual effect will be confined to the maximum disturbance footprint
		Local	The residual effect will be confined to the Local Study Area
		Regional	The residual effect will extend beyond the Local Study Area, but be confined to within the regional study area
		Beyond regional	The residual effect will extend beyond the Regional Study Area
Duration, Frequency and Timing	Duration	Short-term	The residual effect will occur for less than one year
		Medium-term	The residual effect will occur for greater than one year and up to the life of the Project
		Long-term	The residual effect will extend beyond the life of the Project
		Permanent	The residual effect is predicted to be permanent and thus unlikely to recover to existing conditions

Criterion		Rating	Definition
	Frequency	Occasional	The residual effect will occur rarely (once or a few times over the life of the Project)
		Periodic	The residual effect will occur consistently at regular intervals or associated with temporal events (e.g., during periods of ground-disturbing work)
		Continuous	The residual effect will occur continuously
	Timing	Year-round	The residual effect will occur year-round
		Seasonal	The residual effect will be confined to a portion of the year
Reversibility		Reversible	The residual effect is predicted to be reversible within a clearly defined period
		Irreversible	The residual effect is predicted to be irreversible

10.4.2 Residual Effect

If the mitigation measures described in **Section 10.3** are followed, there should be negligible adverse residual effects resulting from the Project. The one case where an adverse residual effect may occur is if SDR excavations are required at a Heritage Resource site. In this case, the site will have been permanently removed from the landscape. However, the SDR work will provide a much more detailed understanding of the excavated site compared to what we know about sites that were avoided completely, so the adverse effect brings with it a positive effect to our understanding of Heritage Resources within the Project footprint.

The residual effects of adverse effects to Heritage Resource sites are summarized in **Table 10-4**.

Table 10-4. Residual Effects Characterization

Criterion		Rating	Rationale
Magnitude		Negligible	Mitigation measures are expected to prevent/minimize any Project-related adverse residual effects to Heritage Resource sites to the point where there are no measurable effects predicted
Likelihood		Unlikely	Mitigation measures are expected to prevent/minimize any Project-related adverse residual effects to Heritage Resource sites
Geographic Extent		Maximum disturbance footprint	Adverse residual effects will not extend beyond the Project footprint of the Project component that will affect a Heritage Resource site
Duration, Frequency and Timing	Duration	Permanent	Once adversely affected, a Heritage Resource site cannot be restored to its original condition
	Frequency	Occasional	Mitigation measures are expected to prevent/minimize any Project-related adverse residual effects to Heritage Resource sites
	Timing	Year-round	Once incurred, adverse residual effects to Heritage Resources are continuous

Criterion	Rating	Rationale
Reversibility	Irreversible	Once adversely affected, a Heritage Resource site cannot be restored to its original condition

10.4.2.1 Context and Confidence

The confidence of no residual adverse effect anticipated is high with regard to Heritage Resources within the highest development for the Project (**Table 10-5**).

Table 10-5. Rating and Rationale for Context and Confidence

Criterion	Rating	Rationale
Context	Highest Development	The RSA is within Land Management Unit IV zones of the North Yukon and Peel Regional Land Use Plans (LUPs), which are areas zoned for the highest level of development. The Project activities are consistent with the integrated resource management objectives of the LUPs
Confidence	High	The RSA has not been thoroughly studied with reference to Heritage Resources, but the indicators, assessment parameters, and mitigation measures have been applied with great success on other projects throughout western Canada and beyond

10.5 SIGNIFICANCE

The predicted residual effects for Heritage Resources were assessed for their significance as part of the Project assessment. **Table 10-6** provides definitions for significant and not significant.

Table 10-6. Determination of Significance

Characterization	Definition
Not Significant	Effects to Heritage Resources that occur as part of a mitigation measure (e.g., SDR excavations)
Significant	Adverse effects to Heritage Resources that occur in the absence of the mitigation measures presented above

A significant adverse residual effect on Heritage Resources is one that results in a permanent Project-related disturbance to, or destruction of, all or part of a Heritage Resource that is considered to be of major importance due to factors such as rarity, condition, cultural significance, or opportunities for research, and that cannot be mitigated or compensated. The implementation of mitigation is a key element of this significance criterion. Therefore, in consideration of the above discussion, the significance threshold, the mitigation that has been implemented to date, and the mitigation that will be implemented as the Project moves forward, the residual effects of the Project on Heritage Resources for all phases of the Project are rated **not significant**.

10.6 CUMULATIVE EFFECTS ASSESSMENT

Given that residual effects of the Project on Heritage Resources were predicted to be **negligible**, an assessment of cumulative effects on Heritage Resources was not conducted.

11 SOCIO-ECONOMICS

This section describes and summarizes the assessment of potential effects of the Project on the human environment related to social, economic, health, and culture conditions. The assessment follows the general methodological approach and concepts described in **Section 3 Methods**. Specific methods for socio-economic assessment are provided here, as well as assessment findings. Assessment findings include identification of Project interactions and effects, proposed approaches to mitigation to reduce and manage potential socio-economic impacts, characterization of residual Project and cumulative effects, and determination of significance. Monitoring and follow-up programs to assess effectiveness of mitigation measures and unforeseen Project-related effects are also described where appropriate.

The Valued Environmental and Socio-Economic Component (VESECs) identified for the socio-economic assessment and the rationale for their selection are provided in **Table 3-1** in **Section 3 Methods**. Identified Socio-economic VESECs consist of:

- Land and Resource Use: assesses the Project effects to commercial, recreation, and traditional land and resource use;
- Community Infrastructure and Services: assesses the Project effects on community related infrastructure and services;
- Employment and Economy: assesses the Project effects to labour, goods and services, employment and business opportunities, and the regional or local economy; and,
- Community Health and Wellbeing: assesses the Project effects on the health and wellbeing of the communities in the vicinity of the Project.

The indicators and parameters used for determining a Project-related change to Socio-economic VESECs are presented in **Table 3-2** in **Section 3 Methods**.

Spatial boundaries related to Socio-economic VESECs are presented in **Table 11-1.** Each socio-economic VESEC detailed in the following sections will include specific technical and administrative boundaries, and data limitations that apply to the analysis provided (see **Section 11.1.1. Methods: Assessment Boundaries**).

The socio-economics assessment is informed by the following related VESEC assessments:

- Permafrost and Terrain (**Section 4**);
- Water Resources (**Section 5**);
- Fish and Fish Habitat (**Section 6**)
- Vegetation (**Section 7**)
- Wildlife and Wildlife Habitat (**Section 8**); and,
- Caribou (**Section 9**).

Any assessment boundaries or limitations related to these related VESECs will be inherent in the analysis provided in the socio-economic assessment.

11.1 METHODS

The scope of the Socio-economic VESECs was developed based on *Yukon Environmental Socio-economic Assessment Act, S.C. 2003, c. 7* (*YESAA*) requirements (Section 50(3)) to identify and select environmental and socio-economic components, including components identified by First Nations and communities that may be affected by Project-related activities and/or may experience significant adverse environmental effects. Consistent with *YESAA* requirements, the scope of this socio-economic assessment was based on an understanding of the Project-related components and activities, issues and concerns identified by First Nations and local communities gathered through ongoing consultation and engagement since 2015, and through consideration of existing environmental and socio-economic conditions.

Selected methods used in the socio-economic assessment align with established guidance for environmental and socio-economic assessment process in the Yukon, federal guidance from Impact Assessment Agency of Canada (IAAC), and best practice for socio-economic assessment practice (Impact Assessment Agency of Canada 2023; Yukon Environmental and Socio-economic Assessment Board 2021).

11.1.1 Assessment Boundaries

11.1.1.1 Spatial Boundaries

The spatial boundaries identified for the Socio-economic VESECs vary from those identified for the biophysical VESECs in **Table 3-3** in **Section 3 Methods**. **Table 11-1** presents the Local Study Area (LSA) and Regional Study Area (RSA) boundaries for each Socio-economic VESEC.

Table 11-1. Socio-economic Spatial Boundaries

VESEC	Spatial Boundary	
	Local Study Area	**Regional Study Area**
Land and Resource Use	Project footprint (including access roads) plus a 500 m buffer where the Project may potentially directly affect land use or access and/or users may experience a sensory disturbance.	Game Management Subzones overlapping the Project footprint where the Project could affect regional management of wildlife and harvesting.
Employment and Economy	The LSA and RSA for the Employment and Economy subcomponent include the boundaries of the regional government and municipalities from which the Project could potentially source business services and labour. Includes the following communities: • Whitehorse • Old Crow • Fort McPherson (NWT) • Dawson City • Village of Mayo	
Community Infrastructure and Services	The LSA for the Community Infrastructure and Services subcomponent consists of the local government and municipality of Dawson City, from which the Project may directly source community	The RSA for the Community Infrastructure and Services subcomponent includes the boundaries of the regional government and municipalities from which the Project may potentially source municipal services and infrastructure and related regional public transportation networks.

VESEC	Spatial Boundary	
	Local Study Area	Regional Study Area
	services and infrastructure, and the Dempster Highway, which is the main public roadway accessing the Project.	This boundary includes the following communities: Whitehorse Old Crow Fort McPherson (NWT) Village of Mayo
Community Health and Wellbeing	The LSA for the Community Health and Wellbeing - Environmental Determinants of Health subcomponents consist of the Project footprint (including access roads), plus a 500 m buffer where the Project may directly affect land use or access that would impact environmental determinants of human health.	The RSA for the Community Health and Wellbeing - Environmental Determinants of Health subcomponent consists of Game Management subzones overlapping the Project footprint where the Project could affect regional management and harvesting of wildlife in its relation to environmental determinants to human health outcomes.
	The LSA for the Community Health and Wellbeing - Social Determinants of Health subcomponents consists of the local government and municipality of Dawson City, from which the Project may directly source health services and social services related to wellbeing.	The RSA for the Community Health and Wellbeing - Social Determinants of Health subcomponents includes the boundaries of the regional government and municipalities from which the Project may potentially source community health and social services related to wellbeing. This boundary includes the following communities: • Whitehorse • Old Crow • Fort McPherson (NWT) • Village of Mayo

Notes: LSA = Local Study Area; RSA = Regional Study Area; NWT = Northwest Territories; m = metres

These boundaries include consideration of the overlapping Traditional Territories of the following First Nations:

- Vuntut Gwitchin First Nation;
- Na-Cho Nyäk Dun First Nation;
- Tetłʼit Gwichʼin Council;
- Gwichʼin Tribal Council; and,
- Trʼondëk Hwëchʼin First Nation.

11.1.1.2 Temporal Boundaries

As stated in **Section 3.1.1.4.2 Temporal Boundaries**, the Project will be conducted in one phase to take place over approximately 10 years, with all Project activities (e.g., infrastructure/well development, drilling, testing, reclamation) occurring somewhat concurrently during this period. Temporal boundaries related to Socio-economic VESECs for specific Project activities and design features include:

- Construction activities for the Central Processing Facility (CPF) and other facilities at the Chance Camp (e.g., air strip, water reservoir, aviation fuel storage) are anticipated to be temporary (e.g., up to 1 year) and occur as an early construction period of the total 10-year temporal boundary.
- If required, temporary use of the Eagle Plains Hotel for personnel overflow accommodation is anticipated to be infrequent and for short periods (e.g., up to 3 months) and primarily during the winter months.

11.1.1.3 Technical Boundaries

Technical boundaries are the constraints imposed on the assessment by limitations in the ability to predict or measure potential effects of the Project (e.g., unavoidable data gaps or model limitations). Technical boundaries related to Socio-economic VESECs include:

- The locations of well sites are not certain at the time of the assessment due to the exploratory nature of the Project. As a result, the evaluation of potential effects on specific area use and access within the Project footprint considered constraints analysis to focus the analysis on potential areas of interaction.
- The analysis and prediction of socio-economic effects depends on the technical boundaries of related VESECs. This includes available information and analysis related to fish and fish habitat, wildlife and wildlife habitat, caribou, vegetation, soils, geology, soils, and permafrost, and water resources. This also includes limited technical information related to air quality, noise and vibration, lighting, and visual quality. Where technical information was limited, the analysis and prediction of socio-economic effects was based on conservative, industry-standard information and reasonable professional judgment.
- Assessment of the effects on land and resource use related to cultural use, recreation and tourism, hunting, and trapping depend on the details of information regarding when, where and how use and access occurs in the LSA. While there is confidence that information presented in this socio-economic assessment is appropriate to characterize general patterns of land and resource use and predict potential effects in the LSA, detailed knowledge of the specific locations and periods or patterns of use is less certain. As a result, there are limits for interpreting existing conditions and future levels of use related to cultural use, recreation and tourism, hunting, and trapping in the LSA.

The assessment addresses remaining technical boundaries by taking a precautionary and conservative approach to identifying interactions and Project effects based on an understanding of existing socio-economic conditions within the LSA and RSA, professional knowledge and experience.

11.1.1.3.1 Data Limitations

- Publicly available information on potentially affected First Nations and communities is limited. Information available from sources including Statistics Canada, Yukon Bureau of Statistics, Northwest Territories (NWT) Bureau of Statistics, Crown-Indigenous Relations and Northern Affairs Canada (CIRNAC) and Indigenous community websites has been included where available. Primary data collection to confirm demographic patterns has been conducted. Census data are also typically limited for smaller communities due to confidentiality concerns and suppression of data. While this information is not a comprehensive representation of the

identified First Nation communities, it is sufficient to characterize existing conditions and predict potential socio-economic effects.

- No primary Traditional Knowledge information was collected for this assessment. Sources of Traditional Knowledge were limited to publicly available secondary sources. **Section 11.1.3.4 Traditional Knowledge** summarizes how Traditional Knowledge was collected and applied to this assessment.
- The primary data collection program was focused on members of the Gwich'in Tribal Council and Vuntut Gwitchin First Nation government services and related administration within the communities of Old Crow, Fort McPherson, and Inuvik. These First Nations communities represent key centres that may be affected by the Project and First Nations whose traditional use areas would most directly overlap the Project. The other First Nations of First Nation of Na-Cho Nyäk Dun, Tr'ondëk Hwëch'in First Nation and residents of Aklavik, Dawson City, Mayo and Tsiigehtchic were consulted more broadly on the Project but were not involved in socio-economic primary data collection.
- Limited traffic count information was available for the portion of the Dempster Highway in the Yukon. The interpretation of 2011 Yukon Traffic Count Survey and 2019 NWT traffic report for the Dempster Highway in the NWT was used to address this limitation and to characterize traffic on the Dempster and Klondike Highways for the purposes of this assessment.
- Detailed information was not available related to motor vehicle accidents and safety. General information on injuries and fatalities from motor vehicle collisions in the Yukon from a 2019 study was used to characterize regional safety concerns related to traffic within the LSA and RSA.
- Information on municipal infrastructure was limited to publicly available information from Yukon Government, Yukon Energy Corporation, and community websites. This information was confirmed and supplemented by information gathered during informational interviews as part of the socio-economic primary data collection program.
- Statistical information for small communities is often limited or intentionally suppressed by the Yukon Bureau of Statistics, NWT Bureau of Statistics, and Statistics Canada to safeguard the confidentiality of personal information. As a result, statistical information typically available for large communities is not available for smaller communities. This is often seen for unincorporated communities and communities with small populations. In addition, direct comparison between data sources and time periods can be problematic due to differences in geographical and statistical reporting units.
- Detailed information regarding the Project's labour and procurement requirements for each of the proposed activities/components was not available.
- Detailed information regarding the expected Project capital spending in goods and services for the communities situated within the LSA and RSA was not available.
- Detailed information regarding the goods and services offered by the businesses located within the LSA and RSA was not publicly available.

11.1.1.4 Administrative Boundaries

Administrative boundaries refer to the limitations imposed due to political, social, and economic constraints (e.g., municipal boundaries, First Nations community boundaries). These may represent the extents of management areas or information collected as part of regional or provincial surveys that are not the same

as the spatial boundaries of the socio-economic VESECs and could influence the assessment of the Project effects. Administrative boundaries identified in relation to socio-economic VESECs include:

- Municipal or community boundaries are the jurisdictional areas for management of municipal services, as well as administrative boundaries for population and economic data analysis and reporting.
- Within the Yukon, Settlement Lands are the parcels of land, identified in each First Nation's Final Agreement, that are owned and managed by a First Nation and represent the administrative boundaries for the purposes of First Nations land planning and development activities. As a result, Settlement Lands are typically the focus of detailed information and management planning rather than the broader Traditional Territories which represent a larger area of cultural use by First Nations members.
- Game Management Zones are administrative areas established for managing the harvest of wildlife species. Data for big game harvesting is reported for overlapping game management zones which may be larger than the area of the LSA resulting in limits for interpreting existing conditions. However, it is expected that patterns shown by big game harvesting data will be generally indicative of patterns in the LSA.
- Trapping Concessions are areas for which one or more licensed trappers is granted exclusive rights for the trapping of fur bearing animals. Data for furbearer harvesting is reported for whole concession areas which may be larger than the area of the LSA and may not represent actual areas actively accessed for trapping. It is expected that trapping patterns shown by the data will be generally indicative of patterns in the LSA.

11.1.2 Input from Engagement

Chance is required to meet consultation requirements under Sections 3 and 50(3) of the *YESAA* (Government of Canada 2003). The *YESAA* requires Chance to consult with potentially affected First Nations and residents of communities prior to submitting the Project Proposal to the Executive Committee. Potentially affected First Nations and residents of communities that have been engaged on this Project to date include:

- Vuntut Gwitchin First Nation;
- First Nation of Na-Cho Nyäk Dun;
- Tr'ondëk Hwëch'in First Nation;
- Gwich'in Tribal Council and the Designated Gwich'in Organizations; and,
- Residents of Aklavik, Dawson City, Fort McPherson, Inuvik, Mayo, Old Crow, and Tsiigehtchic.

Details of the consultation and engagement process conducted for the Project are provided in **Section 2 Consultation and Engagement**.

Issues and concerns related to socio-economic conditions have been raised by First Nations and communities during past and ongoing consultation and engagement activities. A summary of the general Project-related socio-economic issues and concerns raised include:

- Cultural value of the Porcupine Caribou Herd and concern about their decline.
- Effects on wildlife behaviour and habitat that are valued as traditional food and for cultural and spiritual wellbeing.

- Concern about effects on traditional trails and traditional sites related to cultural use areas for trapping and hunting (i.e., moose and caribou).
- Increased access to traditional territories and resulting damage to the livelihood of First Nations residents.
- Interest in employment and contract opportunities.
- Concern over the capacity of local communities to meet the demand for employment opportunities without further training and funding.
- Effects on the potential visual aesthetics of the landscape.
- Concern about the human land use-related disturbances such as noise, smell, and light and potential mitigations.
- Concern related to increased traffic on the Dempster Highway.
- Opportunities for involvement in monitoring.
- Concerns about Project-related effects to climate change to the land and the wildlife on which Forst Nations depend for food, and ability of to travel and use the land for traditional purposes.
- Concern about potential for water contamination (used by land users while on the land).
- Concern for potential Project-related effects to water bodies and wetlands from new winter road and permafrost/terrain stability.
- Identifying that the landscape is a key cultural value for the First Nations.
- Concern about Project access roads and effects on water and fish.
- Concern over increased risk of increased skidoo traffic and access management.
- Comment highlighting the importance of upholding objectives from the North Yukon Regional Land Use Plan (NYRLUP).
- Comment requesting clarification on process for protecting oral history.
- Comment highlighting the issue of oil and gas exploration's effect on the quality of Traditional Territory and impact to the livelihood of First Nations.

These issues and concerns have informed the scoping of the socio-economic VESECs, the definition of study area boundaries, and the identification of Project interactions and effects. Further detail on the socio-economic related engagement input is provided in **Appendix 11-A Eagle Plains Exploration Project Socio-Economic Baseline Technical Data Report (TDR**).

11.1.3 Existing Conditions Data

11.1.3.1 Secondary Data Collection

A desktop review was conducted to gather information on existing demographic and socio-economic conditions. This included a review of publicly available data (including analysis of tabular and mapping data), the results of ongoing Project-related engagement and consultation activities, available traditional use information and studies, applications from other similar projects within the region, and the details of the Project design (**Section 1 Details of the Proposed Project**).

Publicly available secondary information included:

- Demographic data from Statistics Canada, Yukon Bureau of Statistics, and CIRNAC First Nation Profiles.

- Labour force, business, and economic data from the Yukon Business Survey, Statistics Canada, Yukon Bureau of Statistics, Indigenous Services Canada, CIRNAC, and local community websites.
- Local and regional land use planning documents from the Yukon Land Use Planning Council and local community websites.
- Information about land use tenure, licences, mining claims, game management, guide outfitting and registered traplines, parks and protected areas, and commercial resource development projects (e.g., forestry, oil and gas, mining) from the Yukon Government databases and GeoYukon mapping services.
- Community infrastructure and service information Yukon Health and Social Services, First Nations Regional Health Survey, Yukon Education and local community websites.
- Land use and health related information from the Yukon Government databases, the North Yukon Planning Commission, Indigenous Services Canada, CIRNAC, and local community websites.

A report assessing the environmental determinants of health for the Project was completed in November 2023 (Moher 2023). The report assessed the potential effects of Project activities on the environmental determinants of health for human receptors (people) in the LSA. To establish environmental risk pathways, the following components were evaluated through a desk-based assessment:

- environmental hazards (i.e., contaminant or stressor in the air, water, soil, or traditional foods);
- pathways of exposure (i.e., contaminant or stressor transported from its source to a human receptor); and,
- humans present within the area who could be exposed to contaminant or stressor.

The desktop assessment evaluated whether any Project activities present a complete risk pathway for exposure, consisting of an identified hazard, a pathway of exposure and a human that would be exposed. The evaluation considered the seasonality of Project activities as well as varying harvesting seasons that affect land users time on the land. Where complete pathways are determined, a risk to human health is possible. Additional assessment steps would be required to determine actual environmental determinants of health risks and characterize the scale of this risk, though limitations are noted in the assessment where applicable.

The assessment of social determinants of health was conducted according to the methods set out in **Section 3 Methods**. Further detail on socio-economic related secondary information collected for this assessment is provided in **Appendix 11-A**.

11.1.3.2 Primary Data Collection

Primary data collection with key informants was undertaken as a part of this assessment to confirm the findings from secondary data collection and to address identified data gaps. Building on available information from secondary sources, informational interviews were coordinated with representatives from First Nations and Yukon Territory government services, local administrators, and relevant land users such as commercial operators and recreation organizations. Both in-person interviews and virtual interviews were conducted with key informants to obtain information on the socio-economic conditions in the LSA and RSA including population demographics, traditional economy and First Nations cultural land use,

commercial and recreational land use, employment and contracting opportunities, community infrastructure and services, and community health and wellness.

Interviewees were selected based on their knowledge and expertise as representatives of communities and organizations. Individuals who were interviewed or provided data for this report included representatives from Vuntut Gwitchin First Nation/Old Crow and Gwich'in Tribal Council community services related to energy and community services, health and social services, land use, heritage and culture, natural resources, local Royal Canadian Mounted Police (RCMP), Yukon University, Chief Zzeh Gittlit School, Blackstone Outfitters, and the Yukon Snowmobile Association. Interviews with First Nations community representatives were conducted in accordance with relevant license agreements and protocols from the Gwich'in Social and Cultural Institute (GSCI) and Vuntut Gwitchin First Nation Heritage Department.

11.1.3.3 Disaggregating Data

The social context within a community is critical to understanding the issues that are important in that setting, and how these issues can contribute to potential Project-related interactions or effects. Where possible, collected data were disaggregated to capture information about the conditions of different sub-groups within the population of the LSA and RSA. This approach recognizes that socio-economic conditions in a community may be experienced differently by different people or groups, according to identity factors such as sex, gender, age, ethnicity, Indigeneity, and other unique characteristics. The research approach is aligned with the Canadian Gender-based Analysis Plus analytical process for the assessment of diverse groups (Government of Canada 2021).

11.1.3.4 Traditional Knowledge

For the preparation of this assessment, sources of Traditional Knowledge were limited to publicly available Traditional Knowledge studies or reports not specifically prepared for the Project Proposal; also known as secondary Traditional Knowledge. Secondary Traditional Knowledge was collected for Tr'ondëk Hwëch'in First Nation, First Nation of Na-Cho Nyäk Dun, Vuntut Gwitchin First Nation, and Tetl'it Gwich'in Council/Gwich'in Tribal Council. These included studies or reporting prepared for other projects or initiatives in the region (e.g., Dempster Highway Shoreline Stabilization Project, Michelle Creek Quartz Exploration), other First Nations-published Traditional Knowledge studies and documents (e.g., Traditional Knowledge policy documents, First Nations Land Use Planning documents, harvest studies), or reporting of environmental and/or First Nations cultural activities on traditional territories.

Permission for use of secondary sources of Traditional Knowledge was requested of Tr'ondëk Hwëch'in First Nation, First Nation Na-Cho Nyäk Dun, Vuntut Gwitchin First Nation, and Tetl'it Gwich'in Council/Gwich'in Tribal Council. Permission was only provided by Vuntut Gwitchin First Nation and Gwich'in Tribal Council. As a result, the Traditional Knowledge used in this assessment is limited to sources for which consent has been received. Secondary sources used in this assessment include:

- Vuntut Gwitchin First Nation materials related to Traditional Knowledge from the Vuntut Gwitchin Government Heritage Branch;
- Vuntut Gwitchin First Nation studies related to traditional harvests, and reporting on environmental monitoring of the Vuntut Gwitchin First Nation Traditional Territory;
- Mapping of Vuntut Gwitchin First Nation resource use and cultural use areas;
- The Gwitch'in Place Names Atlas and regional natural resource mapping;

- Gwich'in Tribal Council studies related to caribou harvesting from the Gwich'in Social and Cultural Institute/Gwich'in Renewable Resources Board, and the Gwich'in Harvest Study; and,
- Gwich'in Land Use Plan and zoning related to traditional/cultural activities in the Gwich'in Settlement Area.

Further detail on Traditional Knowledge studies or reports collected for this assessment is provided in **Appendix 11-A**.

11.1.4 Effects Assessment

The general methodology used to assess the potential adverse effects of the Project is provided in **Section 3 Methods**. A summary of the specific methodology as it relates to the assessment of Socio-economic VESECs is provided below.

11.1.4.1 Potential Project Interactions and Effects

Potential interactions between Project components or activities and Socio-economic VESECs were evaluated to identify pathways for potential socio-economic effects. In cases where a Project interaction is expected, preliminary consideration was given to the potential effect. In cases where no or negligible interaction was expected, the potential effect was not carried forward for further assessment. Interactions resulting in positive effects (e.g., local economic benefits) were described but not carried forward for further assessment. A rationale is provided describing the VESEC-specific interactions, the direction of effect and cases where no effect or negligible effects are expected.

For those Project interactions carried forward in the assessment, the potential adverse effects arising from those interactions were analyzed and described. This analysis draws on an understanding of the characteristics and interactions of the Project components or activities with the existing conditions of the affected Socio-economic VESECs, reviewed of similar VESEC assessments, and information from ongoing engagement and consultation.

11.1.4.2 Mitigation Measures

Mitigation measures are required to reduce, eliminate or control potential adverse socio-economic effects. Mitigation measures may include standard measures such as Best Management Practices (BMPs), protocols, policies and strategies. Mitigation will consider the input of First Nations and local communities gathered through ongoing engagement and consultation. Mitigation measures will be applied to socio-economic effects to further identify the potential for residual Project effects.

For the purposes of this assessment, management strategies to address potential effects included the Project design are summarized in this section as well.

11.1.4.3 Characterization of Residual Effects

Based on the effects classification presented in **Section 3.1.4 Effects Characterization**, definitions for residual effects classification criteria specific to Socio-economic VESECs are presented in **Table 11-2** below.

Table 11-2. Socio-economic Effects Criteria Classifications

Criterion		Rating	Definition
Magnitude		Negligible	There will be no measurable change from existing conditions, or a minor effect that will be adequately addressed by standard management measures and practices.
		Low	The residual effect will be a slight, but measurable change, not easily distinguished from existing conditions
		Moderate	The residual effect will be a measurable change from existing conditions but will not affect the VESECs viability, role or function
		High	The residual effect will be a substantial, measurable change from existing conditions that may affect the VESECs viability, role or function
Likelihood		Unlikely	No residual effect is expected, but a residual effect is not impossible
		Possible	A residual effect may occur but is not likely
		Probable	A residual effect is likely to occur, but it is not certain
		Certain	A residual effect will occur
Geographic Extent		Maximum disturbance footprint	The residual effect will be confined to the maximum disturbance footprint
		Local	The residual effect will be confined to the Local Study Area
		Regional	The residual effect will extend beyond the Local Study Area but be confined to within the regional study area
		Beyond regional	The residual effect will extend beyond the regional study area
Duration, Frequency and Timing	Duration	Short-term	The residual effect will occur for less than one year
		Medium-term	The residual effect will occur for greater than one year and up to the life of the Project
		Long-term	The residual effect will extend beyond the life of the Project
		Permanent	The residual effect is predicted to be permanent and thus unlikely to recover to existing conditions
	Frequency	Occasional	The residual effect will occur rarely (once or a few times over the life of the Project)
		Periodic	The residual effect will be occur consistently at regular intervals or associated with temporal events (e.g., during spring freshet, low flows, growing season)
		Continuous	The residual effect will occur continuously
	Timing	Year-round	The residual effect will occur year-round
		Seasonal	The residual effect will be confined to a portion of the year
Reversibility		Reversible	The residual effect is predicted to be reversible within a clearly defined period
		Irreversible	The residual effect is predicted to be irreversible

11.1.4.4 *Context and Confidence*

Limitations of existing data and uncertainty associated with the assessment as well as confidence estimates associated with the Project's residual effects were characterized by assigning according to the approach in **Section 3.1.4.3.1 Context and Confidence**.

11.1.4.5 Significance Determination

The determination of significance of potential residual effects for Socio-economic VESECs was based on consideration of the residual effects rating assigned, a review of contextual information, consultation with First Nations and local communities, and professional judgment. The significance of all residual effects are assessed collectively to determine the overall residual effect for each Socio-economic VESEC as significant, or not significant, based on the following definitions:

- **Significant**: Potential residual effects are considered significant if they are high magnitude at any duration or geographical extent. Adverse residual effects will also consider significance in relation to sensitive context and the likelihood of occurrence.
- **Not significant**: Potential residual effects determined to be not significant are those that result in a measurable change but do not meet the definition of significant.

11.1.4.6 Cumulative Effects

The assessment of cumulative effects on Socio-economic VESECs follows the methods outlined in **Section 3.1.6 Cumulative Effects**. The Cumulative Effects Assessment (CEA) was completed for all Socio-economic VESECs with predicted residual effects and considers the potential residual effects of the Project that may interact with the effects from other projects and activities listed in **Table 3-8** in **Section 3.1.6 Cumulative Effects**.

The historical context for Socio-economic VESECs provides an overview of past and present development and activities that have influenced the socio-economic conditions of the region (see **Appendix 11-A**). For the CEA of Socio-economic VESECs, past and present projects and activities whose status is listed as being complete were considered to be reflected within the existing conditions characterizations. Present projects and activities whose status is listed as being ongoing were further considered where they have the potential to result in additional activities that could interact with the residual effects of the Project and reasonably foreseeable future projects and activities. Cumulative effects analysis for Socio-economic VESECs also includes some context about the current and ongoing effects of climate change that may result in a cumulative effect during the 10-year life of the Project.

Cumulative effects were assessed within the respective RSA boundaries for each Socio-economic VESEC as identified in **Section 11.1 Methods**. These boundaries were selected because they provide a regional context for the assessment of Project effects, and to encompass the area within which the residual effects of the Project on Socio-economic VESECs have the potential to combine cumulatively with the effects of other projects and activities.

Potential cumulative effects were determined by comparing existing conditions (includes past and present) to predicted future conditions. All residual cumulative effects are characterized following the same methods as potential residual effects, as outlined in **Section 11.1.4.3 Characterization of Residual Effects**.

11.1.4.6.1 Potential Influences of Climate Change on Future Conditions

Potential climate change effects have the potential to directly or indirectly interact with Socio-economic VESECs. For example, climate change effects such as extreme weather events (e.g., flooding, wildfires, and periods of drought) or changes to seasonal weather norms can damage community infrastructure, disrupt land and resources use activities, and cause stress to affected people and communities' subsistence use of the land and resources. Climate change effects can also disproportionately affect more vulnerable members of the population.

Climate change effects are acknowledged as already contributing to the environmental quality of the Yukon, and these effects are expected to continue (Government of Yukon 2024). Climate changes effects that are expected to cumulatively interact with predicted adverse residual effects in the Socio-economic VESEC RSAs include:

- warming temperatures;
- an increase in average annual precipitation;
- permafrost thaw;
- extreme weather events;
- changes to snow, ice and water; and,
- changes to vegetation and wildlife (Perrin and Jolkowski 2022).

Potential climate change effects that could cumulatively interact with Project residual effects during the 10-year life of the Project and result in a meaningful change within that timeframe will be considered for each Socio-Economic VESEC.

11.2 COMMUNITY INFRASTRUCTURE AND SERVICES

11.2.1 Assessment Indicators and Assessment Parameters

Project effects on community infrastructure and services were assessed by taking into consideration changes in the demand for housing and temporary accommodation, physical infrastructure, social services, and in the use of transportation infrastructure from existing conditions. The assessment indicators and parameters selected for the assessment of potential Project effects on the Community Infrastructure and Services VESEC are provided in **Table 3-2** in **Section 3 Methods**.

11.2.2 Project Interactions and Potential Effects

The assessment approach for identifying Project interactions and potential effects was a systematic review of each of the listed Project components or activities within the context of existing conditions of the LSA for each of the indicators and assessment parameters of the Community Infrastructure and Services VESEC. As indicated in **Table 3-4** in **Section 3 Methods**, the Project is anticipated to interact with community infrastructure and services. Most of the interactions with Project components and activities expected to result in either no effects or small effect that would result in no measurable change from existing conditions. These interactions and effects are described in **Section 11.2.2.1 Rationale for No or Negligible Interaction** to provide a rationale for these findings. Interactions that are anticipated to result in a more substantial effects are described in **Section 11.2.2.2 Interactions**.

11.2.2.1 Rationale for No or Negligible Interaction

Potential interactions that were evaluated as having no or negligible interactions with the Project are described below. These are not further considered in the assessment.

11.2.2.1.1 Demand for Housing or Temporary Accommodation

Project workforce requirements will vary over the life of the Project and will ultimately be limited by the existing Chance Camp capacity of approximately 75 people on-site. Chance plans to hire from local communities such as Old Crow, Fort McPherson, and Dawson City were possible. With the relatively small workforce requirements, and use of the main camp (and remote or mobile camp facilities) for accommodation, it is not expected that workers and their families will relocate to local communities within the LSA and create a measurable demand on housing beyond current levels. As a result, no effect is expected for the demand on housing and is not considered further in the assessment.

There is a potential for minor Project effects on the demand for temporary accommodation related to overflow from the existing 75-person Chance Camp. The Eagle Plains Hotel, located 40 km away, can accommodate up to 64 people and has an associated Recreational Vehicle (RV) campground. Effects related to temporary accommodation are dependent on the size of the workforce that requires temporary housing but are expected to be minor and temporary, and related most typically to periods of winter exploration activities.

The Eagle Plains Hotel is a destination in the summer for motorists travelling along the Dempster Highway and effects may be more pronounced if they occur during this period. Beyond the early period of construction near the main Chance Camp site, the summer workforce related to the seismic exploration is expected to be accommodated by the Chance Camp. Chance will coordinate requirements for overflow accommodation with the Eagle Plains Hotel staff to minimize effects on other seasonal users and avoid restricting accommodation for other projects or activities during potential overflow periods. As a result, a negligible effect is expected for the demand on housing related to temporary accommodation and the potential effect is not considered further in the assessment.

11.2.2.1.2 Demand for Physical Infrastructure

The main Chance Camp, located at km 325 of the Dempster Highway, is accessible year-round and is used for storing and transporting equipment and supplies needed for well maintenance operations and exploration activities. It has accommodations for up to 75 people in trailers, as well as kitchen facilities, wastewater treatment, sanitary facilities (washing, showers, toilets) and potable water. During the seismic and drilling programs, workers are expected to use amenities at the main camp.

During Project exploration activities, water at the Chance Camp used for sanitary purposes will be extracted from local surface water sources and may be stored in a water reservoir at the camp. Source and volumes of water will be in accordance with issued water permits. Fuel stored at the main camp (diesel and propane) will be used for heating and electricity generation. All garbage and recyclable materials will be taken off site and disposed of at facilities licensed to accept such material. Hazardous waste material associated with operation of the Chance Camp (e.g., used motor and hydraulic oils, chemical cleaning fluids, batteries) will be sorted and either recycled or disposed of following the waste management procedures included in the Project Environmental Management Plan. It is expected that solid and hazardous waste disposal will be within the existing capacity of landfills and recycling facilities already utilized by the Chance Camp.

Well sites will include mobile camps comprised of trailers as accommodation and offices for the rig crew and personnel, a garbage incinerator, and water storage tank and treatment containers to provide potable water. Well sites will utilize portable generators for power. All wastewater and sewage will be collected and transported off-site for disposal at an approved facility. Hazardous waste material associated with operation of the mobile camps will be managed in the same way as at the main Chance Camp.

Construction activities will occur in the early period of the Project and are related to the Central Processing Facility (CPF) adjacent to the existing Chance Camp, as well as the airstrip, and other surface facilities. It is expected that construction workers will use amenities and physical infrastructure at the Chance Camp during the early period of the Project (i.e., electricity sources, potable water, waste disposal). Additional water used for construction (e.g., dust suppression and material production) is expected be in accordance with issued water permits. Construction-related wastewater will be treated at the wastewater treatment facilities on-site, and solid waste material will be sorted and either recycled or disposed at sites authorized and with capacity to accept such material.

As municipal infrastructure requirements for the Project are expected to be minimal (i.e., solid waste management) and to be within permitted limits, the Project is not expected to result in a change in the demand for physical infrastructure from existing conditions. As a result, the potential effects on physical infrastructure are not considered further in the assessment.

11.2.2.1.3 Demand for Community Healthcare Services and Cultural and Recreation Services

The communities within the LSA provide a variety of community services related to primary and long-term healthcare (e.g., hospitals, community clinics, and nursing and residential care facilities), as well as cultural and recreation services (e.g., museums, galleries and historical sites, libraries, cultural centres and community recreation facilities). Some of these services are available regionally (i.e., in Whitehorse), while others are provided within individual local communities. A new health centre is planned to replace the existing community health centre in Old Crow and is anticipated for completion in 2024. The new health centre will provide regional social services, home care services, mental wellness and substance use services, as well as community nursing health services. There are counsellors who rotate through Old Crow on a monthly basis providing mental wellness, substance use, and youth counselling services. Dawson City has a range of health care facilities, including a hospital, a nursing and residential care facility that offer women's health, and other facilities offering chronic disease follow-up services, geriatric services, home visits, health education, and communicable disease programs and services. Based on available information, many of these facilities have the capacity to service existing community needs, although some services are limited in particular communities (e.g., childcare services, alcohol and drug addiction support services) and experience staffing challenges.

Project workforce requirements will vary over the life of the Project but are expected to be equivalent to up to 70 jobs. Chance plans to hire from local communities where possible. With the relatively small workforce requirements, and use of the main Chance Camp (and remote or mobile camp facilities) for accommodation, it is not expected that workers and their families will relocate to communities within the LSA and create a measurable demand on existing community long-term health services, or cultural and recreational facilities and services beyond existing conditions. As a result, the potential effects on community healthcare services and cultural and recreation services are not considered further in the

assessment. Effects related to health and wellbeing of citizens within the communities is assessed within **Section 11.4 Community Health and Wellbeing**.

11.2.2.1.4 Demand for Educational Services

Communities within the LSA are home to a variety of educational facilities, including Yukon University's regional campuses with available programs for certificates, diplomas, degrees and vocational training. The Old Crow campus of Yukon University offers in-person training such as culinary, driving (Class 5 and Class 7) and first aid courses. It has been expressed that educational opportunities in local communities are limited, particularly for local residents seeking training related to jobs in the resource industry. Further training opportunities at educational facilities within the RSA (and beyond), such as those in Whitehorse or Alberta, may be facilitated through remote learning, or require travel to access educational programs and services. Although the range of educational services for local residents supports training opportunities to meet some of the requirements for the regional labour market, there are barriers to access.

Project workforce requirements will vary over the life of the Project but are expected to be equivalent to up to 70 jobs. Chance plans to hire from local communities where possible. Based on current labour force statistics within the LSA, it is anticipated that a relatively small local workforce is available with the skills and experience related to Project workforce needs. Engagement activities for the Project have identified community concerns over the capacity of local communities to meet the demand for employment opportunities without further training and funding. Skills and training related to jobs for the drilling and seismic programs (e.g., truck driver/operators, flow test crew, surveyors, wildlife monitor), and camp operations (e.g., cooks, attendants, cleaning staff) are likely to be required for prospective Project workers within the LSA as there are a number of credentials needed to meet occupational health and safety requirements (e.g., Workplace Hazardous Materials Information System [WHMIS], Emergency First Aid, H2S Aware, Foodsafe). Additional specific training will be required to meet industry standards related to jobs for the drilling and seismic programs. The number of potential workers in the LSA who may require training to access job opportunities is difficult to predict, however, for the purposes of this assessment, it is anticipated that this may be a modest subset of the total predicted workforce hired locally.

Training and employment opportunities will be tied to the success of the exploration program. Chance will coordinate with local and regional education and training organizations or institutions to communicate and encourage the provision of programs or courses necessary to meet Project workforce requirements. The availability and enrolment in training opportunities may result in an increased demand for education services. Educational services within the LSA and RSA are anticipated to have the capacity to accommodate a modest increased demand for vocational training considering their historic responsiveness to coordinating trades and vocational programming; the availability of particular programs is uncertain at this time. It is possible that some apprenticeship programs and accreditations which would involve training may not be available readily from education and training organizations in the LSA or RSA.

Based on the modest number of workers that are anticipated to require training within the LSA for the proposed Project and the potential access to a range of available education programs and services in the LSA or RSA (or beyond), it is expected that the incremental increased demand for training is not likely to adversely affect education services in the LSA. There is the potential for a positive effect on education services within communities related to the Project stimulating the expansion or addition of programs available for local residents. This would enable more local residents to meet the employment requirements

of the Project and the broader regional labour market. As a result, effects on educational services are not considered further in the assessment.

11.2.2.1.5 Demand for Community Social Services

Communities within the LSA provide a variety of social services such as childcare, eldercare and assisted living, addiction services, services for people with disabilities, child welfare and adult protection services. Some of these services are available within individual local communities in the LSA and others are available regionally (i.e., within Whitehorse). Based on available information, many of these community service providers have the capacity to service existing community needs, although some services (e.g., childcare services, alcohol and drug addiction support services) are limited in particular communities. A new health centre and housing complex is planned to be completed in Old Crow in 2024. This new facility will provide regional social services, home care services, mental wellness and substance use services.

The Project will require rotational shiftwork that will typically be structured around a 20-day-on and 10-day-off crew rotation cycle. This will take local residents who are employed by Chance out of their communities and away from their families for extended periods during a crew rotation cycle. Community members who are employed for the Project may require access to social services, such as childcare or eldercare and assisted living, to support community or family obligations while participating in the Project's workforce. The number of workers in the LSA who may require support from social services is difficult to predict, however, for the purpose of this assessment it is assumed that the proportion of workers requiring these services is a modest subset of the total predicted workforce. The need for and selection of social service options is a highly personal choice and will likely depend on factors such as availability, suitability and cost. Where social services are limited within a community, there is the potential for additional Project-related demand on social services to result in a more pronounced but generally minor effect.

The assessment of **Section 11.4 Community Health and Wellbeing** did not identify the potential for the Project to result in any noticeable change in community mental health and wellness (e.g., substances use) or safety (e.g., family violence) that would result in an increased demand on the community social services for support. It is not expected that workers and their families within local communities will contribute measurably to an increased demand for existing community social services. The demand for certain social services varies depending on the challenges providing those services in individual communities. For example, Dawson has experienced a shortage in availability of childcare services. Old Crow experienced an addictions crisis in 2023 that resulted in increased access to alcohol and drug addiction support services.

The potential incremental Project-related effects on community social services is negligible and is not considered further in the assessment.

11.2.2.1.6 Demand for Emergency Response Services

Communities within the LSA are serviced by a number of emergency response providers. Fire protection services are provided by local departments of staff and volunteers. Ambulatory services are coordinated by the Yukon Emergency Medical Service through local ambulance stations and the Air Ambulance Program. The Royal Canadian Mounted Police (RCMP) provides police services through local detachments in LSA communities.

There is a potential for the Project to increase demand for emergency ambulance services in the event of work-related accidents and injuries, police services in the event of Project-related security or safety issues, or fire response services in the event of fire at accessible Project facilities. Use of the main Chance Camp and the Project's exploration activities will include detailed safety measures in accordance with accepted industry practices and standards to prevent and manage emergencies, including health and safety management, training and emergency response planning, onsite fire detection, and control and response systems. The Chance Camp will include first aid facilities and trained personnel to provide primary care in the event of an accident, and to address minor injuries. The drill and seismic exploration activities will include support by trained first aid staff and remote medical supplies or first aid facilities. Trauma patients requiring further medical attention will be transported to nearby facilities such as the Dawson City Community Hospital or facilities in Whitehorse. It is anticipated that the Chance Camp will include private security personnel and monitoring systems to provide site safety and security. The Project's emergency response management will be coordinated with, but independent of, existing emergency response services within the LSA.

Construction activities will occur in the early period of the Project related to the CPF, as well as the airstrip, and other surface facilities. Construction activities could potentially generate a demand for emergency response services in the event of construction-related accident or incident. Contractors and other suppliers are expected to adhere to Project health and safety management and provide emergency response management during construction. Communications plans will be developed as part of the Environmental Management Plan (EMP) to inform emergency service providers of construction activity and expected delays well in advance, to prevent delay in response to non-Project emergencies within the LSA.

Based on health and safety procedures, emergency response facilities and management plans that are expected to be in-place at the main Chance Camp or for remote exploration activities, the Project is not anticipated to contribute to a change in demand for emergency response services in the LSA beyond existing conditions. As a result, the potential effect on emergency response services is negligible and is not considered further in the assessment.

11.2.2.1.7 Transportation Infrastructure Road Conditions and Safety

The surface of the North Klondike Highway is paved. The surface of the Dempster Highway is predominately gravel with some paved sections near Dawson City and Inuvik. General wear and tear on these highways results from harsh winter conditions, use by heavy trucks and other vehicles, as well as thawing permafrost. Road maintenance crews are continually grading and repairing the Dempster Highway and provide ongoing maintenance to the North Klondike Highway. The governments of Canada and Yukon have dedicated funding for rebuilding and rehabilitating portions of the North Klondike Highway focused at increasing resistance to climate change (e.g., thawing permafrost) and to upgrade the road for use by larger vehicles and higher levels of traffic. In winter, both highways are snow-packed and winter maintenance of road surfaces includes snow removal, application of anti-icing and sanding materials, and removal of drifts, slides and avalanches.

Project-related traffic, particularly heavy trucks, have the potential to contribute to increased wear and tear of public roadways including the Dempster Highway and the North Klondike Highway. It is expected that the movement of heavy and/or oversized loads during construction in the early period of the Project would involve temporary increases in the volume of large vehicles, particularly during the summer. Traffic

management measures for public road use will be developed and incorporated into the Project EMP. These would include compliance with road use and safety requirements, speed limitations to minimize damage to road surfaces, and coordination with the Yukon Department of Highways and Public Works. Project-related traffic along public roads during the winter will occur when potholes or surface breakup is less prevalent, and snowpack and winter conditions provide some protection for the road surface and structure. Considering the current pattern of use by larger vehicles (e.g., heavy trucks, RVs) and typical road conditions along the Dempster Highway and the North Klondike Highway, the estimated volume of Project-related vehicle traffic (a potential increase of approximately 6 to 8 vehicles per day) would not contribute to wear and tear on the roads beyond what is expected to be addressed by ongoing maintenance programs. As a result, the potential effect on transportation infrastructure road conditions is determined to be negligible and is not considered further in the assessment.

The Yukon has a relatively high overall risk of motor vehicle collision injuries and fatalities (see **Section 11.4 Community Health and Wellbeing**). The Yukon also exhibits variability in access to trauma care related to traffic incidents, and enforcement measures in remote areas that can contribute to higher rates of causality. Project-related traffic management measures, such as Journey Management planning, security monitoring, and radio controls will be incorporated into the Project EMP and implemented to effectively manage safe use of public roads by Project traffic vehicles. Considering the estimated volume of Project-related vehicle traffic volume (a potential increase of approximately 6 to 8 vehicles per day) and traffic management procedures to be implemented, the rate of motor vehicle collision injuries and fatalities is not expected to experience a measurable change from existing conditions. The potential effect on the safety of transportation infrastructure is negligible and is not considered further in the assessment.

11.2.2.2 Interactions

Project components and activities interactions with land and resource use were evaluated following the approach in **Section 3.1.4.1 Project Interactions and Potential Effects**. Only one potential effect on community infrastructure and services is expected. A potential effect on the pattern of transportation infrastructure from increased traffic is expected to result from Project components and activities as shown in **Table 11-3** below. The pathway for the potential adverse effect is described in the following section.

Table 11-3. Expected Interactions between Community Infrastructure and Services and the Eagle Plains Exploration Project and Resulting Potential Effects

Project Component / Activity	Increased Traffic
Engagement	0
Seismic Exploration	1
Drilling Exploration	1
Extended Flow Testing (EFT)	1
Well Maintenance (Workovers)	1
Winter Access Roads	0
Mix Bury Cover (MBC)	1
Central Processing Facility (CPF)	0

Project Component / Activity	Increased Traffic
Airstrip	0
Water Withdrawal	0
Transportation	2
Camp	1
Reclamation and Closure	0

Notes:
0 = no interaction. A rationale for no effects is addressed in **Section 11.2.2.1 Rationale for No or Negligible Effects**.
1 = minor interaction with community infrastructure and services is possible, but small immeasurable effect. A rationale for negligible effects is addressed in **Section 11.2.2.1 Rationale for No or Negligible Effects**. This rating does not lead into residual effects characterization.
2 = substantial interaction with community infrastructure and services, designates a more detailed assessment of potential effects. Carry forward into residual effects characterization.

11.2.2.3 Increased Traffic

The Project is expected to result in an effect on the use of transportation infrastructure from increased traffic. Concerns related to increased traffic on the Dempster Highway from proposed Project-related traffic have been expressed through engagement with local communities and First Nations. Project traffic from construction and exploration activities may have an effect on public transportation infrastructure due to the increased traffic associated with the movement of material, equipment, and workers to and from the Project footprint. This potential effect is contingent on the volume of proposed Project-related traffic, the schedule of Project-related traffic, and the levels of traffic in the LSA.

Project-related vehicles will use portions of the Alaska Highway and Klondike Highways to access the Dempster Highway and the Project footprint or related access roads. The existing pattern of traffic conditions for the Alaska Highway and Klondike Highway are related to local and regional traffic between communities such as Whitehorse, Haines Junction, Carcross, Carmacks, and Dawson City, as well as seasonal tourism and recreation within the Yukon. The Alaska Highway and most of the Klondike Highway will not likely experience a noticeable effect on existing traffic patterns considering the relatively high volume of traffic on these routes. As a result, this assessment of potential effects on transportation infrastructure focuses on the portion of the North Klondike Highway near the entrance to the Dempster Highway (between Dawson City and Highway #11 junction to Mayo), and the Dempster Highway extending to Fort McPherson in the NWT, where the effects of Project-related traffic are most likely to occur.

Traffic on the Project-controlled winter access roads (e.g., Chance Road, Blackie Road) will be limited to authorized personnel and controlled to the extent possible. These access roads are private roads and are not considered in the assessment of transportation infrastructure which focuses on public roadways. Effects on Project-related access roads will be assessed in the Land and Resource Use VESEC (**Section 11.3**). Use of public transportation infrastructure for the movement of equipment, materials for use along the access roads into and out of the Project footprint (e.g., road grader, service rigs) is considered in the analysis below.

It is expected that the initial mobilization and movement of exploration and drilling equipment and materials to and from the Project footprint will result in increased traffic on public roadways connected to the Project

footprint, such as sections of the Dempster Highway. The seismic exploration program will include the mobilization of larger vehicles and equipment (e.g., mulchers, drill vehicles, water trucks, and picker trucks), as well as smaller vehicles and equipment (e.g., light-duty trucks, all-terrain vehicles [ATVs]/snowmobiles, and storage trailers) to the main Chance Camp or staging areas related to winter access roads. The drilling program will include the mobilization of drill rigs and other equipment or materials for establishing well sites (e.g., matting material, boilers, incinerators, ancillary trailers, storage units and tanks) to the main Chance Camp or staging areas. The movement of this equipment and materials along public roadways is expected to occur infrequently and over relatively short periods (i.e., days). As a result, the movement of exploration and drilling equipment and materials represents a temporary effect on transportation infrastructure.

Similarly, the occasional movement of Project vehicles and material related to ongoing operations and maintenance (e.g., EFT, well maintenance activities, and MBC) has the potential to result in increased traffic on public roadways. While crude oil produced during the EFT will be preferentially stored temporarily for future shipment to market, this may require some truck transport to a suitable crude oil marketing point off-site. The amount of crude oil that may need to be transported offsite is currently uncertain, but it is anticipated this would result in little to no additional traffic to and from the Project site during EFT for the purposes of this assessment.

Completed or suspended wells may require ongoing maintenance during the Project's 10-year lifespan. Maintenance activities may be required regularly on an annual basis and involve the mobilization of service rigs and crews to and from the Project footprint along public roadways. Regular well maintenance activities will primarily use access roads involving minimal use of public roadways and will be consistent with existing levels of industrial-related vehicle traffic within the LSA for projects such as roadway maintenance and resource use. Operation of the MBC will involve the regular transportation of drill cuttings from the well sites to the MBC along public roadways. The preferred MBC location is along the Dempster Highway near km 336. It is expected that regular transport of drilling waste will be focused on a small portion of the Dempster Highway and will be consistent with existing levels of industrial-related vehicle traffic within the LSA for projects such as roadway maintenance and resource use. As a result, the movement of vehicles and material related to EFT, well maintenance activities, and MBC operation represents a temporary effect on transportation infrastructure.

Continued use of the main Chance Camp for rotational shiftwork will minimize traffic related to a commuting workforce. During the 10-year life of the Project, planned Project-related off-site traffic between the site and supply points will involve approximately 40 to 50 vehicles per week on public roads during the winter; a potential increase of approximately 6 to 8 vehicles per day. This will involve water and fuel trucks (transiting to the Project footprint approximately three times per week), and lightweight service vehicles travelling along portions of the North Klondike Highway and the Dempster Highway to the Chance Camp as required. Project activity in the summer will be primarily related to seismic recording and EFT, and for the purposes of this assessment will assume the same volume of Project-related traffic as winter.

Traffic volumes along the North Klondike Highway and the Dempster Highway within the LSA are generally low relative to traffic volumes in the region. Traffic volumes along the North Klondike Highway are characterized by annual average daily traffic of between 207 and 296 vehicles. Traffic volumes along the Dempster Highway are characterized by annual average daily traffic of between 63 and 108 vehicles. In the summer, there is an approximately 63.2% average increase of average daily traffic related to seasonal tourism and recreation traffic and road maintenance or industrial activity. The change in traffic volume along

the North Klondike Highway related to the planned Project-related off-site traffic would represent an average increase of approximately 2.5% to 3.2% of the annual average daily traffic and 1.6% to 2.1% of the average summer daily traffic22. The change in traffic volume along the Dempster Highway related to the planned Project-related off-site traffic would represent an average increase of approximately 7.2% to 9.4% of the annual average daily traffic and 4.3% to 5.7% of the average summer daily traffic. This level of increased traffic (< 10%), while potentially noticeable, is not expected to affect the overall use of the North Klondike Highway and Dempster Highway beyond existing conditions. The change in traffic would represent a minor increase in the traffic volume that would likely be most evident in the summer months when Project vehicles would overlap with the highest volume of tourism and recreation traffic, road maintenance or industrial activity in the region[23]. It is expected that increased traffic would be experienced as an inconvenience (e.g., reduced speeds) or as a nuisance effect (e.g., dust) by other motorists and highway users.

Construction activities will occur related to the CPF, the airstrip, and other surface facilities near the Chance Camp. Construction activities will potentially generate traffic related to transport of construction material, equipment, and workforce as well as site preparation and the building of facilities. Construction in the early period of the Project is anticipated to last up to two years and would primarily occur between late spring and early fall. While it is expected that construction workers will use the main Chance Camp to minimize traffic related to a commuting workforce, there is the potential for some contractors and/or suppliers to commute to the Project footprint for occasional portions of construction. For the purposes of this assessment, traffic related to transport of construction-related material, equipment, and workforce is represented conservatively as an increase of 25% of Project-related off-site traffic described above. During the early period of the Project, the increase in planned Project-related off-site traffic and estimated construction traffic volume along the North Klondike Highway would represent an average increase of approximately 8.2% of the annual average daily traffic and 2.5% of the average summer daily traffic. During the early period of the Project, the incremental increase in planned Project-related off-site traffic and estimated construction traffic volume along the Dempster Highway would represent an average increase of approximately 12.0% of the annual average daily traffic and 7.4% of the average summer daily traffic. The additional temporary increase in construction-related traffic volume, while potentially noticeable, would not affect the overall use of the North Klondike Highway and Dempster Highway beyond existing conditions. This would represent a minor increase in the traffic volume that would likely be most evident in the summer months. There would be the potential for construction-related transport of materials to affect public road use through intermittent delays during the movement of large or hazardous loads along the North Klondike Highway and Dempster Highway.

Chance is proposing to construct an airstrip along the existing Chance winter trail approximately 4 km off the Dempster Highway. This airstrip will be used seasonally during the winter for transportation of staff to and from the Chance Camp. The proposed airstrip may be upgraded if additional air traffic support is required. Chance will continue to use a portion of the Dempster Highway near to the Chance Camp (i.e.,

[22] Project-related traffic represents a smaller percentage increase in the summer due to the annual average daily summer traffic in the region being higher during this part of the year than the annual average daily traffic.

23 Although this period represents a smaller incremental increase in traffic volume compared to winter, it is the period mostly likely to result in interactions with other highway users and the greater potential to produce an acute effect.

the Wiley Aerodrome) until the airstrip becomes serviceable and as an airstrip during the summer. Project-related air traffic is estimated to be two flights in/out per week. The establishment of a new airstrip along the Chance winter trail will eliminate interactions with the Dempster Highway during the winter.

The existing Wiley Aerodrome is currently used for seasonal traffic related to tourism and mining activities, and emergency services. Management of this site is informed by Canadian Aviation Regulations and road signage identifies the aerodrome to motorists. Ongoing seasonal use of this aerodrome has the potential to result in brief delays on a weekly basis during the summer months but will be consistent with current controlled use of this transportation infrastructure.

11.2.3 Mitigation Measures

The Project design includes management measures to avoid or reduce anticipated effects that have been identified through ongoing engagement, applicable standards, guidelines, and Best Management Practices. These include the components listed in **Table 11-4** relevant to addressing Project-related effects on traffic.

Table 11-4. Mitigation Measures Relevant to Community Infrastructure and Services and the Eagle Plains Exploration Project

Mitigation and Management Measure	Potential Effect Addressed by Mitigation
Continued use of the main Chance Camp and remote camps to accommodate employees	Increased traffic
Implementation of traffic management measures for safe road use incorporated into the Project EMP that include compliance with road use and safety requirements, access controls and signage, and coordination with the Yukon Department of Highways and Public Works as warranted.	Increased traffic

No further mitigation measures were identified to address potential Project effects on the use of transportation infrastructure from increased traffic.

11.2.4 Effects Characterization

11.2.4.1 Approach

The assessment approach used to characterize the predicted adverse residual effect to community infrastructure and services follows the methodology outlined in **Section 11.1.4 Methods: Effects Assessment.** The residual effect characterization is based on criteria specific to socio-economic VESECs, as presented in **Section 11.1.4.3 Methods: Characterization of Residual Effects**.

11.2.4.2 Residual Effect

After mitigation is applied, a residual effect on the Community Infrastructure and Services VESEC is expected, in the form of a change in the use transportation infrastructure from increased traffic. This residual effect is characterized in **Table 11-5** below.

Table 11-5. Characterization of Residual Effects on the Use of Transportation Infrastructure from Increased Traffic

Criterion		Rating	Rationale
Magnitude		Low	Project-related vehicles for the seasonal exploration programs and early construction have the potential to result in a minor increase in traffic that would be potentially distinguished within the existing volume of traffic along the Dempster Highway and portions of the North Klondike Highway
Likelihood		Probable	A Project-related increase in traffic will likely occur as a result of planned Project-related off-site traffic between the site and supply points.
Geographic Extent		Local	Project-related increase in traffic is expected be localized to portions of the Dempster Highway and portions of the North Klondike Highway
Duration, Frequency and Timing	Duration	Medium-term	Project-related increase in traffic is expected occur throughout the life of the Project (i.e., 10 years)
	Frequency	Periodic	Project-related increased traffic is related to the regular (three times per week) and/or scheduled (during construction) movements of material, equipment, and workers to and from the Project
	Timing	Seasonal (Summer)	While Project-related change in the pattern of transportation infrastructure from increased traffic will occur consistently throughout the year; effects are likely to be most evident in the summer when they overlap with tourism and recreation, road maintenance or industrial activity in the region
Reversibility		Reversible	The Project-related increased traffic will decrease or stop with closure and reclamation of the Project.

11.2.4.2.1 Context and Confidence

The Project's environmental and/or socio-economic context and potential limitations of data and uncertainty associated with the assessment are considered in determining adverse residual effects of increased traffic. The ratings and rationale for the context and confidence of predicted residual effects are described in **Table 11-6**.

Table 11-6. Context and Confidence of Residual Effects on Community Infrastructure and Services

Criterion	Rating	Rationale
Context	Moderate	The role of transportation infrastructure within the LSA (i.e., the Dempster Highway and portions of the North Klondike Highway) for community connectivity, recreation, tourism, and other uses are reasonably documented and understood. Concerns have been expressed about a Project-related increase in traffic on the Dempster Highway through engagement with local communities and First Nations.

Criterion	Rating	Rationale
Confidence	Moderate	Traffic count information used to characterize the existing traffic volumes of the Dempster Highway and portions of the North Klondike Highway are limited to data from a 2011 survey. This was addressed with the use of other more current data for a portion of the Dempster Highway in NWT. There is uncertainty of Project-related traffic levels related to some activities such as construction of Project facilities, mobilization of exploration, and ETF. Traffic management strategies are based on road use and safety requirements that have proven to be effective.

11.2.5 Significance

The determination of significance of the predicted residual effects of increased traffic is based on definitions presented in **Section 11.1.4.3 Methods: Characterization of Residual Effects**. Magnitude, geographic extent, and duration are the primary factors affecting the significance determination.

The predicted Project-related increase in traffic has the potential to result in a minor change to the use of transportation infrastructure that, while potentially noticeable, would not affect the overall use of the North Klondike Highway and Dempster Highway beyond existing conditions. Residual effects are predicted to be localized and occur over the 10-year life of the Project. With the implementation of traffic management measures for safe road use, the residual effects of the Project on the use of transportation infrastructure are anticipated to be **not significant**.

11.2.6 Follow-up Monitoring

To address the uncertainty of potential interactions of the Project, follow-up monitoring is required to identify unanticipated social effects and to respond adaptively through coordination with First Nations, residents of local communities, and the Yukon Environmental and Socio-economic Assessment Board (YESAB) Executive Committee or relevant regulators (if required). Chance will organize and implement coordination of follow-up monitoring to support identification and response to potential community and economic effects of the Project. This coordination will involve the review of results from Chance's proposed follow-up monitoring programs as well as feedback from First Nations and local communities to provide direction on the adaptive implementation of Project design, mitigation and benefit enhancement measures related to potential socio-economic effects.

11.2.7 Cumulative Effects Assessment

11.2.7.1 Approach

The assessment of cumulative effects on the Community Infrastructure and Services VESEC follows the methods outlined in **Section 3.1.6 Cumulative Effects** and **Section 11.1.4.6 Cumulative Effects**. The community infrastructure and services CEA considers potential residual effects of the Project on the use of transportation infrastructure from Project-related changes in traffic volumes that may interact spatially and temporally with past, present and reasonably foreseeable projects and activities listed in **Table 3.8** in **Section 3 Methods**.

Due to the limitations in available traffic count data for the Dempster Highway (see **Section 11.1.1.3.1 Data Limitations**), it is expected that the characterization of existing conditions does not account for traffic volumes associated with most currently active and ongoing gravel quarries, the Ogilvie Grader Station Solar, Eagle Plains Solid Waste Disposal, or the Yukon Fiber Optic Network projects. There is also uncertainty about the schedule of vehicle movement for these projects beyond the general seasonal nature of their operations. A conservative approach was taken that considers the context and likelihood of cumulative effects with the residual effects of the Project.

11.2.7.2 Cumulative Effects

Since residual effects of Project-related changes in traffic volumes will be most evident along the Dempster Highway, the CEA focused on projects and activities that may impact Dempster Highway traffic volumes. Projects and activities that may contribute to increased traffic on the Dempster Highway are presented in **Table 11-7** below. These include regular maintenance of the Dempster Highway, the transport of aggregate to and from gravel pit sites, the movement of material, equipment, and workers to project sites and temporary camps, the removal and disposal of hazardous waste, and ongoing post-closure monitoring.

Table 11-7. Past, Present, and Reasonably Foreseeable Projects and Activities with Potential to Act Cumulatively with Project Effects on Community Infrastructure and Services

Project Name or Activity	Spatial / Temporal Overlap	Project or Activity Contributions
Dempster Highway (ongoing)	• Within RSA (along the Dempster Highway) • Overlaps with 10-year Life of Project	• Increased traffic from regular maintenance (e.g., grading and repairing) of the Dempster Highway
Dempster Highway Granular Pit Development: km 188, 208, and 232 (proposed)	• Within RSA (within 93 to 137 km from Project) • Overlaps with 10-year life of Project (project activity will occur every 2–3 years until 2046)	• Increased traffic from transportation of aggregate and equipment from pit sites, as well as materials to temporary camp.
Sheep Creek Gravel Pit: km 433 Dempster Highway (ongoing)	• Within RSA (within 108 km from Project) • May overlap early period of Project (project activity will occur every 2–3 years until 2031)	• Increased traffic from transportation of aggregate and equipment from pit site.
Ogilvie Grader Station Solar, km 195 Dempster Highway (ongoing)	• Within RSA (within 130 km from Project) • May overlap early period of Project (construction to start from 2023–2028 and last 4 month. Lifespan of project is 25 years)	• Increased traffic from movements of material, equipment, and workers during construction
Granular Pit Exploration + Development – km 158 (ongoing)	• Within RSA (167 km from Project) • Overlaps with 10-year life of Project (activity will occur every 3–5 years)	• Increased traffic from transportation of aggregate and equipment from pit, as well as materials to temporary camp.
Eagle Plains Solid Waste Disposal (ongoing)	• Within RSA (approximately 15 km from Project) • Overlaps with 10-year life of Project (to occur over the 25 years, starting in 2024)	• Increased traffic from removal and disposal of hazardous waste stockpile, site stabilization, and post-closure monitoring

Project Name or Activity	Spatial / Temporal Overlap	Project or Activity Contributions
Yukon Fiber Optic Network (ongoing)	• Within RSA (along the Dempster Highway) • May overlap early period of Project (to occur 2020 and 2025)	• Increased traffic and roadside work from installation of fibre optic line along right-of-way
ROHL Camp (ongoing)	• Within RSA (approximately 65 km from Project footprint) • May overlap early period of Project (to occur 2020 and 2025)	• Increased traffic from movements of material, equipment, and workers to temporary work camps
Mineral Exploration	• Within RSA (potentially accessed along the Dempster Highway) • May overlaps with 10-year life of Project	• Increased traffic from movements of material, equipment, and workers to exploration sites
Gravel quarries- Unnamed	• Within RSA (potentially accessed along the Dempster Highway) • May overlaps with 10-year life of Project	• Increased traffic from movements of material, equipment, and workers to quarry sites
Oil and Gas	• Within RSA (potentially accessed along the Dempster Highway) • May overlaps with 10-year life of Project	• Increased traffic from movements of material, equipment, and workers to oil and gas exploration sites

Not all ongoing and proposed projects and activities will overlap the full 10-year life of the Project. The Eagle Plains Solid Waste Disposal project, Yukon Fiber Optic Network, and ROHL Camp are likely to overlap only the first few years of the Project if scheduled operations occur as planned. Nearly all the listed gravel pit projects will occur every 2–5 years resulting in periodic contributions to increased traffic along the Dempster Highway.

While each ongoing and reasonably foreseeable project is expected to contribute to minor changes in Dempster Highway traffic, there is the potential for occasional periods of delay or disruption should the traffic volume combine from multiple projects in a given period.

Placer and quartz claims, and land use permits for gravel extraction occur on lands within the RSA that may be accessed from the Dempster Highway. Oil and gas exploration in the region is primarily related to the Chance exploration claims. As a result, there is the potential for mineral exploration and the development of future gravel quarries that may use the Dempster Highway to access lands and result in increased traffic activities from movements of material, equipment, and workers. Cumulative effects from these activities are expected to occur seasonally with unknown operation dates.

A characterization of cumulative effects for a change in the use of transportation infrastructure from increased traffic is provided in **Table 11-8** below.

Table 11-8. Characterization of Cumulative Effects on the Use of Transportation Infrastructure from Increased Traffic

Criterion		Rating	Rationale
Magnitude		Low	Ongoing projects and other reasonably foreseeable projects that may use the Dempster Highway to access lands have the potential to act cumulative with the regular and/or scheduled movements of material, equipment, and workers to and from the Project footprint. It is expected that the incremental increase in overall traffic will not be noticeable within existing conditions but may result in reduced speeds and/or delays.
Likelihood		Certain	The likelihood of cumulative effects from increased traffic is certain as most of the other projects and activities are existing and ongoing with planned schedules of operation.
Geographic Extent		Local	The cumulative effect of increased traffic is expected to be localized to the Dempster Highway.
Duration, Frequency and Timing	Duration	Short-term to Medium-term	The cumulative effect of increased traffic is expected to occur throughout the life of the Project (i.e., 10 years) with some of the other projects and activities scheduled to overlap for only the first few years of the Project.
	Frequency	Periodic	The cumulative effect of increased traffic from other projects and activities are expected to generally occur seasonally with most occurring every 3–5 years.
	Timing	Seasonal	The cumulative effect of increased traffic from other projects and activities are expected to occur seasonally, and are likely to be most evident in the summer when they overlap with tourism and recreation, road maintenance or industrial activity in the region
Reversibility		Reversible	The cumulative effect of increased traffic will decrease or stop with closure and reclamation of the Project and/or other projects and activities.

Potential climate change effects could cumulatively interact with residual Project effects and anticipated ongoing and proposed projects and activities effects resulting in changes to transportation infrastructure over the 10-year life of the Project. Climate change effects such as extreme weather events could result in seasonal disruption to use of transportation infrastructure from poor driving conditions for motorists along the Dempster Highway and portions of the North Klondike Highway such as winter storms or increased dust or airborne particulate matter from wildfire events. Events such as flooding, erosion, and permafrost thaw may also reshape the condition of roads for use by communities, commercial operators, recreational users and tourists. These climate change interactions have the potential to combine with the cumulative effect of increased traffic to result in further disruptions or delays to the use of the Dempster Highway.

11.2.7.3 Context and Confidence

The Project's environmental and/or socio-economic context and potential limitations of data and uncertainty associated with the assessment were considered for the assessment of cumulative effects. The ratings and rationale for the context and confidence in accurately quantifying and predicting cumulative effects are described in **Table 11-9** below.

Table 11-9. Characterization of Context and Confidence in the Assessment of Cumulative Effects on Community Infrastructure and Services

Criterion	Rating	Rationale
Context	Moderate	• The role of transportation infrastructure within the LSA (i.e., the Dempster Highway and portions of the North Klondike Highway) for community connectivity, recreation, tourism, and other uses are well documented and understood. • Concerns have been expressed related to a Project-related increase traffic on the Dempster Highway through engagement with local communities and First Nations.
Confidence	Low	• High degree of uncertainty of the traffic volume related to each ongoing or reasonably foreseeable project and activity. • Traffic management strategies are based on road use and safety requirements that are proven to be effective.

11.3 LAND AND RESOURCE USE

11.3.1 Assessment Indicators and Assessment Parameters

Project effects on land and resource use were assessed by taking into consideration potential changes in commercial and recreational land and resource use, and First Nations culture and land and resource use. Commercial and recreational land and resource use refers to the use of lands and waters for commercial and non-commercial purposes such as forestry, mining, trapping, hunting, fishing and outdoor recreation and tourism activities. Land and resource use in this context also refers to the formal disposition and designation of lands through federal, territorial, or municipal authorities.

First Nations culture and land and resource use refers to Yukon First Nation Citizens and Gwich'in Participants (Gwich'in peoples that are represented by the Gwich'in Tribal Council) cultural practices, beliefs, and values expressed through traditional uses of lands and resources. The ability of First Nations to conduct cultural practices that maintain their cultural identity and support intergenerational knowledge transfer is dependent on access to areas for traditional cultural practices, and the availability and quality of lands and resources for those practices. First Nation culture and land and resources use also includes traditional economic activities related to subsistence activities that provide goods and services to individuals and communities without involving the exchange of money. These activities may include the harvesting of traditional foods, as well as activities such as gathering firewood and using non-timber forest products.

The assessment indicators and parameters selected for the assessment of potential Project effects on the Land and Resource Use VESEC are provided in **Table 3-2** in **Section 3 Methods.**

11.3.2 Project Interactions and Potential Effects

The assessment approach for identifying Project interactions and potential effects involved a systematic review of listed Project components or activities and qualitative analysis for each relevant indicator and assessment parameter of the Land and Resource Use VESEC within the context of existing conditions for the LSA. Identified concerns or interests are included for each potential effect as context. Project components that are expected to interact with the Land and Resource Use VESEC are listed in **Table 3-4**

in **Section 3 Methods**. Most of the interactions with Project components and activities are expected to result in either no effects or minor effects that would be expected to result in no measurable change from existing conditions. These interactions and effects are described in **Section 11.3.2.1 Rationale for No or Negligible Interaction** to provide a rationale for these findings. Interactions that are anticipated to result in a more substantial effect are identified in **Section 11.3.2.6 Interactions.**

11.3.2.1 Rationale for No or Negligible Interaction

Interactions that were identified as having either no or negligible interaction with the Project, and are not assessed further, are described below.

11.3.2.1.1 No Effects on Designated Lands

Concerns related to changes in land use planning or designated lands have been expressed through engagement on the Project with local communities and potentially affected First Nations (see **Section 2 Consultant and Engagement**). These include:

- Comment about the importance of upholding objectives from the North Yukon Regional Land Use Plan; and,
- concern from Vuntut Gwitchin First Nation and Gwich'in Tribal Council related to their Treaty and Aboriginal Rights and expressed interest in advancing discussions related to potential Project effects on their Treaty Rights.

Commercial and recreational land and resource use refers, in part, to the designated and undesignated use of lands. Land use designations are typically established through federal, territorial, or municipal authorities and processes such as land use plans and zoning, tenures and concessions (including license or leases), designated park lands or ecological reserves, or land settlement agreements. The Project overlaps with the boundaries of the North Yukon Planning Region and the Peel Watershed Planning Region and is subject to the approved North Yukon Regional Land Use Plan (2009) and the Peel Watershed Regional Land Use Plan (2019) (Peel Watershed Planning Commission 2022; Government of Yukon and Vuntut Gwitchin Government 2009). The Project is compliant with land use management objectives and policies included in both the North Yukon Regional Land Use Plan (NYRLUP) and Peel Watershed Regional Land Use Plan (PWRLUP).

The Project also overlaps a number of land tenures and concessions, and Yukon first Nation Traditional Territories. The Project is not expected to interact with or result in a change to these existing designated lands. Additional detail is provided below, specific to the Project and overlap with applicable regional land use plans, land tenures and concessions, and land claims agreements.

11.3.2.1.1.1 Regional Land Use Plans

The Project overlaps the boundaries of the North Yukon Planning Region and the Peel Watershed Planning Region. Proposed Project activities are located in Land Management Unit (LMU) 9 (Eagle Plains) of the NYRLUP, and within LMU 7 (Dalglish Creek) of the PWRLUP. See **Appendix 11-A** for figures of the extents of these planning regions**.**

Yukon Regional Land Use Plans were developed in response to Section 11 of the Umbrella Final Agreement and these plans identify how and where land uses may or may not occur (Yukon Land Use

Planning Council 2022). Both NYRLUP and PWRLUP identify land use values, valued environmental components, and management objectives that focus on intended land use for environmental assessment. Both the NYRLUP and PWRLUP propose general land use categories of which the Project overlaps the Integrated Management Area (IMA) Zone 4. The IMA Zone 4 category has a management intent focused on higher levels of land use such as for oil and gas, mining, and other industrial land uses, including road access. The Project is committed to meet the objectives outlined in both the NYRLUP and PWRLUP to effectively manage Project-related effects and address concerns raised through the ongoing engagement on the Project. Further information on consideration of these regional land use plans is provided in **Section 1.7.**

11.3.2.1.1.2 Land Tenures and Concessions

The following is a summary of the land tenures and concessions overlapping or adjacent to the Project footprint within the LSA (or RSA where applicable):

- There are no water licences within the LSA. There are 3 water licences within the RSA, one of which is held by Chance.
- The LSA does not overlap with any placer or quartz mineral claims. The closest quartz claims in relation to the LSA are located approximately 48 km to north and 30 km to the east.
- There are six dispositions within the LSA: a Lease for commercial uses purposes and five Reserves for gravel pit use (Government of Yukon 2021). All are located along the Dempster Highway.
- Neither the LSA nor RSA overlap with any forestry licences.
- There are no parks or protected areas within the LSA. The RSA has a minor overlap (0.03%) with the Ni'iinlii Njik (Fishing Branch) Territorial Park and Conservation Area.
- The LSA overlaps two registered trapping concessions (RTC); RTC 401 and RTC 402. Information was not available about active trapping within these trapping concessions.
- There are no outfitting concessions within the LSA. The closest outfitting concession in relation to the LSA to the south is Outfitting Concession # 2 registered to Blackstone Outfitters Ltd.

Land tenures and concessions are not expected to be affected by the Project. See **Appendix 11-A** for figures of the extents of these tenures and concession areas**.**

11.3.2.1.1.3 Yukon First Nation Traditional Territories and Settlement Lands

Within Canada, Indigenous peoples have constitutionally protected rights and interests related to activities that are an element of practices, customs, or traditions integral to distinctive cultures, and that have continuity with traditions that existed prior to European contact. They may include (but are not limited to) rights and interests related to traditional uses such as habitation, hunting, fishing, trapping, and harvesting. These rights (and treaty rights) are recognized and affirmed by Section 35 of the *Constitution Act (1982)* (Government of Canada 2020).

Within the Yukon, the Umbrella Final Agreement provides a framework for negotiating individual First Nation Final Agreements and Self-Government Agreements (Government of Yukon 2018). Vuntut Gwitchin First Nation, Gwich'in Tribal Council, the First Nation of Na-Cho Nyäk Dun, and Tr'ondëk Hwëch'in First Nation have signed Final Agreements and Self Government Agreements with the Government of the Yukon and the Government of Canada that outline the laws, powers, and governance structures that each First Nation

uses to govern its Citizens and lands (Government of Yukon 2019). These agreements include the designation and definition of Settlement Lands, which are lands owned and managed by a Yukon First Nation, and Traditional Territory that individual First Nations have traditionally used and have rights and interests within.

The Project footprint overlap any First Nation Settlement Lands. The Project footprint does border portions of the Vuntut Gwitchin First Nation Class A Settlement Lands to the east and southwest, and Tr'ondëk Hwëchin Class A Settlement Lands to the southwest. The Project footprint does overlap the Traditional Territories, as defined in Land Claim Agreements with Yukon First Nations, of the Tetl'it Gwich'in Council, Tr'ondëk Hwëchin, the First Nation of Na-Cho Nyäk Dun, and Vuntut Gwitchin First Nation.

The majority of the Project activities and components are located in the Traditional Territory of the Vuntut Gwitchin, the First Nation. Tetl'it Gwich'in Council Traditional Territory overlaps a portion of the Project footprint in the southeast, including a Secondary Use Area along the Dempster Highway and a small portion of Primary Use Area near Dalglish Creek. Most of the Traditional Territories for the Tr'ondëk Hwëchin and the First Nation of Na-Cho Nyäk Dun occur to the south and southwest of the Project footprint, respectively (Government of Yukon 2021). See **Appendix 11-A** for figures of the extents of these Settlement Lands and Traditional Territories**.**

The Project activities and components will occur within Traditional Territories of potentially affected First Nations. Assessment of effects on cultural use of Traditional Territories will be discussed in the subsequent analysis of First Nations culture and land and resource use.

11.3.2.1.2 No Effects on Availability and Abundance of Resources for Commercial Use

Project-related activities and components have the potential to affect the availability and abundance of resources used for commercial purposes within the Project footprint through vegetation clearing or potential disturbance to wildlife species or habitat. Changes to the availability and abundance of resources for commercial land and resource uses such as forestry, mining, oil and gas, hunting, and trapping were assessed. Concerns about the Project-related effects on the availability and abundance of resources for commercial use have been expressed through engagement on the Project with local communities and First Nations (see **Section 2 Consultation and Engagement**). These focused on increased access of predatory species to areas used for commercial purposes, as well as reduced opportunity to access a historic trapline that overlap the Project footprint.

Based on the assessment of land tenures within the LSA (see **Section 11.3.2.1.1 Regional Land Use Plans**), no forestry licences, outfitting concessions, placer claims, or quartz claims were identified, indicating no activities related to these commercial activities are occurring or planned for the area. The Project footprint encompasses approximately 2,400 km² of oil and gas claims held by Chance Oil and Gas Ltd. Two RTCs (i.e., RTC 401 and RTC 402) overlap the Project footprint. This indicates that there is the potential for commercial land and resources related to trapping within the LSA. Information related to the current level of trapping activity within the Project footprint was not available at the time of writing the Project Proposal; however, information gathered through interviews with key informants (including representatives from First Nations and local communities) suggests that minimal to no commercial trapping is occurring within the Project footprint (see **Appendix 11-A**).

As the LSA does not include active commercial land uses, beyond oil and gas exploration which is the focus of the Project Proposal, no Project-related effects on the abundance and availability of resources for commercial uses in the LSA are expected. Therefore, these effects are not carried forward in the assessment.

11.3.2.1.3 Negligible Effects on the Land Area and Access for Commercial and Recreational Use

Project-related components and activities have the potential to affect the land available for, and access to, areas of commercial and recreational uses within the LSA as the Project will involve the temporary use of lands for seismic exploration, and the sustained use of land areas for winter road access, camp facilities, well sites, and surface infrastructure. The Project will also involve temporary restrictions on public access within the LSA near well sites and along winter access for safety reasons. Concerns about Project-related effects on land use areas and access have been expressed through engagement on the Project with local communities and First Nations. These include:

- comment about a historic trapline in the southern portion of the Project and concerns over reduced opportunity; and,
- concern about resource road access and regulation.

While the locations and extent of Project-related exploration within the Project footprint are not certain at the time of the assessment due to the exploratory nature of the Project, there is potential for the use of up to approximately 7,019 ha from the development of the winter roads and seismic features, well sites, camps, and areas for surface infrastructure (see **Section 7 Vegetation** for further details). This represents approximately 2.8% of the 256,975 ha of the LSA.

Based on the assessment of land tenures (see **Section 11.3.2.1.1 Regional Land Use Plans**), the LSA does not include active commercial lands uses, beyond oil and gas development which is the focus of the Project Proposal. As the LSA does not include active commercial lands use, beyond oil and gas development, no Project-related effects on the land area and access for commercial uses in the LSA are expected.

There is the potential for the Project to affect the land available for, and access to, areas for recreational use within the LSA due to the use of lands for Project activities and restrictions on public access. While there is the potential for recreational use of the LSA for activities such as fishing or hunting, based on available information, a small amount of recreational use occurs in the LSA with most being focused along the Dempster Highway (see **Appendix 11-A**).

Historical operations in the LSA by Chance have observed that access restrictions do not effectively prevent the public from accessing the Project footprint and it is expected that enforcement of restricted access will be focused on localized areas during active exploration. Within the LSA, there are a number of existing trails, access roads, and other existing seismic cutlines that will not be affected by Project-related activities or access restrictions and may continue to be used. There is the potential that the uncontrolled portions of Project-related access roads may be used and increase accessibility within the LSA, as land users are often attracted to the development of new resource roads to access remote areas.

Considering the limited amount of commercial and recreational activity that is understood to be currently occurring within the LSA, the small area of the LSA (2.8%) that will be affected by Project-related exploration, and that accessible travel routes will continue to be available throughout the LSA. It is anticipated that the overall land available for, and access to areas for recreational use will experience an incremental change from existing conditions. This potential effect is considered to be negligible and is not carried forward for further assessment.

Potential effects on access by commercial and recreational users (including tourists) on the North Klondike and Dempster Highways from Project exploration activities are assessed in **Section 11.2 Community Infrastructure and Services**.

11.3.2.1.4 Negligible Effects on Resource Availability, Abundance, or Quality for Subsistence Use by First Nations

The ability of Yukon First Nation Citizens and Gwich'in Participants to conduct cultural practices based on customs, beliefs, and values (such as subsistence use) is dependent, in part, on the availability of quality lands and resources to support those practices. Lands and resources in the LSA are important to the Gwich'in Tribal Council, Tr'ondëk Hwëchin, the First Nation of Na-Cho Nyäk Dun, and Vuntut Gwitchin First Nation for subsistence activities including hunting, trapping and harvesting for cultural purposes.

Yukon First Nation Citizens and Gwich'in Participants harvesting of wildlife, fish and vegetation is dependent upon the availability, abundance and quality of valued species that support subsistence activities. Concerns about the Project-related effects on harvesting and subsistence activities have been expressed through engagement on the Project with local communities and First Nations, including:

- concerns from Gwich'in Tribal Council related to Project effects on trapping, caribou and moose hunting activities, and wildlife on which Gwich'in depend for food;
- concerns about access roads and effects on water and fish;
- concerns from the Vuntut Gwitchin First Nation about a potential effect on the quality of Traditional Territory and the potential effect on the livelihood of Vuntut Gwitchin First Nation;
- concerns from Trondëk Hwëch'in related to trapping and caribou hunting and caribou, which has a high value as traditional food and for cultural and spiritual wellbeing; and,
- concerns about reduced opportunity for trapping on the historic trapline in the southern portion of the Project footprint.

11.3.2.1.4.1 Pattern of Subsistence Use Within the Local Study Area

The following is a summary of Yukon First Nation Citizens and Gwich'in Participants subsistence uses within the LSA, as described by available information, to provide context for the assessment of Project effects. Further details are available in **Appendix 11-A**. This information indicates that Vuntut Gwitchin First Nation Citizens and Gwich'in Participants currently use areas in the LSA for cultural purposes including wildlife, fish and vegetation harvesting for subsistence.

Vuntut Gwitchin First Nation Citizens depend on the Porcupine Caribou Herd to maintain their traditional way of life and continue to actively participate in traditional subsistence harvesting activities for harvesting of caribou, moose, waterfowl, fish and berries/edible plants. Caribou harvesting may occur in the LSA but is identified as being most focused north of the LSA near Old Crow. The LSA is identified as has having good quality moose habitat and is used for moose harvesting by Vuntut Gwitchin First Nation Citizens

although the majority of moose hunting effort takes place in the vicinity of Old Crow. The lands within the LSA have been a major fur trapping area for Vuntut Gwitchin First Nation Citizens as it is a productive area for fur bearers, like marten. Trapping has historically been focused near Old Crow and in the Whitestone area to the southwest of the LSA, but trapping is identified as occurring around the Dempster Highway corridor. Vuntut Gwitchin First Nation Citizens mainly fish along the Lower Porcupine River and areas to the north of the LSA, as well as in the Whitestone area to the west. Historic fish trapping locations occurred along the Lower Porcupine River and Chance Creek near Whitestone Village and Ellen Creek areas in the vicinity of Eagle Plains. Vuntut Gwitchin First Nation Citizens have stopped fishing in some historic fishing sites due to the shortages of fish and changes in fish habitat in some creeks within their Traditional Territory. Vuntut Gwitchin First Nation Citizens also rely on harvesting plants as an important food source, as medicinal plants for treating illnesses and diseases, and as material for wildlife harvesting such for traps or for drying meat. Key areas for berries and medicinal plant gathering have been identified around the southeast corner of the LSA near Dalglish Creek, Enterprise Creek, and the Dempster Highway.

Trapping furbearers, hunting caribou, and harvesting plants, berries, roots, and pitch are all key subsistence harvesting practices that Gwich'in Participants have traditionally engaged in within the LSA. During engagement on the Project with local communities and First Nations, Gwich'in Tribal Council representatives stated that the Project footprint is a known hunting area for moose and barren-ground and Woodland Caribou. Gwich'in Tribal Council representatives noted the Project footprint overlaps with Tetl'it Gwich'in Council traplines and that trapping activity in the area focuses on marten, lynx, beaver, and wolf. It was acknowledged that Gwich'in Participants of Fort McPherson typically hunt moose and pick berries along the border of the Yukon and NWT, as well as along the Dempster Highway. Subsistence fishing activities for Gwich'in Participants was characterized as being focused on the Peel and MacKenzie Rivers located outside of the LSA.

Tr'ondëk Hwëch'in Citizens conduct subsistence harvesting within their Traditional Territory throughout the year to take advantage of migrating animals and fish, harvesting plants in season and trapping in winter to collect thick furs. Available information did not identify specific subsistence use areas within the LSA for either of the Tr'ondëk Hwëch'in First Nations Citizens or First Nation of Na-Cho Nyäk Dun Citizens.

See **Appendix 11-A** for additional information on First Nations subsistence use.

11.3.2.1.4.2 Effects on Vegetation, Wildlife and Fish Species that Support Subsistence Use

The following is a summary of potential effects on vegetation, wildlife and fish species to support the assessment of Project effects to the availability and quality lands and resources to support subsistence use.

Based on the assessment of the **Section 7 Vegetation**, there is a potential for interaction between Project activities and vegetation within the LSA that are valued by Yukon First Nation Citizens and Gwich'in Participants for subsistence harvesting (e.g., tamarack, willow, berries, roots). Trees and tall shrubs will be cleared for access roads and well sites, but winter ground preparation will protect the active ground vegetation layer and preserve saplings and small shrubs. Low impact seismic methods will substantially reduce vegetation removal, including large trees. Constraints mapping will minimize effects to areas identified as high-value wetlands and riparian areas. Existing disturbances, burn areas, and natural open areas will be used where possible rather than disturb existing vegetation (e.g., CPF surface infrastructure

within the disturbed area near the main camp). Project activities related to access roads and well sites will disturb or remove vegetated areas within the LSA, but proposed management measures and practices will minimize the potential effects on the availability and abundance of tree and plant species. The overall availability and abundance of trees and plants for traditional cultural food sources, medicinal uses, and materials are expected to experience a minor change from existing conditions due to Project-related clearing that is predicted to result in a negligible effect on the ability of First Nations to harvest culturally important vegetation for subsistence activities within the LSA.

Based on the assessments in **Section 8 Caribou** and **Section 9 Wildlife and Wildlife Habitat,** there is a potential for interactions between Project activities and wildlife or wildlife habitat within the LSA, which are considered important for Yukon First Nation Citizens and Gwich'in Participants subsistence harvesting (e.g., marten, moose, and caribou). Localized effects on wildlife distribution may occur from the potential for avoidance by wildlife in and near the Project footprint due to the disturbance from active exploration activities as well as minor effects on wildlife habitat availability from vegetation clearing. The Project will occur during the winter when many wildlife species are absent in the LSA (e.g., migration out of the region by birds, denning by bears) and/or less sensitive to disturbance (e.g., caribou). Project activities are expected to affect moose habitat availability and use and possibly have a negligible effect on mortality risk. Project activities are scheduled to occur when caribou may be present in the LSA during the fall and winter; however, caribou do not use the Project footprint every year, and when they do, it is typically for short periods (up to approximately two weeks). When caribou are present, the Project may affect localized movements within the LSA. Potential localized effects on wildlife are not expected to represent a change to Yukon First Nation Citizens and Gwich'in Participants ability to harvest culturally important wildlife species for subsistence within their Traditional Territories.

Based on the assessment in **Section 6 Fish and Fish Habitat**, there is no measurable anticipated effect between Project activities and fish and fish habitat. Although there are abundant waterbodies in the Project area, many of which are expected to support fish in the warmer months, most Project activities will occur in the winter when most of these waterbodies are frozen, and fish are not present in the LSA. Mitigation measures related to fish and fish habitat are detailed in **Section 6 Fish and Fish Habitat**.

Based on the assessment in **Section 11.4 Community Health and Wellbeing**, and the evaluation of changes in traditional food quality, there is a potential for the Project to affect the quality of traditional food sources (e.g., fish, moose, berries and plants) due to contamination of environmental media (i.e., surface water, groundwater, soil, air quality, sediments) that may affect the overall health of culturally important species for subsistence use. Limited information was available on existing tissue quality or contamination of wildlife, fish, and plant or vegetation species. The degree of potential effects on the quality of vegetation, wildlife, or fish is expected to be in alignment with potential Project-related effects on air, water, vegetation and soil disturbance, and water sources, with consideration for bioaccumulation and biomagnification potential.

As the Project's activities are largely limited to the winter, it is assumed that the Project will result in minimal soil and vegetation disturbance, minimal sedimentation and dust emissions, or effects on surface and groundwater that would be a source of contaminates and result in an exposure risk to plants, wildlife or fish. Consequently, the effects on the quality of vegetation, wildlife, and fish species for subsistence use are anticipated to be negligible.

11.3.2.1.4.3 Effects on Subsistence Use

Based on the predicted effects on vegetation, wildlife and fish species provided previously, the presence and distribution of wildlife is expected to be minimally changed, characterized by the potential for moose and caribou to temporarily avoid localized areas of the Project footprint related to active seismic line preparation and drilling sites. It is anticipated that the overall availability of wildlife species for subsistence harvesting activities would be consistent with existing conditions. Similarly, the availability of trees and plants for subsistence harvesting is anticipated to experience a minor change from existing conditions.

The availability of fish is not expected to be affected by the Project. Effects on the quality of vegetation, wildlife, and fish species for subsistence use are anticipated to be negligible. As a result, Project-related effects on resource availability, abundance, or quality for subsistence use by First Nations in the LSA are considered to be negligible. This potential effect is not carried forward for further assessment.

11.3.2.1.4.4 Related Effects on First Nations Culture and Traditional Economy

First Nations values related to cultural identity and cultural activities such as the transmission of the Traditional Knowledge are often interconnected with the ability to practice subsistence use. It is expected that the negligible effects on First Nations subsistence use will allow for the continued harvesting of culturally important wildlife, fish, and plants for subsistence use and will not interfere with the aspect of cultural identity of the Vuntut Gwitchin First Nation, Tr'ondëk Hwëch'in, Gwich'in Tribal Council and First Nation of Na-Cho Nyäk Dun or the transmission of Traditional Knowledge related to subsistence use.

Concern about potential perceived adverse effects on the availability and quality of resources for subsistence activities may occur for First Nations users who harvest within the LSA despite the application of mitigation measures. First Nations values related to the condition of lands and wildlife are often interconnected with a broader sense of community health and wellness. An effect, actual/or perceived, to one value may result in effects on other cultural values. Effects on health and wellbeing are assessed in **Section 11.4 Community Health and Wellbeing.**

Considering the negligible effects on the availability, abundance and quality of resources for subsistence activities within the LSA, no effects on the traditional economy that rely on subsistence activities are predicted. The Project is not expected to reduce Gwich'in Tribal Council Participants, or Vuntut Gwitchin First Nation, Tr'ondëk Hwëch'in, and First Nation of Na-Cho Nyäk Dun Citizens' participation and contribution in traditional economy activities.

11.3.2.2 Interactions

Project components and activities interactions with land and resource use were evaluated following the approach in **Section 3.1.4.1 Project Interactions and Potential Effects.** Project components and activities that have the potential to interact with land and resource use are shown in **Table 11-10**. Three potential effects on land and resource use are expected. The pathway for potential adverse effects is described in the following sections.

Table 11-10. Expected Interactions between Land and Resource Use and the Eagle Plains Exploration Project and Resulting Potential Effects

Project Component / Activity	Potential Effect #1	Potential Effect #2	Potential Effect #3
Engagement	0	0	0
Seismic Exploration	2	2	2
Drilling Exploration	2	2	2
Extended Flow Testing (EFT)	1	1	1
Well Maintenance (Workovers)	0	0	0
Winter Access Roads	2	2	2
Mix Bury Cover (MBC)	2	2	2
Central Processing Facility (CPF)	2	0	2
Airstrip	1	1	1
Water Withdrawal	0	0	0
Transportation	1	1	1
Camp	1	1	1
Reclamation and Closure	1	1	1

Notes:
0 = no interaction. A rationale for no effects is addressed in **Section 11.3.2.1 Rationale for No or Negligible Effects**.
1 = minor interaction with land and resource use is possible, but small immeasurable effect. A rationale for negligible effects is addressed in **Section 11.3.2.1 Rationale for No or Negligible Effects**. This rating does not lead into residual effects characterization.
2 = substantial interaction with land and resource use, designates a more detailed assessment of potential effects. Carry forward into residual effects characterization.

11.3.2.3 Change in Environmental Conditions for Recreational Use

Concerns about the Project-related effects on environmental conditions have been expressed through engagement on the Project with local communities and First Nations. These include the following:

- concerns about visual effects on motorists travelling along the Dempster Highway; and,
- concerns about human land use-related disturbances such as noise, odour, and light and potential mitigation measures.

Local communities and First Nations have also expressed support for the monitoring for air quality and emissions.

The following is a summary of the Project's existing environmental setting and relevant Project components that are anticipated to interact with air quality, the acoustic environment, or the visual landscape and affect the experience of recreational users in the LSA.

11.3.2.3.1 Air Emissions

No major sources of anthropogenic air pollutants, such as quarrying, industrial activity, or incineration are located within the LSA, although some sources are located within the broader regional context (e.g., mining

and settlements). Sources of air pollutants within the LSA include vehicles along the Dempster Highway (e.g., exhaust and dust), generators used at the Chance Camp, and possible remote work sites that minimally contribute to the existing local air quality. Wildfire smoke is a potential seasonal source of particulate matter and other air pollutants that are capable of travelling long distances and reduce the air quality within the region. For the purposes of this assessment, the LSA is assumed to have clean air quality with minimal pollutants.

Air emissions may occur from Project components and activities that could affect the environmental setting for recreational users in the LSA. Airborne particulates in the form of fugitive dust are anticipated to result primarily from activities occurring in summer under dry conditions, such as the use of vehicles on roads or seismic lines, or from excavation of the MBC sump area. With the exceptions of seismic exploration, Project activities will occur mostly during the winter months when soils are frozen and site access occurs along winter access. As a result, fugitive dust produced by the Project is anticipated to be minimal and to only occur during the summer.

Flaring related to EFT is a potential source of short-term air emissions. It consists of burning off natural gas at height (up to approximately 30 m) to minimize possible interactions with receptors on the ground, although some odours may be associated with flaring as well as noise and light disturbances (Yukon Environmental and Socio-economic Assessment Board 2020).

Air emissions may occur from Project activities that involve the combustion of fossil fuels (i.e., exhaust) during seismic exploration, drilling, reclamation, and closure activities. Sources of exhaust may include mobile sources such as light-duty trucks, ATVs and snowmobiles, heavy equipment (e.g., mulchers and Low-Impact Seismic [LIS] drills), air transportation (i.e., airplanes and helicopter), as well as stationary sources such as a drilling rig and camp equipment (e.g., generators, boilers). Air emissions in the LSA from these sources are expected to be localized to areas where equipment is being operated. Once mobile or stationary equipment has moved to a site, air quality is expected to return to baseline conditions within a brief period (e.g., a few days).

Quantification of air emissions from combustion of fossil fuel sources identified above are not characterized at this time but will be reported in accordance with relevant territorial and federal air emission regulations. Based on previous air quality assessments for the Project area, air quality effects from the mobile and stationary sources are anticipated to be minor and localized in areas of active road construction, well sites, and camp operations (Yukon Environmental and Socio-economic Assessment Board 2020).

11.3.2.3.2 Noise

The existing acoustic environment within the LSA is characterized by a generally low level of ambient noise. Natural ambient noise sources within the LSA include wildlife and weather (e.g., wind). Anthropogenic noise sources within the LSA include vehicle traffic along the Dempster Highway, operations at the Chance Camp and may include occasional ATV or skidoo engines or overhead air traffic. Summer is likely to experience noise levels related to increased seasonal traffic and construction or maintenance work along the Dempster Highway. For the purposes of this assessment, the existing ambient noise levels within the LSA are predicted to be low overall and have been conservatively characterized by baseline rural noise levels of

between 35–45 decibels (dBA)[24] as applied in other assessments and established guidelines (British Columbia Energy Regulator 2023).

Noise from Project-related activities is expected to occur within the LSA due to heavy equipment and vehicle use, exploration drilling, seismic detonation, diesel power generation, and construction activities. Noise related to drilling at well sites will be a key source; drilling rigs have a noise level of approximately 68 dBA at 100 m from source (Noise Monitoring Services 2020). Noise from diesel generators (approximately 50 dBA at 100 m from source) will occur at well sites as well as at the Chance Camp[25] (AMEC 2015). Construction of the CPF and MBC will generate noise from the use of heavy equipment (truck, graders, pneumatic tools) and activities related to site preparation and assembly of materials (approximately 73 dBA at 100 m from source) (AMEC 2015).

Temporary noise generated during construction is expected to occur predominately during the summer. Noise generation from detonation during seismic testing will be minimal as it will occur below the surface. The regular movement of aircraft transporting crews during the winter and the summer seismic program will also generate intermittent, but potentially perceptible, noise overhead. Noise from flaring may occur when large volumes of high-pressure natural gas are being flared. While Project-related activities may result in an evident increase in noise levels[26], perception will be dependent on the receptors locations relative to the noise source as the level of sound decreases with distance from the source. As a result, the perception of most sources of Project-related noise are anticipated to be limited to the area in proximity to Project activity. Recreational users travelling along the Dempster Highway will have the highest potential for exposure to noise from the Chance Camp and MBC sites (i.e., excavation) as activities at these Project sites are located near the roadway, but Project drilling and seismic exploration activities occurring throughout the more remote portions of the LSA will be less perceptible due to the sound diminishing over long distances. Inversely, recreational land users may come into closer proximity to sources of noise from exploration activity and well sites. Considering the small amount of recreational use that occurs in the LSA, exposure to increased noise is expected to be minor and infrequent.

The overall incremental increase in noise generated by Project components and activities is not anticipated to be evident to most recreational users in the LSA, considering that drilling and seismic exploration activities will occur in remote areas outside the areas where recreational activities within the LSA are conducted. Perceptible noise for most recreational users will occur closer to the Dempster Highway (i.e., near the surface infrastructure at the CPF and MBC site) where there are existing noise sources. It is anticipated that the incremental increase in noise from the Project, while audible, would not be easily discernible to most recreational users within the existing ambient noise level of the LSA.

11.3.2.3.3 Visual Disturbance

The predominately natural landscape setting of the LSA is composed of a large expanse of mostly flat to rolling sub-arctic terrain, covered by generally sparse forests and scattered wetlands. Built features include

[24] Decibels are a unit describing the amplitude of sound commonly used to express ambient sound levels.
[25] Noise from generators already occurs during operations at the Chance Camp and, while it may be perceivable, is not considered to be an incremental noise effect related to the Project (Victoria Gold Corporation and Stantec 2010).
[26] Generally, for each +/- 10 decibel change in sound level, the sound intensity increases/decreases 10 times and is perceived as twice/half as loud.

the gravel surfaces of the Dempster Highway and resource roads, as well as a network of seismic cut lines throughout the forested landcover. The scenic value of the landscape is a key attractor to recreational users and tourists in the region. The visual landscape is further described in **Appendix 11-A.**

The landscape of the Project footprint will experience visual disturbances related to the clearing of vegetation for access and seismic exploration, the introduction of built features (e.g., wellsite surface infrastructure), and related safety and security lighting that may be visible from viewing locations within the LSA. Visual disturbance from exploration activities will occur progressively throughout the Project footprint in relation to the clearing for new access, and the construction of up to 30 well sites over 10-years. Well sites will include surface infrastructure (e.g., boilers, incinerators, ancillary trailers, storage units and tanks) and tall structures (i.e., up to approximately 30 m) such as the drill rig derrick and flare stack that may be visible above the surrounding canopy of vegetation. **Photo 1-8** in **Section 1 Details of the Proposed Project** provides an illustration of the typical drill rig and wellsite components and lighting. During drill stem testing, gas may be control-burned through the flare stack and create a temporary but visible light emission that would likely attract the attention of viewers.

Construction of the MBC will involve clearing of an area of approximately 6 ha to prepare the site. The development of the MBC site will include landform modifications from excavation, berms and stockpiling of materials. Similarly, the construction of the CPF adjacent to the camp will result in the visibility of additional surface infrastructure (e.g., separators, flare stacks, storage tanks) at the southernmost end of the main camp and related safety and security lighting.

It is anticipated that temporary visual disturbances will occur related to the presence of construction equipment and materials at the Chance Camp site during the early construction period, and the presence of Project vehicles for vegetation clearing, drilling, and well maintenance activities along Project access during the exploration activities. The movement of aircraft using the airstrip during the winter, as well as aircraft and helicopters during the summer seismic program, would be temporary and may attract the attention of recreational users.

The potential for public viewing of Project activities is expected to be minimal due to its remote nature and a relatively low amount of recreation and tourism activities occurring in the LSA. Viewing opportunities are most likely related to recreational users and tourists travelling through the LSA along the Dempster Highway. The overall visual disturbance of the Project components and activities are not expected to be readily evident to most viewers along the Dempster Highway considering the scale of Project components and visibility over long viewing distances across the Project footprint; visual elements of the landscape are less discernible and prominent the farther they are from the observer. Visual disturbances that will occur closer to the Dempster Highway (i.e., near the Chance Camp area and MBC site) will likely be more evident but will be partially screened from view.

Lighting of the surface infrastructure at the CPF, well sites (and related to flaring events) and from Project vehicles (e.g., mulchers, LIS drills, light-duty trucks) will likely be most visible during the winter and periods of low light and is likely to attract the attention of viewers within an otherwise naturally dark nighttime environment. It is anticipated that most Project components and activities would blend into the existing visual landscape of the LSA and is expected to result in minimal disturbance to viewing opportunities LSA.

The overall minor increases in air emission, noise level and visual disturbance are expected to be perceivable and have the potential to affect the environmental conditions valued by recreational users as a

setting for outdoor activities within some portions of the LSA. However, these incremental effects are not expected to change the overall experience of recreational users from existing conditions.

11.3.2.4 Change in Land Area and Access for First Nations Cultural Use

The Project footprint overlaps the Traditional Territories of the Vuntut Gwitchin First Nation, Tr'ondëk Hwëch'in, Gwich'in Tribal Council and First Nation of Na-Cho Nyäk Dun. The ability of Yukon First Nation Citizens and Gwich'in Participants to conduct cultural practices based on customs, beliefs, and values is dependent, in part, on access to and area of their Traditional Territories for cultural use. It has been identified through available information, that lands and waters in the LSA are important for cultural activities including habitation and other traditional and cultural purposes. Concerns about the Project-related effects on cultural use areas and access have been expressed through engagement on the Project with local communities and First Nations. These include:

- concerns from Gwich'in Tribal Council related to Project effects on trapping and hunting activities, and the ability to travel and use the land for traditional purposes;
- comment highlighting presence of documented important traditional places and traditional trails and travel routes across the Project footprint;
- concerns about access roads (e.g., Blackie Road) and both increased access to the Project area and use by ATV and skidoo traffic; and,
- concerns from the Vuntut Gwitchin First Nation about the effect on the quality of Traditional Territory and effect on the livelihood of Vuntut Gwitchin First Nation.

11.3.2.4.1 First Nations Cultural Use Within the Local Study Area

The following is a summary of Yukon First Nation Citizens and Gwich'in Participants cultural use areas and routes, as described by available information, to provide context for the assessment of Project effects. Further details are available in **Appendix 11-A.** This information indicates that Vuntut Gwitchin First Nation Citizens and Gwich'in Participants have traditionally and/or currently use areas in the LSA for cultural purposes including habitation, and land navigation and trails related to subsistence harvesting.

Historically, Vuntut Gwitchin First Nation Citizens had a nomadic lifestyle in their Traditional Territory dictated by the movement of food sources and harvesting times. They were known to have semi-permanent dwellings at many sites throughout the LSA as they followed the Porcupine Caribou and trapped. Vuntut Gwitchin First Nation Citizens established settlements at Driftwood Village, Johnson Creek Village, and Whitestone Village adjacent to the Project footprint, as well as cabins in the Old Crow region. Whitestone is a traditional village site and one that Vuntut Gwitchin First Nation Citizens continue to visit annually for hunting and fishing activities. It is stated that there are Vuntut Gwitchin First Nation Citizens with camps along the Dempster Highway, some in the Eagle Plains area, that are still used. It has been noted that Vuntut Gwitchin First Nation Citizens do not frequent the Project footprint as often as they have historically, due to its distance from Old Crow.

Vuntut Gwitchin First Nation Citizens have used trails to hunt, trap and trade within their Traditional Territory. The Vuntut Gwitchin Final Agreement identifies heritage routes from Old Crow to Whitestone Village and Old Crow to Fort McPherson. Vuntut Gwitchin First Nation Citizens access most of their traditional hunting and gathering areas around Eagle Plains by boat and snowmobiles. The Eagle River, located to the east and within the south portion of the LSA, has been identified as a key travel corridor for Vuntut Gwitchin First

Nation Citizens. The establishment of the Dempster Highway in the late 1970s created easier access to locations in Eagle Plains for cultural harvesting purposes.

The Primary and Secondary Use Areas defined in the Gwich'in Settlement Region includes areas in the Yukon that overlap the LSA. Available information did not identify habitation sites within the LSA for Gwich'in Participants. The Dempster Highway follows a traditional Tetl'it Gwich'in Council trail for part of the highway's length. Available information indicates that most cultural travel routes used by Gwich'in Participants are located outside the LSA near the Yukon and NWT border. The Peel, Arctic Red, and Mackenzie rivers, to the northeast of the LSA, are identified as key travel routes for Gwich'in Participants to access fish camps and harvesting areas and link different areas of their Traditional Territory.

First Nation of Na-Cho Nyäk Dun Citizens have historically had a semi-nomadic lifestyle, moving across their traditional territory to follow seasonal rounds[27] for hunting, fishing, and gathering food. Tr'ondëk Hwëch'in Citizens conduct subsistence harvesting within their Traditional Territory taking advantage of migrating animals and fish, harvesting seasonal plants and trapping. Tr'ondëk Hwëch'in Citizens travelled between harvesting sites but often returned to the same harvesting camps and established seasonal settlements. Available information did not identify habitation sites, travel routes and trails, or specific subsistence use areas within the LSA for either First Nation of Na-Cho Nyäk Dun or Tr'ondëk Hwëch'in.

Additional information on First Nations Cultural Use is referenced in **Appendix 11-A**.

11.3.2.4.2 Effects on Cultural Use

The Project will involve the temporary reduction of land area in the LSA available for Yukon First Nation Citizens and Gwich'in Participants cultural use from the incremental production of the seismic lines and seismic exploration activity, and the sustained use of land areas for winter roads, camp facilities, well sites and the surface infrastructure. The Project will establish a maximum of 200 km of active winter access roads (e.g., new and existing access roads) per season within the Project footprint. Project activity on the winter access roads will be related to winter road clearing, transport of drilling rigs and site construction material, and the daily transport of workers from the main Chance Camp or remote camp sites. While the locations and extent of Project-related activities within the LSA are not certain at the time of the assessment due to the exploratory nature of the Project, there is potential for the use of up to approximately 7,019 ha from the establishment of the winter roads and seismic features, well sites, camps, and areas for surface infrastructure (see **Section 7 Vegetation** for further details). This represents approximately 2.8% of the 256,975 ha of the LSA.

There is the potential for a change in the area of land available for Yukon First Nation Citizens and Gwich'in Participants cultural use within the LSA due to the temporary and sustained use of lands for the Project's activities. A small percentage of overall land area of the LSA is expected be disturbed. This area will be progressively explored over 10 years with areas of active exploration representing a smaller proportion of the total affected area at any given time. As a result, Yukon First Nation Citizens and Gwich'in Participants who currently use the LSA may experience a minor decrease in the availability of lands within the LSA for cultural purposes.

[27] Seasonal Rounds are related to the natural events and cycles that take place over the course of a year and are often related to planning harvest times through observations in nature.

The Project will involve the temporary restriction to public access within the LSA. Because of the potential to encounter sour gas (H_2S), access to well sites will be restricted to authorized personnel only. Winter roads will be restricted from public access for safety reasons as well. Historical exploration by Chance in the LSA have observed that this does not effectively prevent the public from accessing the Project footprint and it is expected that enforcement of restricted access will be focused on localized areas during active clearing, drilling, and transportation of equipment, materials and workers.

There is the potential for a change to access by potentially affected Yukon First Nation Citizens and Gwich'in Participants to cultural use areas due to public access restrictions to be enforced by Chance for safety reasons. Beyond identified heritage routes and trails, it is not certain where access to culture use areas may explicitly occur within the LSA. It is assumed, for the purposes of this assessment, that access to cultural use areas will occur by established routes or seasonal means that provide relatively easy travel (e.g., by ATV or skidoo). Within the LSA, there are a number of established travel routes, such as existing trails, access roads, and other existing seismic cutlines, that will not be affected by Project-related activities or access restrictions and may continue to be used. There is also the potential that the uncontrolled portions of Project-related access roads may be used and increased accessibility within the LSA as land users are often attracted to the development of new resource roads to access remote areas.

Considering the small amount of Yukon First Nation Citizens and Gwich'in Participants cultural use identified as occurring within the LSA, the small area of the LSA (2.8%) that will be affected by Project-related exploration, and that accessible travel routes will continue to provide access throughout the LSA, it is anticipated that Yukon First Nation Citizens and Gwich'in Participants will experience a small decrease in the availability of lands and temporary interruptions of access within the LSA for cultural purposes that will represent an minor change from existing conditions. This potential effect may be more prominent for particular cultural use areas or travel routes used by potentially affected First Nations within the LSA as the Project progresses, but the overall effect is considered consistent within the existing pattern of available land and access that Yukon First Nation Citizens and Gwich'in Participants currently use to practice rights and interests related to traditional practices.

Concern about potential perceived adverse effects on access to and area for cultural use within potentially affected First Nations Traditional Territories in the LSA may remain despite the application of management strategies. Yukon First Nation Citizens and Gwich'in Participants values related to the availability of and access to land and waters for cultural use are often interconnected with a broader sense of community health and wellness. An effect, actual/or perceived, on one value may results in effects on other cultural values. Effects on health and wellbeing are assessed in **Section 11.4 Community Health and Wellbeing**.

11.3.2.5 Change in Environmental Conditions for First Nations Cultural Use

Collectively held customs, beliefs, and values of individual Yukon First Nation Citizens and Gwich'in Participants are recognized as being linked to specific places and environments. Available information about cultural use of the LSA expressed that the environment surrounding the Project is valued for the way it supports cultural identity and cultural activities such as the transmission of the Traditional Knowledge. Consequently, the ability of potentially affected First Nations to maintain their cultural identity is partially dependent on the environmental conditions that support cultural practices.

Concerns about the Project-related effects on cultural identity and transfer of Traditional Knowledge, or sensory effects which may adversely affect the experience of First Nations cultural use have been expressed through engagement on the Project with local communities and First Nations. These include:

- interest in the process for protecting oral history;
- Gwich'in Tribal Council identified that the landscape is a key cultural value;
- concern about human land use-related disturbances such as noise, odour, light, and visual effects;
- concern related to the seismic program's noise effects; and,
- concerns about the effect of exploration on the quality of the Traditional Territory of Vuntut Gwitchin First Nation.

The following is a summary of the Project's existing environmental setting**,** and relevant Project components and/or activities that are anticipated to interact with the experience of First Nations cultural practices in the LSA. Details of Yukon First Nation Citizens and Gwich'in Participants cultural use in the LSA are available in **Section 11.3.2.4.1**, and in **Appendix 11-A.**

Available information on Yukon First Nation Citizens and Gwich'in Participants cultural use provides some perspective on the cultural value of a landscape context to that precedes the current pattern of industrial exploration activity and transportation infrastructure within the LSA. As such, it is acknowledged that Yukon First Nation Citizens and Gwich'in Participants may be vulnerable to changes in the environmental conditions that further alter the natural character of the LSA, and that Yukon First Nation Citizens and Gwich'in Participants may experience differential effects related to air quality, noise, or visual disturbance of the landscape that support cultural use, the transmission of Traditional Knowledge, and cultural identity.

11.3.2.5.1 Air Emissions

No major sources of anthropogenic air pollutants, such as quarrying, industrial activity, or incineration are located within the LSA although some sources are located within the broader regional context (e.g., mining and settlements). For the purposes of this assessment, the LSA is expected to have a clean air quality with minimal pollutants.

Air emission may occur from Project components and activities that could affect the environmental setting for First Nations cultural practices in the LSA. With the exception of summer seismic exploration, Project activities will occur mostly during the winter months when soils are frozen. As a result, fugitive dust produced by the Project is anticipated to be minimal and to only occur during the summer.

Air emissions may occur from Project activities that involve the combustion of fossil fuels (exhaust) during seismic exploration, drilling, and reclamation and closure activities. Air emissions in the LSA from sources such as light-duty trucks, ATVs and snowmobiles, heavy equipment, as well as stationary sources such as the drilling rig, and camp equipment are expected to be localized to areas where equipment is being operated.

Based on previous air quality assessments for the Project area, air quality effects from the mobile and stationary sources is anticipated to be minor and localized in areas of active road construction, well site, and camp operations (Yukon Environmental and Socio-economic Assessment Board 2020).

11.3.2.5.2 Noise

The existing acoustic environment within the LSA is characterized by a generally low level of ambient noise. Anthropogenic noise sources within the LSA include vehicle traffic along the Dempster Highway, operations at the Chance Camp and may include occasional ATV or skidoo engines or overhead air traffic.

While Project-related activities may result in an evident increase in noise levels, perception will be dependent on the receptors locations relative to the noise source as the level of sound decreases with distance from the source. As a result, the perception of most sources of Project-related noise are anticipated to be limited to the area in proximity to Project activity. Yukon First Nation Citizens and Gwich'in Participants engaged in cultural practices along the Dempster Highway may be near sources of noise from the surface infrastructure at the CPF or activity at the MBC sites. There are existing noise sources at these locations related to operations at the Chance Camp and traffic along the Dempster Highway and, consequently, it is anticipated that the incremental increase in noise from the Project would not be easily discernible from the existing ambient noise level in these portions of the LSA.

Yukon First Nation Citizens and Gwich'in Participants engaged in cultural practices within the remote areas of the LSA may be near sources of noise from Project exploration activity and well sites. Considering the small amount of Yukon First Nation Citizens and Gwich'in Participants cultural use that was identified as occurring in the LSA, the overall exposure to increased noise from the Project is expected to be limited and infrequent. There is, however, the potential for Yukon First Nation Citizens and Gwich'in Participants exposure to increased noise from the Project to be more prominent at particular cultural use areas within the LSA where they may be in closer proximity to Project exploration activity and well sites. As a result, the incremental increase in noise from Project components and activities is expected to be discernible to Yukon First Nation Citizens and Gwich'in Participants within the existing ambient noise level of the LSA as the Project progresses.

11.3.2.5.3 Visual Disturbance

The predominately natural landscape setting of the LSA is composed of a large expanse of mostly flat to rolling sub-arctic terrain covered by generally sparse forests and scattered wetlands. Built features include the gravel surfaces of the Dempster Highway and resource roads, as well as a network of seismic cut lines throughout the forested landcover.

Visual disturbance from exploration and drilling activities will occur progressively throughout the Project footprint in relation to clearing for new access roads and seismic exploration, the introduction of built features (e.g., wellsite surface infrastructure), and related safety and security lighting. It is anticipated that temporary visual disturbances will occur related to the presence of equipment and materials at the Chance Camp site during the early construction period, and the presence of Project vehicles for vegetation clearing, drilling, and well maintenance activities along Project access roads during exploration activities.

The movement of aircraft and helicopters during the summer seismic program, would be temporary and may attract the attention of Yukon First Nation Citizens and Gwich'in Participants on the land. Lighting of the surface infrastructure at the CPF, well sites (and related to flaring events) and from Project vehicles (e.g., mulchers, LIS drills, light-duty trucks) will be most visible during the winter and periods of low light and is likely to attract the attention of Yukon First Nation Citizens and Gwich'in Participants on the land within an otherwise naturally dark nighttime environment.

It is anticipated that visual disturbances from Project structures and vegetation clearing that will occur along the Dempster Highway (i.e., near the Chance Camp and MBC site) will be partially screened from view by Yukon First Nation Citizens and Gwich'in Participants engaged in cultural use activities. Visual disturbances related to seismic exploration and well sites in more remote portions of the LSA may blend into the existing visual landscape when viewed from a distance but have the potential to be more evident to Yukon First Nation Citizens and Gwich'in Participants within close proximity while engaged in cultural use activities. Based on the small amount of Yukon First Nation Citizens and Gwich'in Participants cultural use that was identified as occurring in the LSA, the overall potential for viewing of Project activities is expected to be limited. Considering the overall scale and form of the visual disturbance that would result from the Project, and the expected limited viewing opportunities, the Project is not anticipated to be a prominent feature within the LSA and is expected to result in a minor disturbance to potential viewing opportunities related to Yukon First Nation Citizens and Gwich'in Participants cultural use in the LSA.

The minor increases in air emission, noise level and visual disturbance are expected to be perceivable and have the potential to affect the environmental conditions valued by Yukon First Nation Citizens and Gwich'in Participants as setting for cultural activities within some portions of the LSA. However, these incremental effects are not expected to change the overall experience of Yukon First Nation Citizens and Gwich'in Participants engaging in cultural activities from the existing conditions. As a result, the effects on environmental conditions are not anticipated to affect the cultural identity of Yukon First Nation Citizens and Gwich'in Participants or their ability to continue the transmission of Traditional Knowledge with the LSA.

Concern about potential perceived adverse effects on the environmental surroundings of the LSA may occur with First Nations despite the application of mitigation measures. First Nations values related to cultural identity and cultural activities such as the transmission of the Traditional Knowledge are often interconnected with a broader community health and wellness. An effect, actual or perceived, on one value may result in effects on other cultural values. Effects to health and wellbeing are assessed in **Section 11.4 Community Health and Wellbeing.**

11.3.3 Mitigation Measures

The Project design includes management measures to avoid or reduce anticipated effects that have been identified through ongoing engagement, applicable standards, guidelines, and Best Management Practices (BMPs). These include the components listing in **Table 11-11** relevant to addressing Project-related effects on land and resource use.

Table 11-11. Mitigation Measures Relevant to Land and Resource Use and the Eagle Plains Exploration Project

Mitigation and Management Measure	Potential Effect Addressed by Mitigation
Application of constraints analysis and mapping	To minimize effects to high-value wildlife habitat, wetlands, and riparian areas.
Use of existing disturbances, burn areas, and natural open areas.	To minimize the spatial extent of new cutting for winter roads and seismic line preparation where possible.
Implementation of BMP to minimize air emissions, noise, and visual disturbance.	To minimize air emissions, noise, and visual disturbance.

Mitigation and Management Measure	Potential Effect Addressed by Mitigation
Use of doglegs in seismic lines.	Reduce the visual effect of straight linear features visible from the Dempster Highway.
Disturbed areas will be subject to the measures in a Reclamation and Closure Plan.	Allows for progressive decommissioning and reclamation of areas when they are no longer necessary for the Project.
Other VESEC-specific mitigation measures related to wildlife, fish, and vegetation as outlined in **Sections 6, 7, 8 and 9**.	Address effects related to wildlife, fish, and vegetation.

No further mitigation measures are identified to address potential effects on land and resource use.

11.3.4 Effects Characterization

11.3.4.1 Approach

The assessment approach used to characterize the predicted adverse residual effects on land and resource use follows the methodology outlined in **Section 11.1.4 Methods: Effects Assessment.** The residual effect characterization is based on criteria specific to Socio-economic VESECs, as presented in **Section 11.1.4.3 Methods: Characterization of Residual Effects.**

11.3.4.2 Residual Effect

Residual effects on the Land and Resource Use VESEC are expected, including a change in the environmental conditions for recreational use, a change in land area and access for First Nations cultural use, and a change in environmental conditions for First Nations cultural use. The Project's environmental and/or socio-economic context and potential limitations of data and uncertainty associated with the assessment are also considered in determining adverse residual effects. Residual effects and related context and confidence are characterized in **Table 11-12** to **Table 11-17** below.

These residual effects on environmental conditions for recreational use are characterized in **Table 11-12**.

Table 11-12. Characterization of Residual Effects on Environmental Conditions for Recreational Use

Criterion	Rating	Rationale
Magnitude	Low	The Project-related changes to environmental conditions for recreational use as a result of minor increases in air emission, noise level and visual disturbance are expected to be perceivable by recreational users but are not expected to change the overall experience compared to existing conditions.
Likelihood	Probable	The Project-related changes to environmental conditions for recreational use are likely to occur as a result of minor increases in air emission, noise level and visual disturbance
Geographic Extent	Local	The Project-related changes to environmental conditions for recreational use are predicted to be localized to small portions of the LSA

Criterion		Rating	Rationale
Duration, Frequency, and Timing	Duration	Medium-Term	The Project-related changes to environmental conditions for recreational use are predicted to occur progressively during the Project-lifecycle (i.e., 10-years)
	Frequency	Periodic	The Project-related changes to environmental conditions for recreational use is related to periods when recreational activities overlap with Project activities
	Timing	Year-round	The Project-related changes to environmental conditions for recreational use have the potential to occur throughout the year
Reversibility		Reversible	The Project-related change to environmental conditions for recreational use are predicted to decrease or stop with closure and reclamation of the Project.

11.3.4.3 Context and Confidence

The ratings and rationale for the assessment of residual effects on environmental conditions for First Nations cultural use are described in **Table 11-13.**

Table 11-13. Context and Confidence of Residual Effects on Environmental Conditions for Recreational Use

Criterion	Rating	Rationale
Context	Moderate	• Environmental conditions have been identified in regional land use plans as being valued for supporting recreation and tourism. • Concerns have been expressed related to Project-related effects on air quality, noise, visual effects, and light (including along the Dempster Highway) through engagement with local communities and First Nations.
Confidence	Moderate	• Information about recreational use within the LSA was limited. This was addressed through interviews with key informants (including representatives from First Nations and local communities). • Technical assessments were not available to quantify the environmental conditions or measure Project effects on air quality, noise, and visual disturbance. This was addressed with qualitative characterizations of the existing environmental setting and anticipated interactions with Project components. • Management measures identified in the Project design will be partially effective at addressing effects (e.g., established BMPs).

These residual effects on land area and access for First Nations cultural use are characterized in **Table 11-14**.

Table 11-14. Characterization of Residual Effects on Land Area and Access for First Nations Cultural Use

Criterion		Rating	Rationale
Magnitude		Low	Project-related disturbance footprint and access restrictions have the potential to decrease the availability of lands and disrupt access for First Nations cultural uses that will represent a minor change from existing conditions but is considered consistent within the existing pattern of available land and access.
Likelihood		Possible	A Project-related change to the availability of lands and disruption of access may occur dependent on First Nations cultural use of the Project footprint.
Geographic Extent		Local	Project-related change to the availability of lands and disruption of access for First Nations cultural uses are predicted to be localized to portions of the LSA.
Duration, Frequency, and Timing	Duration	Medium-Term	Project-related change to the availability of lands and disruption of access for First Nations cultural use are predicted to occur progressively throughout the life of the Project (i.e., 10-years).
	Frequency	Periodic	Project-related change to the availability of lands and disruption of access is related to periods when First Nations cultural use overlaps with Project activities.
	Timing	Year-round	Project-related change to the availability of lands and disruption of access for First Nations cultural uses have the potential to occur throughout the year.
Reversibility		Reversible	The Project-related change to the availability of lands and disruption of access for First Nations cultural uses are predicted to decrease or stop with closure and reclamation of the Project.

11.3.4.4 Context and Confidence

The ratings and rationale for the assessment of residual effects on land area and access for First Nations cultural use are described in **Table 11-15.**

Table 11-15. Context and Confidence of Residual Effects on Land Area and Access for First Nations Cultural Use

Criterion	Rating	Rationale
Context	Moderate	• Yukon First Nation Citizens and Gwich'in Participants have constitutionally protected rights and interests related to cultural activities on Traditional Territories and established land settlement agreements. • The ability of First Nations to conduct cultural practices based on customs, beliefs, and values, is dependent, in part, on access to areas of their Traditional Territories for cultural use. • Concerns have been expressed related to Project-related effects on land and resource use through engagement with local communities and First Nations.

Criterion	Rating	Rationale
Confidence	Moderate	• Information about Yukon First Nation Citizens and Gwich'in Participants cultural use areas and access to the LSA was limited. This was addressed with the review of secondary Traditional Knowledge sources and interviews with key informants (including representatives from First Nations and local communities). • Management measures identified in the Project design will be partially effective at addressing effects (e.g., established BMPs).

These residual effects on environmental conditions for First Nations cultural use are characterized in **Table 11-16**.

Table 11-16. Characterization of Residual Effects on Environmental Conditions for First Nations Cultural Use

Criterion		Rating	Rationale
Magnitude		Low	The Project-related changes to environmental conditions for First Nations cultural use are expected to be perceivable by Yukon First Nation Citizens and Gwich'in Participants but are not expected to affect their cultural identity or ability to continue the transmission of Traditional Knowledge compared to existing conditions.
Likelihood		Probable	The Project-related change to environmental conditions for First Nations cultural use are likely to occur as a result of increases in air emission, noise level and visual disturbance.
Geographic Extent		Local	The Project-related change to environmental conditions for First Nations cultural use are predicted to be localized to portions of the LSA.
Duration, Frequency and Timing	Duration	Medium-Term	The Project-related change to environmental conditions for First Nations cultural use are predicted to occur progressively throughout the life of the Project (i.e., 10-years).
	Frequency	Periodic	The Project-related change to environmental conditions is related to periods when First Nations cultural use overlaps with Project activities.
	Timing	Year-round	The Project-related change to environmental conditions for First Nations cultural use has the potential to occur throughout the year.
Reversibility		Reversible	The Project-related change to environmental conditions for First Nations cultural use are predicted to decrease or stop with closure and reclamation of the Project.

11.3.4.5 Context and Confidence

The ratings and rationale for the assessment of residual effects on environmental conditions for First Nations cultural use are described in **Table 11-17.**

Table 11-17. Context and Confidence of Residual Effects on Environmental Conditions for First Nations Cultural Use

Criterion	Rating	Rationale
Context	Moderate	• Yukon First Nation Citizens and Gwich'in Participants have constitutionally protected rights and interests related to cultural activities on Traditional Territories and established land settlement agreements. • Environment conditions have been identified as being valued for the way they support cultural uses and identity. • Concerns have been expressed related to Project-related effects on air quality, noise, visual effects, and light through engagement with local communities and First Nations.
Confidence	Moderate	• Information about Yukon First Nation Citizens and Gwich'in Participants cultural use in the LSA was limited. This was addressed with the review of secondary Traditional Knowledge sources and interviews with key informants (including representatives from First Nations and local communities). • Technical assessments were not available to quantify the environmental conditions or measure Project effects on air quality, noise, and visual disturbance. This was addressed with qualitative characterizations of existing environmental setting and anticipated interactions with Project components. • Management measures identified in the Project design will be partially effective at addressing effects (e.g., established BMPs).

11.3.5 Significance

The determination of significance of the predicted residual effects on land and resource use is based on definitions presented in **Section 11.1.4.3 Methods: Characterization of Residual Effects.** Magnitude, geographic extent, and duration are the primary factors affecting the significance determination. The significance of all residuals effects is assessed in combination to determine the overall affect of the Project on land and resource use after mitigations are applied.

The predicted Project-related changes to the environmental conditions are expected to be perceivable by recreational users but are not expected to change the overall experience on the land compared to existing conditions. The Project-related disturbance footprint and access restrictions have the potential to decrease the availability of lands and temporarily disrupt access for First Nations cultural uses as the Project progresses.

The predicted Project-related changes to the environmental conditions are expected to be perceivable by Yukon First Nation Citizens and Gwich'in Participants but are not expected to affect their cultural identity or ability to continue the transfer of Traditional Knowledge compared to existing conditions. The collective residual effects on land and resource use represent a minor change from existing conditions. Residual effects are predicted to be localized and occur over the 10-year life of the Project. With the implementation

of management measures (e.g., regulatory requirements and established BMPs), the collective residual effects of the Project on land and resource use are anticipated to be **not significant**.

11.3.6 Follow-up Monitoring

To address the uncertainty of potential interactions of the Project, follow-up monitoring is required to identify unanticipated social effects and to respond adaptively through coordination with First Nations, residents of local communities, and the YESAB Executive Committee or relevant regulators (if required). Chance will organize and implement coordination of follow-up monitoring to support identification and response to potential community and economic effects of the Project. This coordination will involve the review of results from Chance's proposed follow-up monitoring programs as well as feedback from First Nations and local communities to provide direction on the adaptive implementation of Project design, mitigation and benefit enhancement measures related to potential socio-economic effects.

11.3.7 Cumulative Effects Assessment

11.3.7.1 Approach

The assessment of cumulative effects on the Land and Resource Use VESEC follows the methods outlined in **Section 3.1.6 Cumulative Effects** and **Section 11.1.4.6 Cumulative Effects.**

Three residual Project effects were identified for land and resource use that could act cumulatively with other past, present or reasonably foreseeable projects and activities: (1) Residual Effects for Change in Environmental Conditions for Recreational Cultural Use (2) Residual Effects for Change in Land Area and Access for First Nations Cultural Use, and (3) Residual Effects for Change in Environmental Conditions for First Nations Cultural Use. For the purposes of the CEA, effects for changes in environmental conditions for Recreational Use and for First Nations Cultural Use were combined because both are attributable to a common set of sensory factors (i.e., air quality, noise, visual disturbance). The land and resource use CEA considers potential residual effects of the Project on the changes to environmental conditions, and changes to area use and access for cultural use that may interact spatially and temporally with past, present and reasonably foreseeable projects and activities listed in **Table 3.8** in **Section 3.1.6.4 Cumulative Effects Analysis.**

11.3.7.2 Cumulative Effects

The land and resource use CEA identified ongoing projects and reasonably foreseeable projects that may occur within the land and resource use RSA defined in **Table 11-1** in **Section 11.1 Methods**. This area consists of Game Management Subzones overlapping the Project footprint and provides a regional context for the assessment of Project-related effects to area use and access, wildlife resources that may support land and resource use, and environmental conditions. Other ongoing projects and reasonably foreseeable projects that may contribute to changes to environmental conditions, and changes to area use and access for cultural use within the RSA are presented in **Table 11-18**. These include the removal and disposal of hazardous waste at the Eagle Plains Solid Waste Disposal, the construction and maintenance of the Old Crow winter and all-season road, and the development of lands for mineral, gravel, and/or oil and gas resources within the region.

Table 11-18. Past, Present, and Reasonably Foreseeable Projects and Activities with Potential to Act Cumulatively with Project Effects on Land and Resource Use

Project Name or Activity	Spatial / Temporal Overlap	Project or Activity Contributions
Eagle Plains Solid Waste Disposal (ongoing)	• Within the RSA (approximately 15 km from Project) • Overlaps with 10-year life of Project (to occur over the 25 years, starting in 2024)	• Change in environmental conditions related to the potential for increased air emissions and noise.
Old Crow Winter (ongoing) and All-Season Road	• Within the RSA (traversing from Eagle Plains to Old Crow adjacent to the Project footprint) • Overlaps with 10-year life of Project (control access opened in 2022 and is ongoing)	• Increased access for First Nations to cultural use areas.
Mineral Exploration	• Potentially located within the RSA (location not known) • May overlap with 10-year life of Project	• Change in environmental conditions related to the potential for increased air emissions, noise, and visual disturbance. • Reduction in the availability of lands from the exploration area footprint and disruption to access for First Nations cultural uses.
Gravel quarries- Unnamed	• Potentially located within the RSA (location not known) • May overlap with 10-year life of Project	• Change in environmental conditions related to the potential for increased air emissions, noise, and visual disturbance. • Reduction in the availability of lands from the quarry footprint.
Oil and Gas	• Potentially located within RSA (location not known) • May overlap with 10-year life of Project	• Change in environmental conditions related to the potential for increased air emissions, noise, and visual disturbance. • Reduction in the availability of lands from oil and gas exploration or development area footprint and disruption to access for First Nations cultural uses.

The Eagle Plains Solid Waste Disposal project activity is likely to overlap only during the first few years of the Project (to be completed prior to 2026) if scheduled operations occur as planned. It is predicted to result in some increased air emissions related to the exhaust from heavy equipment and project vehicles, as well as fugitive dust from closure activities such as removal of remaining stockpiles, backfilling, and topping (particularly during dry summer conditions). Noise related to closure activities is anticipated from heavy equipment and closure activities. Changes to environmental conditions are predicted to be localized to small portions of the LSA and temporary. Post-closure monitoring is not expected to create a change to existing conditions.

The Old Crow winter road was opened to restricted traffic in 2022 to facilitate the movement of materials into the community of Old Crow and support future infrastructure projects (Government of Yukon 2022). The road is anticipated to be open seasonally depending on the weather with the intent of further

development into an all-season road. The Vuntut Gwitchin Government will control access and the road has the potential to increase accessibility for Vuntut Gwitchin First Nations Citizens to remote areas within the LSA for cultural uses more easily.

Existing placer and quartz claims are located outside the RSA and it is unlikely that development of lands for mineral exploration will occur within the region. The NYRLUP and PWRLUP identify the highest potential for industrial development of the RSA to be in relation to oil and gas production. Current oil and gas exploration in the RSA is related to oil and gas claims held by Chance Oil and Gas Ltd. (which are the focus of this Project Proposal). Several dispositions for gravel pits occur within the RSA along the Dempster Highway. As a result, there is the potential for the development of future gravel quarries that may result in a change to environmental conditions from increased air emissions (e.g., dust), noise, and visual disturbance, as well as a reduction in the availability of lands that may be related to First Nations cultural uses along the Dempster Highway.

A characterization of cumulative effects for land and resource use is provided in **Table 11-19** below**.**

Table 11-19. Characterization of Cumulative Effects on Land and Resource Use

Criterion		Rating	Rationale
Magnitude		Low	Ongoing projects and reasonably foreseeable projects that may occur within the region have the potential to act cumulatively with Project-related residual effects resulting in minor changes to environmental conditions (i.e., increases in air emissions, noise, and visual disturbance), and/or minor changes to the access to or area available for First Nations cultural uses from existing conditions.
Likelihood		Certain to Possible	The likelihood that cumulative effects will occur is certain for ongoing projects, but dependent on the development of other reasonably foreseeable projects.
Geographic Extent		Local	Cumulative effects are expected to be localized to the Dempster Highway and adjacent to the Project footprint.
Duration, Frequency and Timing	Duration	Short-term to Medium-term	Cumulative effects are expected to occur throughout the life of the Project (i.e., 10 years) with some of the other projects and activities scheduled to overlap only the first few years of the Project.
	Frequency	Periodic	Cumulative effects are expected to generally occur in relation to seasonal operating periods (i.e., summer or winter).
	Timing	Seasonal	Cumulative effects are expected to occur seasonally.
Reversibility		Reversible	The cumulative effect will decrease or stop with closure and reclamation of the Project and/or other projects and activities.

Potential climate change effects could cumulatively interact with residual Project effects on land and resource use resulting in changes to the overall environmental setting of the landscape for recreational and cultural use, and changes to the area and access for Yukon First Nation Citizens and Gwich'in Participants cultural use over the 10-year life of the Project. Climate change effects such as flooding, erosion, and wildfires may reshape landforms and the pattern of vegetation resulting in changes to the structure and overall character of the landscape setting within the RSA. Climate change effects such as erosion and

wildfires may also affect the air quality from an increased dust or airborne particulate matter from wildfires. Access to, and areas of Yukon First Nation Citizens and Gwich'in Participants Traditional Territories for cultural use within the RSA may be disturbed or altered by climate change effects such as flooding, erosion, and permafrost thaw.

11.3.7.3 Context and Confidence

The Project's environmental and/or socio-economic context and potential limitations of data and uncertainty associated with the assessment were considered for the assessment of cumulative effects. The ratings and rationale for the context and confidence in accurately quantifying and predicting cumulative effects are described in **Table 11-20** below.

Table 11-20. Characterization of Context and Confidence in the Assessment of Cumulative Effects on Land and Resource Use

Criterion	Rating	Rationale
Context	Moderate	• Yukon First Nation Citizens and Gwich'in Participants have constitutionally protected rights and interests related to cultural activities on Traditional Territories and established land settlement agreements. • Information about recreational use and First Nations cultural use within the RSA was limited. This was addressed through review of secondary Traditional Knowledge sources and interviews with key informants (including representatives from First Nations and local communities). • Concerns have been expressed related to Project-related effects on land and resource use through engagement with local communities and First Nations.
Confidence	Moderate	• There is some uncertainty related to the ongoing or reasonably foreseeable project and activities. • Management measures identified in the Project design will be partially effective at addressing effects (e.g., established BMPs).

11.4 COMMUNITY HEALTH AND WELLBEING

This section provides an analysis of potential Project-related interactions with the Community Health and Wellbeing Valued Environmental and Socio-economic Component (VESEC). The assessment of Community Health and Wellbeing includes the following:

- potential Project-related changes to Environmental Quality that may affect human health (including changes to air quality, noise, drinking water quality, soil and sediment quality, and traditional foods quality); and,
- potential changes to Social Determinants of Health (including access to healthcare services, incidence of infectious and chronic disease, personal and relational safety, and Indigenous and cultural health).

This section focuses on potential Project-related effects to Community Health and Wellbeing for potentially affected First Nations and communities as identified in **Section 1.1**.

11.4.1 Assessment Indicators and Parameters

Community Health and Wellbeing was selected as a VESEC because of the potential for the Project to interact with health and wellbeing conditions of potentially affected First Nations and communities in the LSA. Spatial boundaries used for the assessment of Community Health and Wellbeing are listed in **Table 11-1**. Engagement activities with affected communities have also identified concerns associated with community health and wellbeing. These concerns include drilling locations and the potential to contaminate air and water and reduced trapping and hunting opportunities, as the Project footprint overlaps with traditional subsistence areas. **Section 2 Consultation and Engagement** describes the results of the Project Engagement Program with potentially affected First Nations and communities.

The communities in the LSA and RSA (**Table 11-1**) are the main communities and administrative centres for Yukon First Nation Citizens and Gwich'in Participants (Gwich'in peoples that are represented by the Gwich'in Tribal Council) potentially affected by the Project. However, some First Nations Citizens may not reside within these RSA communities. For example, approximately 200 Vuntut Gwitchin Citizens reside in Old Crow, though most Citizens reside in Whitehorse (refer to **Appendix 11-A** for further information relating to key informant interview data). In addition, non-Indigenous community members also reside in LSA and RSA communities. Yukon First Nation Citizens and Gwich'in Participants using the land around the Project for traditional activities may not be residents of the RSA communities. For this reason, this section refers to "First Nations and communities" to encompass all those who may be potentially affected by the Project.

The assessment indicators and parameters selected for the assessment of potential Project effects on the Community Health and Wellbeing VESEC are provided in **Table 3-2** in **Section 3 Methods.**

The assessment of human health effects associated with Project-related changes to environmental quality was informed by a desktop report on potential interactions between the Project and existing environmental conditions for air quality and noise, and by the results of biophysical VESECs (**Section 4** to **Section 9** of the Project Proposal). Methods used for this report are included in **Section 11.1**.

The assessment of community health effects was informed by the results of Project engagement, existing socio-economic conditions as described in the **Appendix 11-A** and the results of other socio-economic VESECs (**Section 11.2, 11.3,** and **11.5** of the Project Proposal).

11.4.2 Project Interactions and Potential Effects

Interactions may occur between Project-related activities and Community Health and Wellbeing during exploration, which is expected to include concurrent construction, operation, and maintenance activities. Potential interactions between Project activities and all VESECs are provided in **Table 3-5** in **Section 3 Methods.**

The Project is expected to interact with Community Health and Wellbeing. Most Project activities are anticipated to have a minor interaction. The assessment of potential interactions between Community Health and Wellbeing and selected Project activities is focused on assessing the interactions that may result in adverse effects. Project interactions and associated effects are described in this section. Interactions with Project components and activities expected to result in either no effects or a small effect that would result in no measurable change from existing conditions are described in **Section 11.1.4.1 Rationale for**

No or Negligible Interaction to provide a rationale for these findings. Interactions that are anticipated to result in a more substantial effect are described in **Section 11.4.1 Interactions**.

11.4.2.1 Rationale for No or Negligible Effects

Potential interactions that were evaluated as having no or negligible effect with the Project are described below and are not considered further in the assessment.

11.4.2.1.1 Negligible Effect on Human Health Associated with Changes to Drinking Water Quality

First Nations Citizens and other land users present in the LSA may drink from surface water sources while engaged in activities on the land. For example, key informant interview data confirms First Nations land users boil snow for use as drinking water during winter land use activities (see **Appendix 11-A** for further information). Key informant interview data also identifies that surface water is sampled to establish baseline conditions for creeks and rivers within Vuntut Gwitchin First Nation territory, with the Whitestone River being used as an important cultural area for harvesting trips. The extent of surface water use for drinking water by other First Nations and LSA or RSA community land users is unknown, particularly during spring, summer, and fall months. Information about whether this water is treated or boiled before consumption is also uncertain. Therefore, a conservative approach is required, and it is assumed that people in the LSA may be using surface water for drinking, which could affect human health if water sources contain COPCs.

Drilling activities have been noted as a concern by First Nations Citizens, noting they are concerned that fluid injections from drilling at well sites may change groundwater quality. These are acknowledged as key concerns by LSA and RSA communities, and as an important indicator of community perceptions and potential stressors to mental health. Gwich'in Tribal Council expressed concern about spills and the effect of fluid injection in geological formations on groundwater specifically. Gwich'in Tribal Council also requested that Chance outline the risk levels for each well to be explored, based on the type of fluid used for injection and the spill response plan to be shared with Gwich'in Tribal Council when a spill occurs. Gwich'in Tribal Council also identified concerns about the use of temporary and permanent Project roads affecting water quality and associated risks to fish within the LSA. First Nation of Na-Cho Nyäk Dun identified concerns about the potential for soil and surface water contamination resulting from the drilling project, with particular attention to the active injection wells and well maintenance activities. Vuntut Gwitchin First Nation and residents of Old Crow also expressed concerns around the impact of seismic activities and drilling locations (and related effects) to water quality, and that water was a key issue for them.

Current COPCs present in surface water within the LSA include aluminum, cadmium, copper, iron, and manganese in levels that exceed the Canadian Water Quality Guidelines for the Protection of Aquatic Life (see **Section 5 Water Resources** and **Section 6 Fish and Fish Habitat).** Isolated surface water quality that exceeds drinking water guidelines within the LSA include:

- arsenic from Chance and Dalglish creek sites;
- selenium from McParlon, Eagle and Dalglish creek sites; and,
- mercury, which was observed to be slightly elevated in a single sample at a single site (Environmental Dynamics Inc. 2023a; Moher 2023).

These exceedances occurred at specific sites for specific chemical parameters (**Section 5 Water Resources**) (Moher 2023). The source of these elevated COPCs is unknown, though naturally occurring metals are known to be present in regional soils (Moher 2023).

Project components that could negatively affect the quality of surface water used for drinking include increased sedimentation from erosion (e.g., removal of riparian trees to accommodate temporary stream crossings, use of mobile equipment), and contaminant or nutrient influxes indirectly from increased metal concentrations (due to increased runoff). Project activities that may increase sedimentation from erosion may enhance soil erosion on waterbodies that could exacerbate the previously high level of COPCs in LSA water bodies that would impact drinking water quality for land users. The potential effects to surface water identified that some residual effects to surface water (including increased sedimentation, and contaminant or nutrient influxes) will be negligible after mitigations (**refer to Section 5 Water Resources for further discussion).**

The health risk associated with ingestion of drinking water is only present if land users within the LSA are regularly ingesting contaminated surface water (Moher 2023). There is the potential for surface water to be used as drinking water within the RSA, including Glacier Creek, Rock River, and Sheep Creek, located roughly 120 kilometres north of the LSA. These creeks all drain from the Richardson Mountain that flows into Peel or Eagle River System. While key informant interviews have confirmed that snow is boiled and used as drinking water for winter land-based activities in the LSA, it is uncertain how or if surface water is used by First Nations or recreational land users for drinking during spring, summer, or fall land use activities (e.g. harvesting, hunting, or trapping), or whether this surface water is treated prior to ingestion (refer to **Appendix 11-A** for further information). Concerns from First Nations Citizens around changes to surface and groundwater may also lead to the reduction or abandonment of land use activities within the LSA or RSA due to health and safety concerns around drinking water sources for land users. While there is limited information around land users ingestion of surface water as drinking water during spring, summer, and fall months, mitigation measures for surface water are expected to maintain negligible changes to surface water quality. The mitigation measures identified in **Section 5 Water Resources** minimize the likelihood of changes to drinking water quality, which is assessed as negligible but acknowledging the uncertainties around land user behaviour.

11.4.2.1.2 Negligible Changes to Health Associated with Changes to Air Quality

Project emissions from the use of equipment in the Project footprint (as described in **Table 3-3**) will present some local and transitory effects to air quality which could be detectable by First Nation Citizens and other land users in close proximity to the Project footprint. First Nations Citizens may be engaged in activities on the land in the LSA, such as harvesting and subsistence activities, cultural activities, and travel to traditional use areas. Ambient air quality in the LSA is assumed to be generally good as the Project is located in a remote area with limited human activity. Air quality may be adversely affected by wildfire smoke during the summer wildfire season.

Air emissions may contain contaminants of potential concern (COPC), which could be inhaled by land users (Moher 2023). COPCs for this assessment refer to any contaminant that has the potential to cause risk or adverse effects to humans related to their release in air, water, soil, or country foods (Health Canada 2017; Moher 2023). Anticipated or potential emissions from the Project are expected to include carbon dioxide emissions from fossil fuel combustion, small quantities of sulphur dioxide (if unanticipated hydrogen

sulphide is present in natural gas) during flaring activities, methane (fugitive emission in oil and gas activities), and to a lesser extent, nitrous oxide emissions may also occur (see **Section 1 Details of the Proposed Project**).

Localized Project-related changes in air quality could also occur related to flaring activities and combustion of fossil fuels primarily during the winter months (see **Section 1 Details of the Proposed Project**). There may be some minor dust generation from Project activities in the summer months, relating to seismic recording and helicopter use, though these will be intermittent and localized occurrences.

Hydrogen sulphide is not expected to be present in the reservoir based on data obtained historically by Chance and during drilling activities conducted by Chance between June 2012 and June 2013. Therefore, hydrogen sulphide from the reservoir or exposure to sulphur dioxide from flaring is not expected. The risk of greenhouse gas exposure to land users (from flaring) within the LSA is considered to be very low, due to quick dissipation into the ambient air (Moher 2023; Yukon Environmental and Socio-economic Assessment Board 2020). Based on data obtained during drilling operations and historic data, there does not appear to be naturally occurring H_2S, and exposure risks to H_2S and greenhouse gases for land users are not anticipated.

Fossil fuel combustion may affect air quality during seismic exploration and drilling activities where equipment is being operated (such as trucks, service vehicles or ATVs operating around a well site or a seismic line) (**Section 11.3 Land and Resource Use**). Combustion of fossil fuels to transport and operate equipment will be relatively low and localized in areas of active road construction or within well site vicinities (Yukon Environmental and Socio-economic Assessment Board 2020). First Nations citizens who are intermittently using areas of the LSA during their hunting or trapping periods may be able to detect localized and transitory changes to air quality due to the Project.

Some airborne particulates in the form of dust are commonly produced by vehicles driving on unpaved roads and erosion of sediment or soil from areas cleared of vegetation. The Project is not expected to produce large quantities of airborne particulates as it has been scheduled during the winter months when soils are frozen and access to well sites can be accomplished through winter roads. Most of the summer harvesting activities for First Nations would occur adjacent to the Dempster Highway, where vehicle use may release some dust particulates from the road (**refer to Section 11.1 Community Infrastructre and Services** for further information about traffic assessments relating to dust). Helicopter use in the summer months relating to seismic exploration and recording may cause increased dust in localized areas during take-off or landing in areas where the site has been cleared, those these are anticipated to be local and intermittent occurrences. There is a suitable amount of moisture in the soil during summer months that would also limit land user inhalation of dust in the LSA. Refer to **Section 11.2 Land and Resource Use** for further information on air quality.

Overall, human health risks associated with changes to air quality from Project activities are expected to be infrequent and intermittent for First Nations and recreational land users in the LSA. Based on current information, this potential effect is considered to be negligible and is not further assessed.

11.4.2.1.3 Negligible Changes to Health Associated with Changes to Traditional Food Quality

Traditional foods include plants, wildlife, fish, and other resources in the LSA that may be harvested by First Nations Citizens for consumption. For the purposes of this assessment, the Community Health and Wellbeing VESEC addresses Project interactions that may change the quality of traditional resources used as foods. Project components may adversely affect the quality of resources in the Project footprint and LSA through potential pathways such as air emissions (including dust), or release of potential COPCs to surface water and soils (due to surface runoff during freshet and rainfall events which may transport emissions and dust to water bodies). Changes to human health associated with changes to the quality of traditional foods may occur through the ingestion of plants and berries, fish, or wildlife. Key informants (including representatives from First Nations and local communities) shared through the socio-economic interview program (see **Section 11.1 Methods and Appendix 11-A**) was used to address concerns and current traditional food practices. No mapping information was available for the assessment.

11.4.2.1.3.1 Traditional Plant and Berry Harvesting

Traditional plant and berries harvested by First Nations citizens may be affected by increased fugitive dust associated with Project activities. Fugitive dust from the Project may be inhaled directly by people engaged in land-based activities, or dust may settle on vegetation in areas of the LSA used for traditional plant and berry harvesting and may be consumed. Key informant interviews identified berry and medicinal plant harvesting in the LSA, including gathering areas around the southeast corner of the proposed Project Footprint, near Dalglish Creek, Enterprise Creek, and the Dempster Highway. Traditional plants and berries harvested in these areas include blueberries, salmonberries, and cranberries. Primary interview data also indicated that a small number of First Nations land users harvest plants and berries around the Dempster Highway during the summer months).

Exposure to contaminants from fugitive dust may occur from construction activities, seismic recording, or increased transportation on access roads and around the Dempster Highway. Fugitive dust from Project activities could be inhaled by people present in the LSA, with inhalation associated with increased respiratory irritation that could have a detrimental effect to human health.

The potential for dust inhalation is expected to be limited to summer months from Dempster Highway traffic. Airborne particulates in the form of fugitive dust are anticipated to result primarily from helicopter takeoffs and landings, the use of vehicles on roads in the summer under dry conditions, during clearing or mulching of woody vegetation for seismic line preparations, excavation of the MBC sump area, and wind erosion on exposed soil.

Apart from seismic operations (including seismic exploration and recording), the majority of Project activities are scheduled for the winter months (such as the drilling exploration activities, EFT flaring, and seismic line construction) when soils are frozen and site access can be accomplished via winter roads. Any dust from seismic recording or increased transportation on the Dempster Highway that may increase dust on traditional plants and berries is anticipated to be limited, due to the high moisture content of the soils within the LSA during the summer. Therefore, fugitive dust produced by the Project is anticipated to be minimal, and the potential effects to human health associated with changing quality of plants and berries is anticipated to be negligible.

11.4.2.1.3.2 Fish Food Quality

Fish harvested during the summer months could potentially be affected by the Project, due to the potential for surface water quality changes, such as increased sedimentation from erosion (e.g., removal of riparian trees to accommodate temporary stream crossings, use of mobile equipment), and contaminant or nutrient influxes indirectly from increased metal concentrations (due to increased runoff). (see **Section 5 Water Resources** and **Section 6 Fish and Fish Habitat** for further discussion).

Key informant interview data informed that fish consumption has declined in the area due to the depletion of salmon stocks in waterbodies, with ice fishing occurring intermittently for burbot. Engagement with First Nations identified concerns around the perception of water quality and subsequent potential impacts to fish: First Nation of Na-Cho Nyäk Dun identified concerns about the potential for soil and surface water contamination resulting from the drilling project, with particular attention to the active injection wells and well maintenance activities. Vuntut Gwitchin First Nation and residents of Old Crow also expressed concerns around the impact of seismic activities and drilling locations (and related effects) to water quality, and that water is an important issue.

As described in **Section 6 Fish and Fish Habitat**, existing conditions indicate that the LSA provides a summer habitat for fish, though no salmon species were detected during summer or winter fish surveys. During the winter, most waterways were frozen to the bed, dewatered, or had dissolved oxygen levels that could not sustain fish. While most Project activities will be conducted during the winter (i.e., EFT flaring, drilling exploration, well injections, access trail and seismic line construction), it is understood that seismic recording will occur during the summer months. Best practices were considered for bore well design and operation practices in order to support environmental protection measures from contamination.

While perceived impact to fish quality may impact the quantity of fish caught in the summer by First Nation land users, primary interview data indicates that there has not been a high volume of land users fishing in the area due to existing declines in salmon and other fish species in nearby waterways. Therefore, changes to health associated with changes to fish food quality is anticipated to be negligible.

11.4.2.1.3.3 Game Foods (Wildlife) Quality

Project components could result in increased COPCs in surface water or soils. Based on current information, Project-related activities are not expected to result in elevated tissue concentrations of COPCs in wildlife within the LSA. Wildlife may also be affected by Project-related changes to sensory conditions (such as noise, vibration, and light), which could result in changes to wildlife movements and avoidance of affected areas.

Yukon First Nations land users may hunt and trap game animals in the LSA (Moher 2023). Key informant interview data noted that marten, lynx, wolves, moose, and caribou are hunted and/or trapped within traditional territories that overlap with the proposed Project Footprint. Trapping in the Eagle Plains area by Yukon First Nations largely occurs around the Dempster Highway, and usually in the winter season for marten, lynx, and wolf furs. Caribou and moose hunting occurs by Yukon First Nation land users in the spring and fall in the area around Old Crow. Hunting, trapping, and harvesting of wildlife is an important key for cultural continuity which informs health and wellbeing for Yukon First Nations.

Further information and detail relating to key informant interview summaries can be found in **Appendix 11-A**. The majority of hunting and trapping activities are understood to occur around the Dempster Highway

during the winter months and around Old Crow during the spring and summer months. There is no direct contaminant exposure for wildlife from Project activities that would expose Yukon First Nation land users to contaminants through the ingestion of wildlife. Based on current information, this potential effect is negligible and is not further considered in the assessment.

11.4.2.1.4 Negligible Effects to Access to Healthcare Services

Increased demand from Project employees and staff on healthcare services in LSA and RSA communities could put additional pressure on healthcare services in LSA and RSA communities. The additional demand could in turn contribute to reduced access and/or longer waiting times for LSA community members, which could negatively affect health outcomes for some individuals if.

The communities in the Social Determinants of Health LSA and RSA include Whitehorse, Old Crow, Fort McPherson (NWT), Dawson City, and Village of Mayo. These communities have a variety of healthcare services and community services related to long-term healthcare (such as nursing and residential care facilities), social services, and addiction services. Key informant interview data identified that current healthcare staff in LSA and RSA communities tailor educational programs and workshops to the community's needs. Services are scheduled to accommodate and target specific sub-groups within community populations in an attempt to reduce current healthcare access barriers.

The Project workforce will be small (roughly 75–80 staff), with direct employment opportunities varying based on Project components. The highest demand for project labour will be during Exploration (specifically during the winter drilling and EFT activities). Project employees will have access to a full-time nurse practitioner on site at the main Chance Camp (see **Section 1 Details of the Proposed Project**). Project medical emergency plans include identification of nearest hospital, alternative hospital locations, and transportation protocols (e.g., use of medivac where needed, airlift to Whitehorse) (see **Section 1 Details of the Proposed Project**). It is not anticipated that Project workers or their families will relocate to LSA or RSA communities or create a measurable demand on existing healthcare services. Given the small workforce for the Project, it is unlikely that there would be additional pressures placed on accessing regular healthcare services in the LSA and RSA. Access to healthcare services is assessed as negligible and is not carried forward for further assessment.

11.4.2.1.5 Negligible Effects to Infectious Disease Rates

Transmission of infectious diseases is an important consideration in camps where many people are working in close quarters. This issue is also important to communities in the LSA and RSA if workers visit or live in LSA and RSA communities. The Chance Camp is located on the Dempster Highway at km 324, and is anticipated to have a small labour force, with some employees residing at the Eagle Plains hotel for short periods of time that may encounter hotel employees or other temporary hotel residents. Given the remote location of the Chance Camp, it is not anticipated that employees would be at high risk of spreading any camp-wide infectious disease outbreaks into the LSA or RSA communities. As a result of this analysis, the potential interaction of the Project with infectious diseases is not carried forward for further assessment.

11.4.2.2 Interactions

Project components and activities interactions with Community Health and Wellbeing were evaluated following the approach in **Section 3.1.4.1 Project Interactions and Potential Effects.** Three potential effects are expected for Community Health and Wellbeing:

- A potential adverse effect on human health associated with personal and relational safety; and,
- a potential adverse effect on human health associated with changes to First Nations cultural practices.

The pathways for the potential adverse effects are described in the following section.

11.4.2.3 Potential Effects

11.4.2.3.1 Potential Adverse Effects to Health Associated with Personal and Relational Safety

Personal safety refers to the conditions necessary to prevent harm and worry around changes to physical and emotional safety, such as through hostility, aggression, and harassment (Vector Research, Hanson and Associates, and Jen Jones Consulting 2022). Relational safety considers Indigenous perspectives and knowledge of safety and focuses on the broader relationships between an individual and their community, the land, and ecology (Vector Research, Hanson and Associates, and Jen Jones Consulting 2022). This includes how a person's identity can expose them to different forms of discrimination, violence, or harassment, and other harms that affect relationships to land, family, and community.

This subsection assesses personal and relational safety subcomponents related to the Project. The Project may affect personal and relational safety in LSA and RSA communities through increased availability of substances (including alcohol and illegal drugs), which may contribute to increased substance use and crime in LSA and RSA communities. Key informant interview data are used to support this assessment, for further details please refer to **Appendix 11-A.**

11.4.2.3.1.1 Substance Use

Employment related to the Project may increase the average income of people living in the RSA, including local First Nations employees hired for Project activities, or indirectly through increased economic opportunities for local businesses (refer to **Section 11.5 Employment and Economy** for further detail). Although increased income is rightly viewed as a positive economic effect, increased income may also adversely affect community health and wellbeing through contributing to increased substance use. Some Project workers may also increase their substance use because of having increased income during off-rotation periods. There is no anticipated increase in the availability of alcohol in communities within the RSA relating directly to the Project, although larger incomes from Project employment opportunities may make alcohol and substances more affordable to workers and their families. The increase in incomes may also increase demand for recreational and illegal drugs, which would fuel an increased local supply and availability for residents.

Substance use (including use of alcohol and drugs) is closely related to both individual physical and mental health and personal and relational safety, including increased incidences of crime. The data available on substance use and consumption can be an indicator for the prevalence of substance use-related incidences

within the LSA and RSA. In Yukon overall as of 2015, adults aged 25 and over made an average of over 1,000 visits to the Emergency Department annually for problems directly associated with drug and or alcohol use (Government of Yukon 2015). While Old Crow is a dry community (alcohol is prohibited), there is currently a community emergency declaration for Old Crow by Vuntut Gwitchin First Nation to recognize the substance use crisis faced by residents of Old Crow and the broader Vuntut Gwitchin community due to increased drug poisoning from alcohol and opioids (MacIntyre 2023).

The Government of the Yukon declared a substance use health emergency in January 2022 in response to the ongoing effects of contaminated illicit drug supplies across the territory (Government of Yukon 2022b). Support centres for mental wellness and substance use services are available at the Dawson City Health Centre in Dawson City, as well as in Whitehorse for withdrawal management services, counselling, and intensive treatment programs (Government of Yukon 2022b). Key informant data interviews indicated that the COVID-19 pandemic exacerbated feelings of isolation and stress, which likely led to a spike in substance use in remote Yukon communities.

Although Chance cannot be responsible for any employee's actions while not at work, the company can promote a reduction of substance use harm among its employees and the employees of any Project contractors to help ensure a safe worksite, reduce employee turnover, and help to protect the general health and wellbeing of its employees and their communities. The Project will run a substance-free workplace to enhance safety, with substance testing required by individual employees. However, potential adverse effects on health could occur if employees increase their alcohol use during the weeks they spend at home. Additional measures to reduce risks related to increased alcohol and substance use may include support through the provision of information about health and wellness education resources available to employees and their families, and access to counselling services made available through worker benefits.

The Project labour force is anticipated to be small (approximately 75-80 persons at the main camp), and moderate precautions are taken within the assessment to reflect the context of the RSA, where there are higher levels of vulnerable community members and an ongoing, territory-wide state of emergency in Yukon for drug poisoning). Based on the analysis summarized above, the potential effect on community health and wellbeing related to increased substance use is carried forward for further assessment.

Mitigation measures, such as the implementation and enforcement of Project employment and anti-discrimination policies, and cultural awareness and sensitivity training) have been identified for minimizing (and wherever possible) avoiding increases in violence and crime. Mitigation actions and policies will help increase the positive outcomes of the Project and reduce the adverse risks of increased income (such as drug and alcohol consumption, and the effects of stress from work rotations on individuals, families, and local communities). Steady employment and increased incomes are associated with better individual and family health, and improved family stability. Once construction and exploration activities are completed, there will be a reduction in the workforce. Thus, potential effects are predicted, with increased income offering both positive and negative effects to LSA and RSA communities. This is carried forward for further assessment.

11.4.2.3.1.2 Crime

There is potential for increased crime and subsequent demand on policing services from LSA communities (as described in **Section 11.3 Community Services and Infrastructure**), which would be associated with increased presence of transient workers from the Project in LSA communities. Key informant interview data

identified that within RSA communities there are generally few instances of crime, largely made up of thefts and public disturbances (refer to **Appendix 11-A** for further information). Key informant interview data also indicated that RSA communities generally share similar crime patterns to other small and remote northern communities, with the isolation and lack of winter employment anecdotally linked to restlessness and crime increases during the winter months.

An adverse effect on community wellbeing may occur based on alcohol and drug-related crimes resulting from an influx of transient workers recreationally visiting RSA communities during off-shift rotations. Chance will transport employees from the LSA and RSA communities directly to their home and back to the work site. Employees hired from outside the local northern region will also be transported to and from site and home base, while passing through Dawson or Whitehorse. It is anticipated that there will be limited or no interaction in local communities from Chance employees during these transitions. In addition, limited number of workers (approximately 25) will be located at any given time at smaller fly-in camps at remote well sites, roughly 40 kilometres from the Chance Camp. It is currently unknown whether workers will be in communities during any phase of Project activities, or whether they would be visiting RSA or LSA communities during their 10 day off-rotation shifts.

Police services in LSA communities are provided by the Royal Canadian Mounted Police (RCMP) detachments within each RSA community. RCMP detachments are present in Whitehorse, Old Crow, Fort McPherson, and Dawson City. The RCMP also provides policing services to the community of Mayo and surrounding area, although limited information is available for this detachment (Royal Canadian Mounted Police 2023).

11.4.2.3.1.3 Summary

While the Project has a small work force in a remote area, there remains uncertainty as to whether local residents will be employed by the Project (see **Section 11.5 Employment and Economy**), and uncertainty on whether and to what extent non-local (out of region) employees will be visiting LSA and RSA communities. The Project could increase substance use rates within LSA and RSA communities, which may subsequently increase crime rates, as seen in seasonal patterns of petty crime incidents noted through key informant interview data.

Substance use increases in RSA communities are currently high and precautions are taken within the assessment to address the uncertainty of actual substance use rates for local and transient employees. The potential for substance use to increase in LSA and RSA communities as a result of the Project may contribute to a change in personal and relational safety for LSA and RSA communities, and this effect is carried forward for further assessment.

11.4.2.3.2 Potential Adverse Health and Wellbeing Effects Associated with Changes to First Nations Cultural Practices

Connection with the land, culture, and tradition are essential foundations for diverse First Nation wellness (Council of Yukon First Nations 2015). Project components that could negatively affect the ability of Yukon First Nations Citizens to engage in cultural practices may therefore have an indirect effect on community health and wellbeing. For example, Project components such as seismic recording, drilling, and transport of materials, workers and equipment will create noise and visual changes. These sensory disturbances may result in altered wildlife behaviour, that may subsequently reduce traditional food quantity or access.

Engagement activities identified concerns around changes to land that may negatively affect spiritual and cultural uses and relationships to the land, thereby negatively affect mental health of First Nations Citizens (see **Section 2 Consultation and Engagement** for further detail). Vuntut Gwitchin First Nation and residents of Old Crow identified concerns about changes to the land in relation to potential Project effects to permafrost, air and water quality, seismic activities, drilling locations, and overall effects on the Porcupine Caribou Herd. Similarly, Gwich'in Tribal Council identified concerns around climate change from Project-related activities that may change the land and wildlife that Gwich'in Participants depend on for food, land use, and travel for traditional purposes. Tr'ondëk Hwëch'in First Nation identified concerns related to permafrost and the Porcupine Caribou Herd from Project-related effects, noting that the herd not only has high value as a source of traditional food, but that the herd is important for cultural and spiritual wellbeing.

Ongoing engagement with LSA and RSA communities identified how First Nations teachings around traditional food may extend beyond subsistence activities to include cultural values, teachings, and perspectives around identities and community responsibilities. The Project may disrupt the protection, persistence, and living of Yukon First Nations indirectly either through physical changes to the environment, reduced resources used (including traditional food resources), or effects on the experience of being on the land and water in ways that inform Yukon First Nations' health. Yukon First Nation Citizens in the RSA may be discouraged from harvesting plants for traditional foods or medicines, or hunting and trapping, due to perceptions around reduced availability of vegetation and wildlife, access restrictions related to safety from the winter access trails, or increased noise affecting the experience. Key informant interview data and ongoing engagement with Yukon First Nations have identified concerns relating to the potential reduction in hunting for fur-bearing animals (particularly moose and caribou), as well as Project-related effects that may impact permafrost and Porcupine Caribou Herd migrations and behaviours. Refer to **Appendix 11-A** for further information from key informant interviews.

Perceived effects on the quality and quantity of traditional foods, including plants, berries, and culturally important wildlife species (such as the Porcupine Caribou Herd, moose, marten, lynx, and wolf) may adversely affect First Nation members participation in harvesting and subsistence activities, as well as cultural and spiritual practices relating to health and wellbeing. The real or perceived potential for the Project to adversely effect traditional foods may adversely affect the perceived value of traditional foods and could lead to a decline in harvesting activities in the LSA or RSA. This may have an indirect adverse effect on First Nation health and wellbeing based on culturally defined understandings of health.

First Nation Citizens that practice traditional activities within the LSA may come into closer proximity to Project-related sources of noise, but this would be minimal, infrequent, and intermittent in exposure. Due to the minimal nature of the potential exposure to noise to First Nation Citizens and recreational land users, the risk of effects to human health for First Nations and recreational land users from noise is predicted. It is possible that Project-related sources of noise could influence wildlife behaviours, leading to avoidance behaviours and a reduced wildlife presence at areas with noise, light disturbances, and other sensory effects (particularly for moose and caribou, which are culturally important species for RSA communities). Refer to **Section 9 Caribou** and **Section 10 Wildlife and Wildlife Habitat** for further information on wildlife behaviour assessments.

The avoidance or reduced presence of traditional game species may alter how Yukon First Nation land users hunt and trap in the LSA across the exploration activities of the Project. It is unknown how this may impact quantity of traditional foods, though a low disturbance rate is anticipated. There are no anticipated

effects to hunting, trapping, or fishing, or the cultural activities practiced within sustenance harvesting areas as a result of Project-related noise (see **Section 11.3 Land and Resource Use**) (Government of Yukon 2021).

In addition to the potential effect to community health and wellbeing due to physical changes associated with the Project, Project employees that are locally sourced from LSA and RSA communities may experience reduced health associated with changes in their ability to practice traditional cultural activities due to the boundaries of employment. Stress relating to shift rotations for local First Nations employees and its associated lifestyle changes may lead to increased workplace stress and isolation, and a reduced feeling of health if cultural practices on the land are not able to be maintained. There is a potential adverse health effect of the Project on mental health and wellness in potentially affected communities, where effects related to stress on workers and their families can increase due to shift rotations and associated lifestyle changes. There is a potential adverse effect for First Nations and recreational land users' mental health and wellness, understanding that visual changes to their landscape and land use experience may impact their mental health and wellbeing.

Enhanced measures associated with current traditional Land and Resource Use (see **Section 11.3 Land and Resource Use**) may be used to support the local values and potential benefits that the Project can contribute to the potentially affected First Nations through all phases of the Project.

Based on current information, health and wellbeing changes associated with Project-related changes to Yukon First Nations cultural practices is predicted as a potential adverse effect.

11.4.3 Mitigation or Enhancement Measures

The Project design includes management measures to avoid or reduce anticipated effects that have been identified through ongoing engagement, applicable standards, guidelines, and Best Management Practices. These include components listed in **Table 11-21** relevant to addressing Project-related effects.

Table 11-21. Mitigation Measures Relevant to Community Health and Wellbeing and the Eagle Plains Exploration Project

Mitigation and Management Measure	Potential Effect Addressed by Mitigation
Continued use of the main Chance Camp and remote camps to accommodate employees	Minimizes needs for a commuting workforce and reduces changes to personal and relational safety for RSA and LSA communities.
Implementation of substance-free workplace to enhance safety, with substance testing required by individual employees	Reduces changes to personal and relational safety for RSA and LSA communities.
Transportation of local and southern Yukon employees directly from Chance Camp to their home and back to work site	Limit or reduce interactions in local communities from Chance employees during these transitions to reduce changes to personal and relational safety for LSA and RSA communities.
Implementation and enforcement Project anti-discrimination policies, harm reduction training, and cultural awareness safety training	Support employees experiencing difficulties with substance use or discrimination; supports local First Nation employees' traditional practices and cultural important time periods; reduce changes to personal and relational safety for local First Nations employees and RSA and LSA communities

Mitigation and Management Measure	Potential Effect Addressed by Mitigation
Providing space (if available) for people to quietly connect with online Alcoholics Anonymous or Narcotics Anonymous meetings where rooms are available	Support local First Nations employees experiencing difficulties with substance use; reduce changes to personal and relational safety for RSA and LSA communities.
Cultural awareness through cultural safety training and cultural awareness training for Project employees may be supportive through such practices as describing traditional land and resource uses, traditional territories, and other important cultural dimensions of local Yukon First Nations through the Introduction and Overview of the Project area during new employee orientation. The Project may also enhance employee understanding through supportive practices that allow for First Nations and other Indigenous employees to pursue traditional activities on the land (outside of Project area) during their off-shift work rotation schedules.	Supports local First Nation employees' traditional practices and cultural important time periods; reduce changes to health associated with reduced access to First Nations cultural practices and traditional food sources
Take measured approach under guidance of the NYRLUP to limit potential negative effects to ungulates from Project activities	To reduce altered behaviours and avoidance in game animals that would impact First Nation Citizens harvesting, hunting, and trapping in the LSA and RSA
Noise management plan to provide further direction on reductions in noise exposures for land users in the LSA	To reduce altered behaviours and avoidance in game animals that would impact First Nation Citizens harvesting, hunting, and trapping in the LSA and RSA
Reduction or limit to Project activities during key wildlife timing windows (i.e., rutting, or calving season)	Reduce impact on First Nation Citizens access to land and quantity of traditional food sources

11.4.4 Residual Effects Characterization

The assessment approach used to assess the characterization of potential adverse effects follows the methodology outlined in **Section 11.1.4.3 Characterization of Residual Effects**, based on the definitions for residual effects classification criteria specific to Socio-economic VESECs presented in **Section 11.1 Methods.**

Residual adverse effects to Community Health and Wellbeing VESEC include:

- residual adverse effects to community health associated with personal and relational safety; and,
- residual adverse effects to community health associated with changes to First Nations cultural practices.

11.4.4.1 Residual Adverse Effects to Personal and Relational Safety - Increased Substance Use

Despite mitigation measures aimed at supporting employees in reducing harm from substance use (inclusive of alcohol, opioids, and other illicit drugs), the Project may contribute to increased substance use in the LSA during construction and exploration activities, due to presence of non-residents in LSA and RSA communities and an increase in income for local employees and contractors in LSA communities (**Table 11-22**).

The residual effect is likely to be low to moderate in magnitude, assessed to acknowledge the increased vulnerability within the Yukon for a territory-wide emergency, and due to the age-adjusted rate (per 100,000 individuals) for drug poisoning in the Yukon being the highest in the country. The timing of the effect will likely reflect current substance use and drug poisoning rates. An increase in substance use indicators, including total number of emergency-department visits relating to alcohol or substance use, as well as any increases in drug poisoning deaths in the LSA may be used to monitor for any increases within the LSA.

Based on similar projects within the Yukon (Coffee Gold 2016) and the above characterization, the residual adverse effect is likely to result in **significant** residual effects for employees and community members in the LSA. The confidence in this assessment is moderate, as the proportion of employees and potentially affected LSA residents is unknown and due to uncertainty in the effectiveness of mitigation measures.

Table 11-22. Effects Characteristics Ratings and Significance Increased Substance Use (alcohol, opioids, and non-opioid drug use)

Residual Effects Characterization		Rating	Rationale
Magnitude		Low to moderate	Increased substance use rates in the north exceed Canadian averages, and the relative increase in substance use related to the Project is likely to be relatively low in magnitude, but moderate in the context of a vulnerable LSA and RSA population.
Likelihood		Likely	It is likely that there will be an increase in substance use related to an increase in incomes for employees and indirectly for LSA community members.
Geographic Extent		Social determinants of health LSA	Concern is focused on the Project workers and their families, with some connection to LSA communities that would indirectly have increased income from the Project's presence in the region.
Duration, Frequency and Timing	Duration	Short-term	Any incidents of increased substance use will likely be isolated.
	Frequency	Infrequent	Any incidents of increased substance use will likely be isolated and infrequent.
	Timing	Seasonal	Possible increase in seasonal fluctuations, though no data are available on peak times for alcohol or substance-use hospitalizations or poisoning available through Yukon Government.
Reversibility		Reversible	Any increase in substance use would likely be related to increase in income for employees and indirectly for LSA community members related to Project activities.
Context		Moderate	The number of employees (or total proportion of employees) and LSA community members that will be affected is unknown

Residual Effects Characterization	Rating	Rationale
Confidence	Low	Uncertainty in the effectiveness or implementation of mitigation measures.

11.4.4.2 Residual Adverse Effect to Human Health Associated with Changes Yukon First Nation Cultural Practices

Project-related effects to health associated with changes to Yukon First Nation cultural practices include any changes related to reduced access to the land or reduction in traditional food quantity. These may occur through Project activities that increase noise and sensory disturbances that may alter game animal behaviour and or reduce their presence in the LSA in ways that would limit or modify how Yukon First Nations land users are able to participate in cultural activities that are essential for health. Changes to health may also occur through mental health stressors relating to Project employment for local First Nations employees, such as increased stress or isolation that would interrupt their ability to practice important cultural activities. Project-related effects to health are expected to be negative, with a low to moderate likelihood of occurring, with uncertainties on total impact to quantity of wildlife in the LSA (**Table 11-23**).

Table 11-23. Effects Characteristics Ratings and Significance for Changes Health Relating to Changes to Yukon First Nation Cultural Practices

Residual Effects Characterization		**Rating**	Rationale
Magnitude		Low to moderate	Project-related activities that would affect health for Yukon First Nations land users that hunt and trap wildlife in the LSA or local First Nations employed by the Project is likely to represent a small proportion of land users accessing the LSA based on seasonal movements of wildlife.
Likelihood		Likely	The adverse residual effect may occur should exploration activities proceed. Stress from shift work structures and isolation is likely to occur for local First Nations employees due to the nature of shift work and fly-in remote camps.
Geographic Extent		Local to environmental determinants of health LSA	Concern is focused on areas where Yukon First Nations land users would typically hunt or trap wildlife for traditional food sources in the LSA, including the main Chance Camp where any local First Nations Project employees would reside.
Duration, Frequency and Timing	Duration	Short-term	If a residual effect were to occur, a reduction in traditional food quantity or access would be limited to periods where noise or sensory disturbances occur within Project exploration phase. Periods of mental stress would also be limited to phases of the Project that involve

Residual Effects Characterization		Rating	Rationale
			shift work that may impede ability to participate in cultural activities for health.
	Frequency	Periodic	Reduction in quantity of traditional foods or access may be limited to periodic phases of the Project that would include noise or sensory disturbances (i.e., seismic recording, EFT flaring, drilling activities, and well injection activities) and based on movement patterns of wildlife (e.g., for moose or caribou)
	Timing	Year-round	Project activities would occur seasonally, with majority of activities occurring through winter, that may affect year-round hunting and harvesting of traditional food.
Reversibility		Reversible	Effects of wildlife movements and behaviours are reversible; once Project activities stop, effects on traditional food quantity and access would be expected to cease.
Context		Moderate	Despite isolated nature of Project footprint, the area overlaps with traditional territories where Yukon First Nations have rights for traditional hunting and harvesting activities under the Umbrella Agreement.
Confidence		Moderate	Moderate confidence that wildlife movement effects will be limited to a small proportion of game animals that would affect traditional food quantity and access for land users. Moderate certainty about how wildlife in the annual work area may modify their local movements and consequences of those modifications for land users.

11.4.5 Significance

The determination of significance of the predicted residual effects on health associated with changes to drinking water quality, changes to personal and relational safety, and changes to Indigenous cultural practices are based on the definitions presented in **Section 11.1.4.3 Methods: Characterization of Residual Effects.** Magnitude, geographic extent, and duration are the primary factors affecting the significance determination.

The predicted Project-related impacts on First Nations and recreational land user health values are understood as both actual and perceived, understanding that varying opinions exist on whether the mitigation measures will be sufficient to ensure the lasting health of individuals, communities, land, water, and wildlife within Yukon First Nation Traditional Territories. Despite the proposed mitigation measures, community members may have remaining concerns about the damage that will extend beyond the physical environment, as land, water, and wildlife relationships are closely tied with the health and culture of the

people living within the LSA and RSA. Each of these community values are interconnected, and as a result, impacts to one value may have a ripple effect throughout each connected value. As an example, potential (actual or perceived) changes to surface water quality include contamination of drinking water that may have associated changes to human health from ingestion of contaminated sources. It may also impact traditional cultural practices or the ability to maintain relationships with fish, fishing areas, and riverbank vegetation that may be used for medicinal or traditional consumption.

The potential Project-related changes will occur throughout the life of the Project (i.e., 10 years), related to ongoing and periodic occupational exposures through seasonal Project activities, and regular movements of material, equipment, and workers to and from the Project footprint. After the implementation of mitigation measures, the Project is predicted to result in some **significant** residual adverse effects for RSA communities and First Nations land users (**Table 11-24**).

Table 11-24. Determination of Significance for Changes to Social Determinants of Health

Characterization	Definition
Significant	The low to moderate magnitude of adverse residual effects for RSA communities, including First Nations Citizens and other recreational users that hunt, trap, harvest, and access the land around the Project footprint during seasonal periods within the Social Determinants of Health LSA. Sensory disturbances from Project activities are most likely to occur during winter months, though Project design and Occupational Health and Safety measures will mitigate and reduce some risks (e.g., mental health and substance use for local First Nations employees).

11.4.5.1 Follow-Up Monitoring

To address the uncertainty of potential interactions of the Project (e.g., surface water quality for drinking purposes), follow-up monitoring is recommended to identify any unanticipated social effects and to respond adaptively through coordination with First Nations, residents of local communities, and the YESAB Executive Committee or relevant regulators (if required). Chance will organize and implement the coordination of follow-up monitoring to support identification and responses to potential community health and wellbeing effects of the Project. This coordination will involve the review of results from Chance's proposed follow-up monitoring programs, as well as feedback from First Nations and other local residents within RSA communities to provide direction on the adaptative implementation of Project design, mitigation, and benefit enhancement measures related to potential socio-economic effects.

Monitoring activities may include air, water, wildlife, or other monitoring activities as suggested by community engagement.

11.4.6 Cumulative Effects Assessment

11.4.6.1 Approach

The assessment of cumulative effects on the Community Health and Wellbeing VESEC follows the methods and criteria outlined in **Section 3.1.6 Cumulative Effects** and Section **11.1.4.6 Cumulative Effects.**

Three potential cumulative effects were identified for Community Health and Wellbeing:

- adverse residual effect to health associated with personal and relational safety; and,

- adverse residual effect to health associated with changes to Yukon First Nations cultural practices.

For the purposes of the Cumulative Effects Assessment (CEA), the discussion of cumulative effects to health associated with changes to drinking water quality and changes to Yukon First Nations cultural practices were combined, as both are attributable to a common set of sensory factors (i.e., air quality, noise, visual disturbance, water quality, traditional food quantity). The Community Health and Wellbeing CEA considers the potential residual effects of the Project on the changes to environmental conditions, and changes to use and access of the area for Yukon First Nations cultural practices that may interact spatially and temporally with past, present, and reasonably foreseeable projects and activities listed in **Table 3.8** in **Section 3.1.6.4 Cumulative Effects Analysis.**

While there is the potential for broader interactions between RSA communities and Project employment that may affect health associated with personal and relational safety, it is difficult to assess the cumulative effects for this from the list of projects provided and are not considered within the CEA.

11.4.6.2 Cumulative Effects

The Community Health and Wellbeing CEA identified ongoing projects and other reasonably foreseeable projects that may occur within the community health and wellbeing RSA defined in **Table 11-1** in **Section 11.1 Methods.** This area consists of the Game Management Subzones overlapping the Project footprint and provides a regional context for the assessment of Project-related effects to area use and access for Yukon First Nation cultural practices, including wildlife and water resources that may support access and quantity of traditional food for Yukon First Nation health. Other ongoing projects and other reasonably foreseeable projects that may contribute to changes to environmental conditions, and changes to area use and access for health associated with Yukon First Nation cultural practices within the RSA are presented in **Table 11-25** below. These include the removal and disposal of hazardous waste at the Eagle Plains Solid Waste Disposal, the construction and maintenance of the Old Crow winter and all-season road, and the development of lands for mineral, gravel, and/or oil and gas resources within the region.

Table 11-25. Past, Present, and Reasonably Foreseeable Projects and Activities Identified for Cumulative Effects on Community Health and Wellbeing

Project Name or Activity	Spatial / Temporal Overlap	Project or Activity Interaction with VESEC
Dempster Highway Granular Pit Development: km 188, 208, and 232 (proposed)	• Within RSA (within 93 to 137 km from Project) • Overlaps with 10-year life of Project (project activity will occur every 2-3 years until 2046)	• Effects on soil and vegetation; adverse environmental effects on caribou that could contribute to traditional food quantity loss or reduced access to land associated with health for Yukon First Nations
Sheep Creek Gravel Pit: km 433 Dempster Highway (ongoing)	• Within RSA (within 108 km from Project) • May overlap early period of Project (project activity will occur every 2-3 years until 2031)	• Contaminants may be introduced in small amounts and remain in the environment over several years; contributions to changes in traditional food quality associated with health

Project Name or Activity	Spatial / Temporal Overlap	Project or Activity Interaction with VESEC
Ogilvie Grader Station Solar, km 195 Dempster Highway (ongoing)	• Within RSA (within 130 km from Project) • May overlap early period of Project (construction to start from 2023-2028 and last 4 month. Lifespan of project is 25 years)	• Heritage resource loss, alteration, or destruction has the potential to act cumulatively with the potential changes to health associated with changes to Yukon First Nations cultural practices (include access to land and traditional food quantity)
Granular Pit Exploration + Development – km 158 (ongoing)	• Within RSA (167 km from Project) • Overlaps with 10-year life of Project (activity will occur every 3-5 years)	• Heritage resource loss, alteration, or destruction has the potential to act cumulatively with the potential changes to health associated with changes to Yukon First Nations cultural practices (include access to land and traditional food quantity) • Adverse effects on wildlife may act cumulatively with changes to health associated with traditional food quality or quantity
Old Crow Winter (ongoing) and All-Season Road	• Within RSA (traversing from Eagle Plains to Old Crow adjacent to the Project footprint) • Overlaps with the 10-year life of the Project (control access open in 2022 and is ongoing)	• Increased access for Yukon First Nation Citizens to traditional food harvesting, hunting, and trapping areas (potential to increase access and quantity of traditional foods)
Mineral Exploration - general	• Within RSA (potentially accessed along the Dempster Highway) • May overlaps with 10-year life of Project	• Adverse effects on wildlife may act cumulatively with changes to health associated with traditional food quality or quantity
Gravel quarries-Unnamed	• Within RSA (potentially accessed along the Dempster Highway) • May overlaps with 10-year life of Project	• Adverse effects on wildlife may act cumulatively with changes to health associated with traditional food quality or quantity
Oil and Gas – general	• Within RSA (potentially accessed along the Dempster Highway) • May overlaps with 10-year life of Project	• Adverse effects on wildlife may act cumulatively with changes to health associated with traditional food quality or quantity

Specific projects in the RSA with activities may overlap with the Project are detailed as follows:

- Several land use permits for gravel pits occur within the RSA along the Dempster Highway. Quarry pit project activities (including Dempster Highway Granular Pit Development, Sheep Creek Gravel Pit, and Granular Pit Exploration + Development) are likely to overlap with the Project if scheduled operations occur as planned. Quarry activities are predicted to result in some effects to soil and vegetation, as well as to important game animals such as caribou using explosives once every 3 to 5 years and vegetation clearage. Changes to environmental conditions for vegetation and wildlife is anticipated to be localized to small areas of the RSA, will be mostly seasonal (occurring in summer to early fall), and temporary or reversible. Post-

closure monitoring is not expected to create a change to existing conditions. The development of future gravel quarries may result in a change to environmental conditions from increased air emissions (e.g., dust), noise, and visual disturbance, that may reduce the traditional food quantity or access for First Nations Citizens or reduce the availability of lands that may impact health associated with First Nation cultural practices within the RSA.

- The Eagle Plains Solid Waste Disposal project is likely to overlap only the first few years of the Project (to be completed prior to 2026) if scheduled operations occur as planned. The project is predicted to result in some contamination of water and aquatic resources related to the release of leachate into the natural environment. Changes to environmental conditions will be localized to small portions of the LSA and temporary. Post-closure monitoring is not expected to create a change to existing conditions.
- The Old Crow winter road was opened to restricted traffic in 2022 to facilitate the movement of materials into the community of Old Crow and support future infrastructure projects (Whitehorse Star 2022). The road is anticipated to be open seasonally depending on the weather with the intent of further development into an all-season road. The Vuntut Gwitchin Government will control access and the road has the potential to increase accessibility for Vuntut Gwitchin First Nations Citizens to access remote areas within the LSA for cultural practices associated with health and wellbeing more easily.
- Existing placer and quartz claims are located outside the RSA. It is unlikely that the development of lands for mineral exploration will occur within the region. The **NYRLUP** and **PWRLUP** identify the high potential for industrial development of the RSA in relation to oil and gas production. Oil and gas exploration in the RSA is related to oil and gas claims held by Chance Oil and Gas Ltd. (the focus of this Project Proposal).

A characterization of cumulative effects for land and resource use is provided in **Table 11-26** below**.**

Table 11-26. Characterization of Cumulative Effects on Community Health and Wellbeing

Criterion	Rating	Rationale
Magnitude	Low	Ongoing projects and other reasonably foreseeable projects that may occur within the region have the potential to act cumulatively with Project-related residual effects resulting in minor changes to environmental conditions (i.e., increases in noise, and visual disturbance affecting traditional food sources, contamination of surface water sources), and/or minor changes to the access or quantity of traditional foods important for First Nation cultural practices associated with health and wellbeing. It is expected that cumulative effects will represent a minor change from existing conditions.
Likelihood	Certain to Possible	The likelihood that cumulative effects will occur is certain for ongoing projects, but dependent on the development of other reasonably foreseeable projects.
Geographic Extent	Local	Cumulative effects are expected to be localized to the Dempster Highway and adjacent to the Project footprint.

Criterion		Rating	Rationale
Duration, Frequency and Timing	Duration	Short-term to Medium-term	Cumulative effects are expected to occur throughout the life of the Project (i.e., 10 years) with some of the other projects and activities scheduled to overlap only the first few years of the Project.
	Frequency	Periodic	The cumulative effects from other projects and activities are expected to generally occur in relation to seasonal operating periods (i.e., summer or winter).
	Timing	Seasonal	The cumulative effects of other projects and activities are expected to occur seasonally.
Reversibility		Reversible	The cumulative effect will decrease or stop with closure and reclamation of the Project and/or other projects and activities.

Potential climate change effects could cumulatively interact with residual Project effects to community health and wellbeing resulting in changes to the overall natural environment and landscape for First Nations cultural practices related to traditional food hunting, harvesting, and trapping over the 10-year life of the Project. Climate change effects such as flooding, erosion, and wildfires may reshape landforms and the pattern of vegetation resulting in changes to the structure and overall character of the landscape setting within the RSA. Climate change effects such as erosion and wildfires may also affect the air quality from an increased dust or airborne particulate matter from wildfires. Community health and wellbeing associated with First Nations cultural practices may be affected by changes in the access or quantity of traditional food hunting, harvesting, and trapping areas within the RSA that are disturbed or altered by climate change effects. These may include effects such as warming temperatures, as flooding, erosion, and permafrost thaw.

11.5 EMPLOYMENT AND ECONOMY

11.5.1 Assessment Indicators and Assessment Parameters

Potential effects of the Project on employment and economy were assessed using the methods described in Section 11.1 Methods. In addition, desk-based research was conducted to gather information on the existing socio-economic conditions. The research included a review of publicly available information and secondary using official sources such as Statistics Canada, Yukon Bureau of Statistics, NWT Bureau of Statistics, First Nations websites, and community websites (see **Appendix 11-A**).The assessment indicators and parameters selected for the assessment of potential Project effects on the Employment and Economy VESEC are presented in **Table 3.2** in **Section 3 Methods**.

11.5.2 Project Interactions and Potential Effects

The assessment approach for identifying Project interactions and potential effects was a systematic review of each of the listed Project components or activities within the context of existing conditions of the LSA for each of the indicators and assessment parameters of the Employment and Economy VESEC. As indicated in **Table 3-4** in **Section 3 Methods**, potential interactions of Project components and activities are expected to result in beneficial effects to existing conditions. The potential beneficial effects associated with these

interactions and the rationale for these determinations are described in this section to provide a rationale for these findings.

Potential interactions between Project components and activities and the Employment and Regional Economy VESEC are anticipated to have the following beneficial effects:

- positive effects on local and regional employment opportunities;
- positive effects on local and regional business opportunities;
- positive effect on economic diversity; and,
- no effect on territorial and local government finances.

11.5.2.1 Demand for Local and Regional Labour

Project-related effects on local and regional employment opportunities are expected to be positive. The Project is anticipated to be conducted over a ten-year period, with all the Project components and activities (e.g., infrastructure/well development, drilling, testing, reclamation) occurring somewhat concurrently. During this period, the Project will require a small workforce of up to 70 jobs. Direct employment opportunities resulting from Project components will vary depending on the activity (e.g., seismic exploration operations, exploratory drilling and EFT testing, and associated reclamation and closure). It is anticipated that the highest demand for labour will occur during the Exploration Phase (winter), specifically during the drilling and EFT activities.

Through the Project Engagement Program described in **Section 2 Consultation and Engagement**, concerns were expressed related to the ability for First Nations Citizens and residents of potentially affected communities to access employment opportunities created by the Project. Some of these concerns are related to the lack of qualified workers and training opportunities in the LSA and RSA. Additional concerns were raised about receiving information related to the Project's employment opportunities and requirements in a timely manner (see **Section 2 Consultation and Engagement**).

Project demands for labour, goods, and services have the potential to create job opportunities for communities located within the LSA, including Old Crow, Mayo, Dawson, and Fort McPherson, as well as other communities within the RSA such as Whitehorse and other Yukon communities. Economic effects on employment opportunities in the local and regional economies can be divided into three categories:

- Direct effects: related to positions directly required by Chance for each Project component.
- Indirect effects: related to employment opportunities arising from the purchase of goods and services for the Project, and labour for the production of these goods and services.
- Induced effects: associated with consumers and households spending wages and income earned from direct and indirect employment generated by the Project.
- Detailed information on the anticipated Project demands for direct labour for the duration of the Project are presented in **Table *11-27***.

Table 11-27. Estimated Employment Requirement for the Project

Project Component	Role	Direct Employment Estimates
Seismic Program	Line preparation supervisor	2 jobs
	Equipment operators	2 to 4 jobs
	Survey coordinator	2 jobs
	Surveyor	2 jobs
	Source preparation supervisor	2 jobs
	Equipment helpers	2 jobs
	Cruisers	2 jobs
	Slashers	2 jobs
	Packers	2 jobs
	Water truck driver	2 jobs
	Line crew	2 to 4 jobs
	Wildlife monitor	2 jobs
	Heritage monitor	2 jobs
	Road/Trail Construction and Maintenance	2 to 4 jobs
Drilling Program	Wellsite supervisor	2 jobs
	Service rig	2 to 4 jobs
	Security	2 jobs
	Wireline crew	2 jobs
	Slickline crew	2 jobs
	Truck drivers/operators (e.g., water tank, vacuum truck, picker/bed truck, fuel truck)	2 to 4 jobs
	Flow test crews	2 to 4 jobs
	Tool hand	2 jobs
	Cementing crew	2 jobs
	Wildlife monitor	2 jobs
	Heritage monitor	2 jobs
General Camp Operations	Nurse practitioner/medic	2 jobs
	Camp cooks	2 jobs
	Office staff	2 jobs
	Camp attendants	2 to 4 jobs
	Maintenance and cleaning staff	2 to 4 jobs
Total		**60 to 70 jobs**

Notes:

[1]Employment estimates were developed for the purpose of this assessment based on the Details of the Proposed Project (See **Section 1**) and information provided by Chance from previous projects with similar characteristics.

[2] Actual Project employment requirements may vary depending on the outcomes of the exploration activities.

The Project workforce will likely be comprised of a range of occupations, including trades, engineering and technical, heavy equipment operators, management, administrative and support roles. Filling employment opportunities resulting from Project demands for labour has the potential to increase employment within the communities located in the LSA and RSA.

Based on a review of other projects with similar characteristics (i.e., comparable scale and scope), the Project anticipates that between 15% to 30% of the Project labour requirements will be sourced from the communities located within the LSA. Between 15% to 30% of the Project labour requirements will be sourced from the broader Yukon, and 40% to 70% from beyond the RSA (e.g., AB, BC, and NWT). Entry-level and trades positions are likely to be available to individuals located within the LSA and RSA. Direct and indirect employment opportunities (e.g., contractors) are anticipated for activities such as:

- camp operations;
- logistics for freight and crew;
- equipment operation support;
- fuel supply;
- water and waste hauling;
- environmental and archaeological monitoring;
- winter roads, airfield, and well pad construction and maintenance; and,
- drilling and seismic programs.

The ability of people to benefit from Project-related employment opportunities is related to their ability to meet the employment requirements of the contractors who will perform Project-related components and activities, as well as their level of education and training. Actual Project employment requirements may vary depending on the outcomes of the Project's exploration activities.

In some cases, Project demands for labour may exceed the number of individuals in the communities in the LSA and RSA available for work and/or with experience in occupations related to the Project labour requirements. The benefits of increased Project-related employment will be more pronounced in communities where Project labour demand exceeds or absorbs the majority of qualified individuals, such as Old Crow, Fort McPherson, and Mayo. Given the size of the labour force in occupations related to the Project employment requirements in the LSA and RSA, it is anticipated that a large proportion of Project employment requirements can be addressed from within the LSA and RSA (up to 60%) and the rest from beyond the RSA (up to 50%).

Table *11-28* provides the number of individuals working or with experience in occupations related to the Project's labour requirements in communities located within the LSA and RSA.

Table 11-28. Labour Force Employed in Occupations Related to the Project Labour Requirements

Community	Labour Force in occupations related to Project employment requirements
RSA	
Yukon	8,965 persons
Whitehorse	6,190 persons
LSA	
Old Crow	55 persons
Fort McPherson (NWT)	100 persons
Dawson	350 persons
Mayo	50 persons

Notes:
[1] Labour Force in occupations related to Project employment requirements includes individuals working on senior management occupations, natural and applied sciences and related occupations, health occupations, trades, transport and equipment operators and related occupations, natural resources production occupations, and occupations in manufacturing and utilities.
Source: (Government of Canada 2022)

Individuals in other occupations and industries will likely seek employment opportunities in Project-related occupations to meet the increased demand. This may result in an indirect positive effect on the local and regional labour market due to an increase of skilled workers in these occupations. Overall, effects related to increased employment opportunities within the LSA and RSA resulting from the Project's demand for labour are anticipated to be positive.

Other resource extraction and development projects in the Yukon with similar types of labour requirements may compete with the Project for labour and services. The Project may also benefit from workers who have been employed by mines that are anticipated to be in temporary or full closure at the start of proposed Project activities. In 2023, there were eight major mining projects in the Yukon at various stages of development, ranging from proposed developments going through the YESAB review process to active mines and those in closure or post-closure phases (**Table 11-29**). Global commodity prices are a key factor in determining if projects come out of temporary closure or begin production.

Table 11-29. Major Mining Projects in the Yukon Territory (2023)

Project	Proponent/Owner	Approximate Location in Relation to the Project's Main Camp	Stage
Brewery Creek	Golden Predator Exploration Ltd.	310 km (south)	Project Proposal Application
Carmacks Copper	Granite Creek Copper	650–800 km (south)	Project Proposal Application
Casino	Casino Mining Corporation	800 km (south)	Project Proposal Application
Eagle Gold	Victoria Gold Production	600 km (east)	Production
Keno Hill Silver District	Hecla Mining Company	600 km (east)	Production

Project	Proponent/Owner	Approximate Location in Relation to the Project's Main Camp	Stage
Minto	Minto Metals Corporation	180 km (southeast)	Temporal Closure – For Sale
Sä Dena Hes	Sa Dena Hes Mine Operating Corporation	650 km (southeast)	Permanent Closure
Wolverine	Welichem Equipment Limited	180 km (east)	Temporal Closure

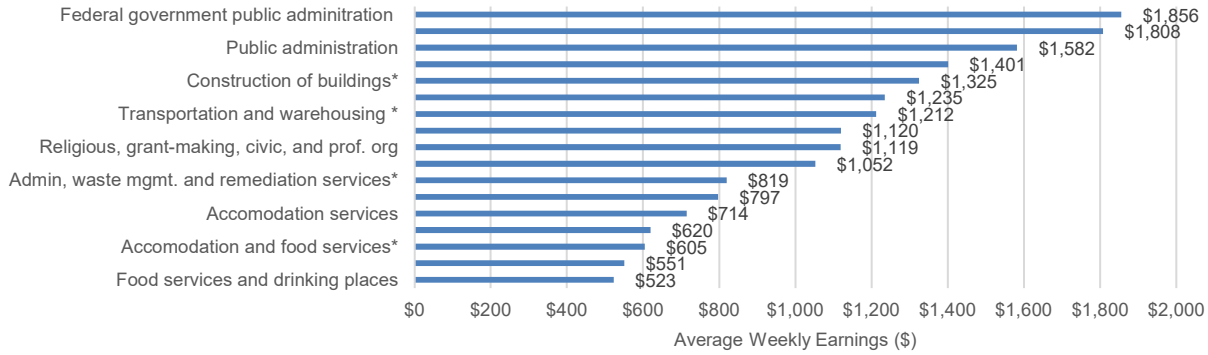
Source: (Government of Yukon 2023; Yukon Environmental and Socio-economic Assessment Board, n.d.)

In addition to direct employment opportunities, indirect benefits are anticipated for local and regional businesses that can supply goods and services to the Project. The purchase of goods and services for the Project can result in an increase in the economic activity of supplying companies, which could lead to additional indirect employment from Project-related activities.

Additional induced positive effects will likely result from the purchase of goods and services by those directly and indirectly employed by the Project. When wages and salaries are spent, the employment opportunities related to the businesses supplying these consumers with goods and services may increase (e.g., retail, hospitality, and other consumer sectors).

In addition, individuals within the LSA who may benefit from a direct Project-related employment opportunity are more likely to experience changes in their income levels than individuals working in other industries. Overall net effect on income distribution for individuals located within the LSA resulting from the Project's demands for labour are anticipated to be positive.

Information related to the average weekly earnings (including overtime) by selected industry sector and subsector for the Yukon in 2021, is presented in **Figure 11-1.**



Notes:
[1] Industry sectors, subsectors and industry groups displayed in this figure are the only ones that have average earnings data available for 2021 in Yukon
[2] * denotes the industrial sectors and subsectors directly supplying labour to the Project.
Source: (Yukon Bureau of Statistics 2021b)

Figure 11-1. Average Weekly Earnings by Selected Industry Sector and Subsector for the Yukon, 2021

Median incomes may also be influenced by the Project. Currently, effects related to income distribution are expected to be more pronounced in smaller LSA and RSA communities that exhibit lower median individual incomes. Information regarding the individual median incomes for communities located in the LSA and RSA is presented in **Table *11-30*.**

Table 11-30. Median Individual Incomes for Communities Located within the Local Study Area and Regional Study Area Communities, in 2021

	Yukon	Whitehorse	Fort McPherson (NWT)	Dawson
Total	$54,800	$59,200	$31,200	$49,600
Male	$56,400	$61,200	$28,200	$51,600
Female	$53,600	$57,200	$35,600	$46,800

Notes:
[1]Information related to the individual median income for the communities of Old Crow and Mayo was not available online.
Source: (Government of Canada 2022)

11.5.2.2 Demand for Local and Regional Goods and Services

Project-related effects on local and regional business opportunities are anticipated to be positive. Business and procurement opportunities are anticipated to be associated with all Project components. Specific information on business and procurement opportunities, such as contract amounts and timing, will be developed during detailed Project design. Potential opportunities may include, but are not limited to:

- drill rigs;
- drilling mud tanks, pumps, and mud mixing and separation systems;
- power generators;
- boilers;
- flare tanks and flare stack;
- blowout preventer accumulator system;
- fuel storage;
- well cement mixing and storage;
- storage bins for rock cuttings removed from the drilling mud;
- trailers for offices, first aid, rig crew sleeping quarters, water storage and treatment, sewage storage, and food waste incinerator;
- vehicle parts and service;
- heavy machinery;
- road maintenance equipment;
- camp catering;
- personnel transport;
- trucking services (e.g., fuel, water hauling, waste, and vacuum trucks);
- heaters;
- flow lines; and,
- metering equipment.

Through the Project Engagement Program, concerns were expressed about the ability of local and regional businesses to access Project-related business and procurement opportunities. These concerns were related to receiving information about Project opportunities in a timely manner (see **Section 2 Consultation and Engagement**).

Effects related to business opportunities in the communities located within the LSA and RSA can be divided into three categories:

- **Direct effects:** associated with direct employment and expenditures from the Project and industries supplying the Project with goods and services.
- **Indirect effects:** related to all industries comprising the Project's value chain that would supply goods and services used to directly supply the Project.
- **Induced effects:** associated with consumer and household spending wages and income arising directly or indirectly from the Project in the consumer and services industries, which in turn has the potential to create additional business opportunities within the LSA and RSA.

Businesses located within the LSA and RSA are likely to benefit from Project expenditure in goods and services, including but not limited to construction equipment, road maintenance equipment, trucking services, fuel, vehicle parts and service, provisions and groceries. The larger and more diversified economy of Whitehorse may offer a greatest range of the goods and services required by the Project.

The capacity of local and regional business that may benefit from Project-related employment and business opportunities depends on their ability to access these opportunities, as well as to meet Project procurement requirements. Further, the Project expects to source specialized services and equipment – typically not available in the Yukon – from Alberta, British Columbia, or the Northwest Territories. Drilling equipment and rigs, cementing equipment, wireline data logging equipment, and oilfield equipment rental are anticipated to be included in this category.

Overall, the net effect on local and regional business opportunities from Project demands for goods and services is expected to be positive. An increase in local and regional business and contracting opportunities is expected to contribute to the economic growth of the region.

In addition to direct business opportunities, indirect benefits are anticipated on local and regional businesses that would supply goods and services throughout the Project. The purchase of goods and services for the Project can result in an increase in the economic activity of supplying companies. Throughout the Project, construction, wholesale traders, transportation, and warehousing are among the industries likely to benefit most from the oil and gas industry's purchases of goods and services (e.g., transport trucking, water hauling, vacuum trucks, and drilling equipment). Indirect employment is expected to result in induced effects from spending of wages on goods and services. When wages and salaries are spent, the businesses that supply these consumers with goods and services experience an increase in economic activity (e.g., retail, hospitality, and other consumer sectors). Information related to the businesses, by industry sector in the Yukon, available to supply goods and services to the Project is presented in **Table 11-31**.

Table 11-31. Number of Businesses Available to Supply the Project by Industrial Sector in the Yukon, 2021

Industrial Sector	Number of Businesses
Mining, quarrying, and oil and gas extraction	667
Utilities and manufacturing	103
Construction	1,154
Wholesale trade	378
Retail trade	266
Transportation and warehousing	1,891
Professional, scientific, and technical services	813
Management of companies and enterprises: administrative and support services	72
Waste management and remediation services	426
Educational services	164
Health care and social assistance	1,273
Accommodation and food services	977
Other services (except public administration)	419

Notes:
Information related to the number of businesses by industry is only available at the territorial level.
Source: (Yukon Bureau of Statistics 2023).

11.5.2.3 Economic Diversity

Economic diversity is defined as the distribution of economic activities across various industries and sectors. Diversification can contribute to the region's economic sustainability and stability by helping to reduce potential adverse effects from external shocks or downturns in specific industries. Project demand for labour, goods, and services has the potential to create additional employment and business opportunities for specific industries in local and regional economies. Changes in the structure of the local and regional economies can also affect income levels, especially if there is a transition from lower-paid employment to higher-paid employment or vice versa.

The Project is expected to have a positive effect on the construction, wholesale traders, transportation, and warehousing sectors, as well as on industries supplying goods and services to those sectors. The increased demand for labour is expected to be covered by the labour force in the Yukon working in these sectors. As of 2021, the Yukon had 2,045 construction businesses, 865 transportation and warehousing companies, and 290 wholesale traders (Yukon Bureau of Statistics 2022).

The Yukon had a Gross Domestic Product (GDP) of $2,933 million in 2021. The largest contributor was the public administration sector, with $661.1 million in economic output, representing 23.1% of the Yukon's GDP. Depending on the proposed Project components and associated activities, the annual capital spending for the Project is anticipated to range between $15 million and $35 million per year, representing between 0.5% and 1.1% of the Yukon's GDP for 2021.

The economic sectors that may benefit from the Project are relatively small in comparison. In 2021, the construction sector represented 9.9% of the total GDP, transportation and warehousing represented 2.3%, and wholesale trade represented 1.3% of the GDP. Information related to the Yukon's GDP for 2021 is only available at a territorial scale (Yukon Bureau of Statistics 2021a).

The Project is anticipated to strengthen the local and regional, construction, whole sales, transport, and warehousing sectors. This is expected to contribute to strengthening the regional economy and the economic diversity of communities located within the LSA. Therefore, Project-related effects on local and regional economy diversity are expected to be positive and are not considered further in the assessment.

11.5.2.4 Territorial and Local Government Finances

The Project is anticipated to have a net positive effect over territorial and local government finances. The Project has the potential to indirectly contribute to the Government of Yukon and local government finances through payment of income taxes paid by individuals and businesses directly and indirectly benefiting employment and business opportunities arising from the Project. In turn, income tax contributions will depend on the changes of income levels of individuals and businesses within the LSA and RSA who are directly and indirectly benefiting from Project-related employment and business opportunities.

Considering the number of individuals and businesses expected to benefit from Project-related employment and business opportunities, changes in territorial and local government finances from income taxes are expected to be negligible and are not considered further in the assessment.

Although the Government of Yukon has an oil and gas extraction royalty program, no oil and gas production is currently occurring, and no royalties are being collected. Based on the anticipated level of oil and gas to be produced through the EFT program, the Project is not expecting to conduct payments for oil and gas royalties. Chance will monitor oil and gas production of the proposed wells (see **Section 1 Details of the Proposed Project**) and determine if and when royalty payments to the Government of Yukon are required. No Project-related effects on territorial and local government finances are expected from the payment of oil and gas royalties and are not carried forward in the assessment.

The Project will contribute to the finances of the territorial government through the payment of land lease fees. Since the Project is located on Crown lands, the Project is required to pay land lease fees to the Government of Yukon. The Project is anticipated to have a net positive effect on territorial and local governments finances from the payment of land lease fees. However, the amount the Project expects to pay for this concept will not be significant enough to alter the Government of Yukon finances.

Project demands for emergency services and road infrastructure has the potential to increase demands on community infrastructure and services and impose additional costs to territorial and local governments. Potential effects and mitigation measures for the potential effects to local and regional infrastructure and services are qualitatively assessed in the Community Infrastructure and Services VESEC (**Section 11.2**).

Community Infrastructure and Services VESEC (**Section 11.2**) does not identify any adverse effects on demand for physical infrastructure. The increased demand for emergency services is expected to be negligible and are not carried forward in the assessment.

11.5.3 Mitigation or Enhancement Measures

Mitigation measures include any practical means or measures implemented to avoid or reduce potential adverse socio-economic effects resulting from the Project. Proposed enhancement measures are intended to improve positive effects (i.e., Project benefits). Proposed enhancement measures for Employment and Economy were developed based on feedback gathered through the Project Engagement Program (see **Section 2 Consultation and Engagement**), industry best practices, and knowledge gained from previous projects with similar characteristics.

The selection of mitigation and enhancement measures for Employment and Economy was based on primary and secondary data collection, review of mitigation and enhancement measures, monitoring programs from previous projects with similar characteristics, and input provided by First Nations and residents through the Project's Engagement Program.

11.5.3.1 Local and Regional Employment Opportunities

The overall effects of Project-related components and activities on the regional economy are anticipated to be positive. The Project's demand for labour may result in some effects on local employment, as the Project will require labour from other industries. These effects are expected to be offset by an increase in employment and business opportunities throughout the duration of the Project. While mitigation is not required, the Project will develop strategies designed to enhance local and regional benefits by identifying opportunities to increase local direct employment and by promoting the procurement of Project-related goods and services from regional suppliers. For additional information, refer to **Section 1.4.13 Proposed Project Benefits.**

11.5.3.2 Local and Regional Recruitment Strategies

Opportunities exist for enhancing employment benefits in the region by increasing the percentage of direct employment for the Project from within the LSA and RSA. Proposed enhancement measures associated with local and regional recruitment strategies may include:

- Communicate with local and regional educational institutions and local and regional communities on training requirements for entry-level and trades positions within the Project to support the potential availability of training opportunities for local and regional residents.
- Promote the recruitment of qualified local and regional workers (e.g., First Nations Citizens and residents of potentially affected communities), including those aspiring to level entry positions.
- Develop culturally appropriate employment policies that enable First Nations Citizens to access potential employment opportunities and participate in traditional harvesting and cultural activities if and when appropriate. First Nations Citizens who intend to participate in these activities will be required to inform interested parties (e.g., supervisors and contractors) in advance so that work schedules can be adjusted accordingly.
- Communicate relevant information (e.g., qualifications, years of experience, certifications) promptly regarding potential Project- employment opportunities to help potential candidates to obtain necessary training and experience. Employment opportunities will be advertised through local organizations, local and territorial governments, community mural boards, social media platforms (e.g., Facebook), and the Project website.

In accordance with section 68 of the Yukon *Oil and Gas Act,* RSY 2002, c 162 (*YOGA*), the Project is required to establish benefits agreements outlining local and regional recruitment opportunities related to the Project. These agreements will identify employment and training opportunities for Yukon residents, especially for First Nations Citizens and residents of potentially affected communities (Government of Yukon 2002).

11.5.3.3 Local and Regional Procurement Strategies

There is the opportunity to enhance economic benefits in the region by increasing the proportion of Project-related goods and services procured from suppliers located within the LSA and RSA. Proposed enhancement measures related to local and regional procurement strategies may include:

- development of a procurement strategy that promotes the purchase of Project-related goods and services from local and regional suppliers; and,
- The Project will communicate information about any procurement opportunities, pre-qualification factors (e.g., safety certifications) and evaluation criteria in a timely manner, so that local and regional businesses have ample opportunity to prepare and seek any required qualifications before the start of the Project. Procurement opportunities will be advertised through local organizations, local and territorial governments, community mural boards, social media platforms (e.g., Facebook), and the Project website.

To meet the requirements of Section 68 of the *YOGA*, the Project will develop benefits agreements with potentially affected First Nations and communities detailing local and regional procurement opportunities associated with the Project. These agreements will identify opportunities available for Yukon-based businesses to provide goods and services to the Project (Government of Yukon 2002).

11.5.3.4 Engagement with Local and Territorial Governments

The Project will continue to engage with local and territorial governments to identify potential effects on community services and identify potential mitigation measures to avoid or minimize effects on service delivery. In addition to mitigating potential effects on service delivery, the measures identified in the Community Infrastructure and Services (**Section 11.2**) are expected to mitigate potential effects on local and regional finances from costs associated with disruption of community services and infrastructure.

Chance is committed to ongoing engagement to discuss potential benefits, uncertainty associated with assessment predictions, and unanticipated Project effects with potentially affected First Nations Citizens and residents of local communities. Chance will plan a follow-up program to support the identification and response to potential community and economic effects resulting from the Project. This will involve the review of results from Chance's follow-up programs as well as feedback from First Nations and local communities to provide direction on the adaptive management of Project design, mitigation and benefit enhancement measures related to potential socio-economic effects.

11.5.3.5 Summary of Enhancement Measures

A summary of potential effects and proposed mitigation (enhancement) measures are presented in **Table *11-32***. With proposed mitigation, no adverse residual effects to employment and economy are identified. Only positive effects are anticipated.

Table 11-32. Enhancement Measures for Employment and Economy

Potential Effect	Enhancement Measure	Project Component
Changes in employment opportunities	Recruitment strategy to increase local and regional employment.	Seismic exploration, drilling exploration, EFT and reclamation and closure
Changes in employment opportunities	Procurement policy to enhance local and regional business opportunities	Seismic exploration, drilling exploration, EFT and reclamation and closure
Changes in economic diversity	Recruitment strategy to increase local and regional employment.	Seismic exploration, drilling exploration, EFT and reclamation and closure
	Procurement policy to enhance local and regional business opportunities	
Changes in territorial and local government finances	Engagement with local and territorial governments to reduce costs associated with any disruption to service delivery	Seismic exploration, drilling exploration, EFT and reclamation and closure

11.5.4 Residual Effects Assessment

No adverse residual effects on employment and regional economy are likely to result from the Project. As such, no residual effects have been carried forward for further assessment. Similarly, no effects have been carried forward to the cumulative effects assessment.

12 EFFECTS MANAGEMENT

12.1 MANAGEMENT AND MONITORING PLANS

Management and monitoring plans and associated subplans will be developed for the Project as required, and will include safety, prevention, mitigation, management, and monitoring measures where appropriate. Developed plans may include, but not be limited to:

- Environmental Management Plan:
  - Spill Response Plan;
  - Erosion and Sediment Control Plan;
  - Water Management Plan;
  - Waste Management Plan; and,
  - Remedial Action Plan.
- Wildlife Management and Monitoring Plan:
  - Caribou Mitigation and Monitoring Plan; and,
  - Caribou Interaction Response Plan.
- Conceptual Reclamation and Closure Plan:
  - Wellsite Decommissioning and Abandonment Plan.
- Safety Management and Emergency Response Plan:
  - Blowout Prevention and Response Plan; and,
  - Medical Emergency Response Plan.
- Consultation and Engagement Plan.

12.1.1 Environmental Management Plan

The Environmental Management Plan (EMP) will describe the measures that are to be implemented by employees and contractors to minimize environmental risks and mitigate impacts. The EMP will cover the following environmental components/sub-plans:

- spill response;
- appropriate oil and fuel handling and storage;
- erosion and sediment control measures;
- water use management;
- waste management; and,
- remediation measures.

The spill contingency plan will include spill reporting procedures, types of spills and their potential impacts, spill response actions and resources, and reporting procedures. The water use plans will describe permitted water uses, sources, withdrawal limits, and measures to conform with permit conditions. The waste management planning will identify sources and types of hazardous and non-hazardous solid and liquid waste (e.g., fluid from drilling and extended flow testing, camp waste), management and mitigation actions, and measures to reduce waste.

The EMP will outline regulatory requirements with regard to the environmental components covered in the Plan, reporting agencies and contacts, record keeping, employee and contractor training, and the roles and responsibilities of employees and contractors for oversight and implementation of the EMP.

12.1.2 Wildlife Management and Monitoring Plan

The Wildlife Management and Monitoring Plan will identify terrestrial and aquatic species of conservation concern (e.g., caribou) that have the potential to be adversely affected by the Project and species-specific mitigation actions, how wildlife will be monitored during operations, and adaptive management actions if management targets are not being achieved. This will include actions to reduce human-wildlife conflict and to avoid impacts to important wildlife habitat features (e.g., active dens). The Wildlife Management and Monitoring Plan will also outline regulatory requirements, reporting agencies and contacts, record keeping, employee and contractor training, and the roles and responsibilities of employees and contractors for oversight and implementation of the Wildlife Management and Monitoring Plan and subplans.

12.1.3 Conceptual Reclamation and Closure Plan

Chance plans to complete progressive abandonment, decommissioning, reclamation, and closure activities during and following the life of the Project. The Conceptual Reclamation and Closure Plan will outline the timeline and measures used to reclaim the winter roads, appropriately suspend and abandoned wells and well pads, seismic lines, and clearings due to accessory activities, following appropriate legislation. The plan will also include monitoring and adaptive management measures for reclamation success.

12.1.4 Health, Safety and Emergency Response Plan

A comprehensive Health, Safety and Emergency Response Plan (HS/ERP) will be developed for the Project and may include the following components and subplans related to occupational health, hazard assessment, safety procedures and emergency response preparation:

- safety training requirements;
- hazard assessment planning;
- evacuation procedures;
- well blowout prevention and procedures;
- fire response planning; and,
- medical emergency response planning.

12.1.5 Consultation and Engagement Plan

The Consultation and Engagement Plan will describe how Chance will engage with affected communities and groups prior to commencing work and during the life of the Project. The Consultation and Engagement Plan will identify affected communities and groups, including Indigenous organizations/governments, and the engagement strategy for each affected party. Chance employees or contractors responsible for consultation and engagement activities will be identified. The Consultation and Engagement Plan will also describe how records of consultation, comments received, and follow-up actions will be tracked.

12.2 FOLLOW UP MONITORING

Management and monitoring plans and associated subplans, as described above, will be developed for the Project, as necessary. The plans are required as part of Project design and all Project activities, and will consider potential environmental and socio-economic effects, effectiveness of applied mitigation measures, and will include adaptive management measures and associated follow-up monitoring requirements.

Section 12 Effects Management

No references

APPENDIX A. Designated Office Evaluation Report, YESAB, February 9, 2016

YESAB
Yukon Environmental and
Socio-economic Assessment Board

Designated Office Evaluation Report

Eagle Plains Multi-Well Exploration Program

Project Number: 2014-0112

Proponent: Northern Cross (Yukon) Ltd.

Assessment Completion Date: February 9, 2016

Dawson City Designated Office

Bag 6050
Dawson City, YT Y0B 1G0
Tel: (867) 993–4040
Fax: (867) 993–4049
www.yesab.ca

Executive Summary

Northern Cross (Yukon), the Proponent, is proposing to drill twenty wells for oil and gas extraction in the Eagle Plains basin over an area of up to 700 km^2. In order to test the potential productive capacity of oil and gas reservoirs, the Project proposes extended flow tests for a period of up to two years per well drilled. The Proponent expects that these tests will produce a combined likely maximum of 4 000 barrels (636 000 L) of oil per day. A number of auxiliary activities are also proposed.

A central value of the assessment is the way of life of First Nations and the Inuvialuit as it relates to the Porcupine Caribou Herd (PCH). This value represents a number of interrelated and codependent sociocultural values including: community health and vitality; cultural identity and continuity; food security; and traditional economy. The Project may result in changes in access to and use of the PCH by First Nations and the Inuvialuit. The Designated Office has focused its analysis on access to and use of the PCH by FN and the Inuvialuit in order to assess potential adverse effects to this central value.

The Porcupine Caribou Management Board states that the "Porcupine Caribou are the most valued ecosystem component in the project area and are likely one of the most valued ecosystem components for the whole northern Yukon, portions of the NWT, and Alaska. Harvesting provides communities with traditional healthy food options that are directly tied to the maintenance of cultural practices, as the communities, First Nations, and Inuvialuit utilize this important resource" (YOR 2014-0112-133-1). First Nation communities that value access to and use of the PCH for their community health and vitality, cultural identity and continuity, food security and traditional economy include the:

- First Nation of Na-Cho Nyäk Dun
- Inuvialuit
- Tetlit Gwich'in Council
- Tr'ondëk Hwëch'in
- Vuntut Gwitchin First Nation

In attempting to understand whether the Project will, or is likely to have, significant adverse socio-economic effects to this value, the Designated Office considered:

- the proposed scope of activities;
- relevant proponent mitigations;
- baseline information related to access to and use of the Porcupine Caribou Herd;
- baseline information related to the Porcupine Caribou Herd;
- the North Yukon Regional Land Use Plan;
- current Porcupine Caribou interaction with the project area;

- consequences of Porcupine Caribou interaction with the Project including an examination of the potential zones of influence of the project and the potential magnitude, probability, duration, extent and reversibility of project effects; and

- the potential significance and probability of scenarios ranging from the best to the worst-case for how this Project could affect access to and use of the Porcupine Caribou Herd.

In considering this information, the Designated Office makes a number of conclusions. First, there is insufficient information to understand pre-development conditions for access to and use of the PCH and for the PCH. Second, while the North Yukon Regional Land Use Plan (NYRLUP) provides valuable guidance, there are a number of outstanding priorities that remain unaddressed by the parties to the NYRLUP.

The Designated Office is unable to determine if the Project will, or is likely to have, significant adverse sociocultural effects. The Designated Office is able to determine the significance of adverse environmental effects directly to the PCH, such as direct habitat loss and injury/mortality, from the Project; however, the Designated Office is unable to predict how the PCH will interact with the Project and as such is unable to determine the significance of adverse sociocultural effects related to the access to and use of the PCH.

The inability of the Designated Office to determine the significance of adverse sociocultural effects is rooted in an inability to predict changes in baseline movement, migration, and occupancy of the PCH as a result of project activities. Specifically, the Designated Office is unable to determine the probability or magnitude of changes to caribou migration and seasonal distribution in relation to project activities and the associated duration, reversibility, and extent of such effects. Therefore, the Designated Office is unable to determine the significance of adverse effects to these sociocultural values.

Assessment Outcome

Under s. 56(1)(d) of the *Yukon Environmental and Socio-economic Assessment Act*, the Dawson City Designated Office refers the Project to the Executive Committee for a screening, as after taking into account any mitigative measures included in the project proposal, the Designated Office could not determine whether the Project will have, or is likely to have, significant adverse socio-economic effects.

10.2 WORST-CASE SCENARIO 12
11.0 Conclusion 14
Appendix A Project Location, Scope and Proponent Mitigations 17
Appendix B Baseline Information Related to Access To and Use Of the Porcupine Caribou Herd 32
Appendix C Baseline Information Related to the Porcupine Caribou Herd 43
Appendix D Zone of Influence 53
Appendix E Consideration of the North Yukon Regional Land Use Plan 55

1.0 REQUIREMENT FOR AN ASSESSMENT

The purpose of the Eagle Plains Multi-well Exploration Program ("the Project") is to explore and delineate the extent of hydrocarbons within the project area using extended flow tests. While several activities are likely to be undertaken in conjunction with this Project, under s. 47 of the *Yukon Environmental and Socio-economic Assessment Act* (YESAA), the Project is subject to an assessment by the Dawson City Designated Office due to the following circumstances:

- The proposed activity is listed in column 1 of Schedule 1 of the *Assessable Activities, Exceptions and Executive Committee Projects Regulations* (Activity Regulations) and not listed in column 2 as excepted. The proponent proposes to undertake activities listed in Part 3, item 1 of the Activity Regulations. The specific activity is listed as:

  On other than an Indian reserve, exploration for oil or natural gas, or other activity in relation to exploration for oil or natural gas

- Is proposed to be undertaken in Yukon; and
- An authorization or the grant of an interest in land by a government agency, independent regulatory agency, municipal government, or First Nation is required for the activity to be undertaken.

The Decision Body for this Project and associated triggering authorization for this assessment are indicated in Table 1.

Table 1: The Decision Body

Decision Body	Authorization Required	Act or Regulation
Government of Yukon, EMR – Oil and Gas Branch	Well License	*Oil and Gas Act*

2.0 REFERRAL CRITERIA

Under YESAA, Section 56(1), the Designated Office must refer a Project to the Executive Committee for a screening where

> "after taking into account any mitigative measures included in the project proposal, it cannot determine whether the project will have, or is likely to have, significant adverse environmental or socio-economic effects."

The outcome of this assessment, to refer the Project to the Executive Committee, does not require consideration of potential mitigations to reduce significance. Potential mitigations can only be considered if there are significant adverse effects. The Designated Office is unable to determine if adverse effects are significant and therefore, is unable to consider potential mitigations not included in the proposal.

3.0 CONSIDERATION OF SIGNIFICANCE

In order to mitigate a potential adverse effect, the Designated Office must first find significance. In addressing what may constitute a "significant" adverse effect, the Designated Office considered the following factors:

Magnitude: The intensity of an effect or extent of change, where "effect" is defined as the change from baseline conditions resulting from an activity.

Probability: The likelihood that an adverse effect will occur.

Duration: The length of time the effect lasts and how often the effect occurs. The duration of an effect can be short term or long term.

Geographic Extent: The geographic extent of project effects (e.g. the distance from the project and/or the area in which effects are detectable). The geographic extent of effects can be local or regional.

Reversibility: The degree to which the effect is reversible. Effects can be reversible or permanent. Reversible effects may have lower impacts than irreversible or permanent effects.

Context: The particular environmental and/or socio-economic context within which the project occurs. Context is related to the importance of valued environmental and socio-economic components, their resiliency to potential effects and the extent to which those valued components may successfully adapt to change.

4.0 VALUES CONSIDERED IN THE ASSESSMENT

The assessment of this Project considered a number of valued environmental and socio-economic components. Valued environmental components include:

- Air Quality
- Aquatic Resources
- Avian Wildlife
- Climate Change
- Water Quality and Quantity
- Wildlife and Wildlife Habitat, excluding access to, and use of, the Porcupine Caribou Herd, but including: black bears; fur-bearers; grizzly bears; moose; and wolf

Valued socio-economic components include:

- Access to, and use of, the Porcupine Caribou Herd, including the following sociocultural values that reflect the way of life of First Nations and the Inuvialuit: community health and vitality; cultural identity and continuity; food security; and traditional economy
- Heritage Resources
- Human Health and Safety
- Traditional Land Use, excluding access to, and use of, the Porcupine Caribou Herd, but including: trapping; fishing; harvesting of plants and animals; and traditional pursuits.

The Designated Office is able to determine significance of effects to – and mitigate in the event of significant adverse effects – all of the above valued components with the exception of access to and use of the PCH. As the Designated Office is unable to determine the significance of adverse effects to the access to and use of the PCH, the Designated Office is required to refer the Project to the Executive Committee under section 56(1)(d) of YESAA. As this value is the only value for which the Designated Office is unable to determine significance, this evaluation report focuses on this value exclusively.

Structure of the Referral

This evaluation report outlines the:

- value of access to and use of the Porcupine Caribou Herd (section 5.0);
- Porcupine Caribou Herd, its characteristics, and baseline properties (section 6.0);
- current interaction of Porcupine Caribou with the project area (section 7.0);
- project activities (section 8.0);
- consequence of Porcupine Caribou interaction with the Project (section 9.0)
- significance analysis conducted by the Designated Office (section 10.0); and
- conclusions of the assessment (section 11.0).

This report also includes the following appendices:

- project location, scope and proponent mitigations (Appendix A);
- baseline information related to access to and use of the Porcupine Caribou Herd (Appendix B);
- baseline information related to the Porcupine Caribou Herd (Appendix C);
- zone of influence (Appendix D); and
- consideration of the North Yukon Regional Land Use Plan (Appendix E).

5.0 VALUE OF ACCESS TO AND USE OF THE PORCUPINE CARIBOU HERD

Access to and use of caribou, for social, cultural, health, and traditional economy purposes, is a central value in evaluating the effects of the Project. Appendix B provides a summary of information gathered by the Designated Office to understand baseline conditions for how First Nations and the Inuvialuit access and use the PCH.

The NYRLUP speaks prominently to the social, cultural, and economic reasons behind the value of the PCH. The guiding principle of the NYRLUP is “beneficial socio-economic change that does not undermine the ecological and social systems upon which communities and societies are dependent” (North Yukon Planning Commission, 2009). The Porcupine Caribou Management Board (PCMB) also gives prominence to the social and cultural values associated with access to caribou, for harvest or cultural transmission. A Vuntut Gwitchin First Nation (VGFN) comment best demonstrates the role of caribou being a fundamental

part of their culture, “The Creator gave the Gwich’in the Caribou to feed and sustain the people, and to keep the teachings and responsibilities to our past, current and future generations alive” (North Yukon Planning Commission, 2009).

Given the central role of the PCH in community health and vitality, cultural identity and continuity, food security, and traditional economy of First Nations and the Inuvialuit, the Designated Office requires a high degree of confidence in both effects predictions and significance determinations. When the PCH suffers, First Nation and Inuvialuit communities that rely on the herd, and have relied on for centuries, also suffer.

6.0 DESCRIPTION OF THE PORCUPINE CARIBOU HERD

Background

The PCH is a migratory barren ground subspecies of caribou, *Rangifer tarandus granti*. The herd ranges along the Arctic Coast from Alaska, through Yukon, into Northwest Territories and stretches south towards the Ogilvie and Richardson mountains. Appendix C provides a summary of information gathered by the Designated Office to understand baseline conditions for the PCH.

The herd’s population is estimated at 197 000, but with a wide confidence interval. The PCMB has a management objective for the herd population of 135 000. Baseline herd population levels are believed to be cyclical and are expected to decrease in the near future.

In relation to other barren-ground caribou herds, the PCH has the lowest capacity for growth. An Alaskan study concludes that the PCH capacity for growth is 4.9 percent, while other Arctic herds were significantly higher (Central Arctic herd 10.8 percent, Teshekpuk Lake herd 13 percent, and Western Arctic herd 9.5 percent) (USGS, 2002). The low growth rate indicates that the PCH has less capacity to accommodate anthropogenic, biological, and abiotic stresses than other barren-ground herds. As a result, any absolute effect of development would be expected to have a larger relative effect on the PCH than on other herds.

The overall population and health of the PCH is shaped by both natural effects such as forest fire and climate change, as well as anthropogenic effects, such as harvesting and industrial development.

Life history

The Arctic National Wildlife Refuge in Alaska provides critical calving and summer habitat for the PCH. Calving generally occurs during late May to mid-June annually. The post calving period is from mid/late June to July. In August, and extending until mid-October, the herd's annual fall migration begins as the PCH moves towards the wintering grounds south of the Brooks Range in Alaska and the southern Richardson and Ogilvie Mountain Ranges in Yukon. Rutting occurs for about a two week period in mid-October, after which the herd continues migrating towards the winter ranges. In the spring, migration back to the calving grounds begins in early March, with the PCH generally following three broad routes north (see Figures 9, 11 and 13 – 15 in Appendix C).

Winter is considered a difficult time for the PCH, as food sources, such as lichen, are covered in snow and can be difficult to access. In addition, the plants themselves are not as nutritious or as easily digested by the animals at this time of the year. Russell notes “whatever happens to the PCH in the winter affects the calf survival numbers, affects the pregnancy the next year, and virtually every aspect of productivity from age of first reproduction to calf survival. Winter is not considered a limiting factor for herd productivity as it is with woodland caribou herds in southern Yukon” (YOR 2014-0112-133-1).

There is overlap between the preferred winter habitat and migration routes of the PCH and the project area. The extent of high-quality winter habitat in the project area is currently unknown, as is the importance of migratory routes that overlap the project area.

7.0 CURRENT PORCUPINE CARIBOU INTERACTION WITH THE PROJECT AREA

The PCH may migrate through the area of the proposed Project in October and November while on their way to more southern wintering areas along the Ogilvie River and surrounding areas, and then may pass through the Project area again in the spring on their way north towards the calving grounds. The PCH may also choose to over-winter in the project area or its vicinity.

In any given year, there is approximately a fifty percent chance of Porcupine Caribou occupying the project area. The PCMB indicates that there may be wide use of the project area from tens of thousands of animals, to small or no groups of caribou, in a given year, and that the period of PCH presence in the project area may vary from days to all winter. During the winter of 2015, up to three quarters of the herd was in close proximity to the Dempster Highway; up to 50 000 caribou passed directly through the project area (YOR 2014-0112-267-1).

The project area is primarily a winter migration corridor for the PCH, though it may have other habitat functions for caribou in any given year. The project area straddles the divide between the Peel and Porcupine drainages; this ridgeline appears as a natural corridor for caribou movement. The Designated Office is not aware of other specific migratory corridors in the vicinity of the Project.

Natural factors and climate change

Baseline herd interaction with the project area will be modified due to the effects of climate change. The project area – and northern areas in general – is projected to experience climate change faster with greater intensity than more moderate latitudes. Climate change will result in increased variability in PCH movement, migration, and occupancy.

Natural baseline interaction between the PCH and the project area is variable due to a number of occurring factors such as snow, insect presence, temperatures, and forest fires. The project area was largely burned in the 2000s (see Figure 16 in Appendix C).

Existing disturbance

The project area has a history of oil and gas exploration. Nearly 40 wells have been drilled in the Eagle Plain basin, predominately in the 1960s and 1970s. Only five wells have been drilled since 2000, one in 2005 and four others by the Proponent in 2012. In addition to existing wells, approximately 14 000 km of seismic lines exist in the Eagle Plain basin. The project area also contains an existing authorized camp capable of housing 75 people.

The Dempster Highway was constructed through the project area in the 1960s and 1970s. To the north of the Project, 60 km away, is the Eagle Plains Lodge.

8.0 PROJECT ACTIVITIES

The Project takes place within the area of the NYRLUP. Specifically the Project is proposed in Land Use Management area 9, zone IV, which is designated for “highest development”. The Project proposes the

drilling of 20 wells across an area of approximately 700 square kilometers.[1] Support activities for the construction and maintenance of these wells includes the construction of up to 87 km of all season roads, development of 23 quarries, and the construction of a mix-bury-cover sump (see Appendix A.2. for a project scope and A.3. for a detailed description of project activities).

Extended flow testing will last for up to two years. These tests require daily access, flaring of gas (up to 2 000 000 cubic feet per day or 5 700 m^3 per day), installation of pump jacks and surface equipment, and up to 20 round trips per day by tanker to and from the Project. A central processing facility is also required. The Project will produce up to an estimated 4 000 barrels (646 000 L) of oil per day. The Project will also require two round trips by aircraft per week.

9.0 CONSEQUENCES OF PORCUPINE CARIBOU INTERACTION WITH THE PROJECT

Herd interaction with Project activities

The Proponent states that the Project will disturb caribou movements due to sensory disturbance (YOR 2014-0112-201-1). Caribou movement through the project area will be affected by a zone of influence (ZOI) surrounding the Project.

A ZOI refers to the effective area of an activity or disturbance. Developments not only exclude wildlife from their physical footprint, but also reduce the use and functionality of surrounding areas, resulting in habitat degradation through reductions in suitability. The magnitude of such effects depends on land uses and the rate at which related adverse effects decrease with distance from a project.

The ZOI for projects involving the Porcupine Caribou, or other caribou subspecies, is unclear at best and unknown at worst. Studies of potential ZOI around industrial projects in the north have demonstrated that the ZOI is not a fixed width, but rather that it changes over time given the season, animal characteristics such as age and sex, and intensity of the land use by human activities (see Appendix D for further information on ZOI).

The Project, and its associated ZOI, will likely reduce caribou occupancy and movement through the project area and along the migration corridor that bisects the project area. This effect may diminish after project completion. The magnitude of this effect, however, remains unclear.

There is a wide range of potential changes to movement, migration, and distribution of the PCH due to project activities. Different outcomes may result in significantly different effects for users of the PCH.

Direct sociocultural consequences

Changes to the migration routes of the PCH could result in fewer caribou in proximity to the Dempster Highway. The Dempster Highway is one of three key zones for accessing and harvesting Porcupine Caribou (see Appendix B, Figure 5 and 6). This change may in turn result in reduced access to and use of the PCH. This reduction may adversely affect hunter success and food security, traditional economy,

[1] Proposal documents state that the Project's area is 325 km^2; however, the Designated Office has determined that the proposed Project covers an area of 700 km^2. This was based on comparing proposed activities to those in the previous project, a 3D seismic survey (YOR 2013-0067). More details on this determination are available in Appendix A.1.

individual and community health and the opportunity for intergenerational transfer of knowledge and culture. Ultimately, this reduction may affect the way of life of First Nations and the Inuvialuit.

Herd level changes and indirect sociocultural consequences

Changes to migration routes can also result in occupancy of lesser quality habitats, increased encounters with predators, and disrupted life cycles. Changes to migration routes that change population dynamics may or may not result in sociocultural effects in either the short or long term.

Potential magnitude of effects

Changes in herd migration, distribution, and occupancy are likely as a result of project activities. The potential variation in the magnitude of changes to herd migration, distribution, and occupancy ranges between the following extreme outcomes:

- almost no change in access to and use of caribou – if migration is shifted to other areas in close proximity to the Dempster Highway; or
- to reduced access or no access to and use of caribou – if migration is shifted to other areas that are not in proximity to the Dempster Highway.

Probability of effects

Each potential magnitude of effect has an accompanying probability. The probabilities for each magnitude are unknown. The Designated Office is unable to determine how the herd might respond to the Project, which in turn makes predictions on probable effects impossible.

Herd response to development in the Eagle Plain basin is unknown, but is vitally important to the effects assessment.

The NYRLUP prioritizes further investigation of cause and effect relationships for recommended cumulative effects indicators, including:

- relationship between barren-ground caribou and land use activities, with focus on range utilization in response to surface disturbance and linear density;
- cumulative impacts of exploration and development activities on Porcupine Caribou Herd population viability; and,
- cumulative surface disturbance impacts and potential effects on habitat quantity and quality.

These priorities have not been addressed. The most recent annual report for the NYRLUP still prioritizes, in 2015, the collection of baseline data required to assess cumulative effects and developmental thresholds. Further, the Government of Yukon and VGFN still prioritize the research of "caribou related issues to address concerns related to exploration activities in the Eagle Plain region including the development of Best Management Practices as guidance to oil and gas activities and a process to establish safe operating distances and critical numbers for the Porcupine Caribou Herd" (Government of Yukon and VGFN, 2014).

The PCMB states that neither best management practices nor mitigations for caribou avoidance are known, further limiting the Designated Office's ability to determine how the Project's design and commitments influence the probability of adverse effects to caribou migration.

Based on information available to the Designated Office, both extreme ends for the range of potential magnitudes are equally probable.

Duration of project effects

The likely duration of project effects hinges upon both the magnitude and the probability of effects to the access to and use of the PCH. The duration of effects to the access to and use of the PCH is not dependent on the duration of project activities. Effects that have a larger magnitude and higher probability may result in changes to caribou migration and occupancy that may endure for longer durations.

Extent of project effects

The geographic extent of project effects hinges upon both the magnitude and probability of project effects to the access to and use of the PCH. The Project may cause potential variation in the magnitude of changes to herd migration, distribution, and occupancy ranges. The resulting extent of effects on access to and use of the PCH is equally variable in terms of geographic extent (see Appendix D for further information).

Reversibility of project effects

The reversibility of project effects hinges upon both the magnitude and probability of project effects to the access to and use of the PCH. Reversibility of effects to cultural continuity depends on duration as well. Effects that have a larger magnitude and higher probability will be less reversible, especially if cultural traditions, community well-being, and traditional economies are affected.

Contrast with similar effects assessments

Unlike previous assessments involving effects to caribou, the magnitude and probability of project adverse effects in this case are not proportional to the project size or intensity. Projects undertaken within the range of non-migratory herds have effects that are generally proportional to the size and intensity of the Project. In considering a migratory herd, the adverse effects of a Project may result in changes to migratory patterns that result in disproportional changes to habitat use and range extent. The Project is an outlier compared with previous development in the region and thus it is possible that the Project may result in disproportionate effects to caribou migration, occupancy, and distribution.

10.0 SIGNIFICANCE INDETERMINATION

The Designated Office cannot determine the magnitude of the adverse effects; it can, however, determine a range of magnitudes. Likewise, the Designated Office cannot determine the probability of adverse effects to the access to and use of the PCH.

Given the range of magnitude of adverse effects, the Project may or may not result in significant adverse effects. The Designated Office, using available information, considers both extremes, the best and worst scenarios as having equal probabilities.

In the absence of any confidence in the relevant parameters used in assessment (i.e. magnitude, probability, duration, reversibility), the Designated Office is unable to determine if the Project will result, or is likely to result, in significant adverse effects.

Consideration of Proponent mitigations

The Designated Office considered the relevant mitigations proposed by the Proponent to eliminate, reduce or control potential adverse effects of the Project to access to and use of the PCH (see Appendix A.4.). The Designated Office concludes that there are no mitigations related to access to and use of the PCH – the mitigation measures listed relate specifically to the PCH or to wildlife in general.

The Designated Office requested information from the Proponent to determine the current and traditional use of the project area by affected First Nations and possible mitigations for effects to current uses. The Proponent's response was cursory – in part, the Proponent responded that "Traditional uses of the area will be able to continue outside of the footprint of the Project and hunting with firearms can continue within the bounds identified in the Yukon Hunting Regulations" (YOR 2014-0112-199-1).

10.1 Best-case Scenario

A project best-case scenario results in no change to access to and use of the PCH. The best-case scenario is possible if:

- Changes to caribou distribution, migration, and occupancy
    - result in no change to access to caribou along the Dempster Highway;

  or

- The caribou naturally avoid the project area for the duration of the Project as a result of environmental factors, eliminating the interaction between the Project and the PCH.

The best-case scenario(s) represents an unchanged or minimal change to baseline conditions.

Significance determination of best-case scenario

The best-case scenario represents an undetectable or minimal change from baseline conditions. These changes by definition are not significant.

Probability of best-case scenario

A range of factors increases the probability of the best-case scenario. Most notably, the NYRLUP states that "specific recommendations relating to the management of oil and gas exploration and development activities are not required at this time."

Further, the project area has been a site of historic oil and gas development since the 1950s. Despite the Proponent's previous seismic survey, caribou were present in the project area numbering in the tens of thousands. The project area itself is also largely burned, resulting in less valuable habitat. The stochastic nature of PCH migration also suggests that the landscape hosts alternative or redundant habitats in a patchwork configuration.

10.2 Worst-case Scenario

The project worst-case scenario results in changes to caribou distribution, migration, and occupancy that reduces caribou presence in proximity to the Dempster Highway, reducing or eliminating access to and use of the PCH along the Dempster Highway. Alternatively disturbance effects resulting in changes in distribution, migration and occupancy may result in reductions in essential caribou habitat.

The worst-case scenario represents a significant reduction or complete elimination of access to and use of the PCH, through displacement of the herd, or reduction in the herd's long-term health and viability due to project-related changes in occupied habitat and range.

Significance determination of worst-case scenario

In the event of changes to the distribution, occupancy, and migration of the PCH that greatly reduce or eliminate caribou in proximity to the Dempster Highway, the magnitude of the effect is the complete, or nearly complete, elimination of the access to and use of the PCH in this region. The magnitude of this effect severs First Nations' and the Inuvialuit's connection with the herd. Effects to community health and vitality, cultural identity and continuity, food security, and traditional economy may be irreversible due to the central role of the PCH to these fundamental values and the way of life of First Nations and the Inuvialuit.

Changes to caribou behaviour may only return to baseline conditions in the long-term. In the worst-case scenario, the magnitude of this change results in abandonment or severe reduction in use of a large portion of winter habitat.

Comments received by Renewable Resource Councils and First Nations reinforce the significance of worse or worst-case scenarios. The Mayo Renewable Resource Council states "The large foot print and time scope of this Project could permanently adjust or eliminate the caribou migratory pattern through this area, to the disadvantage of the First Nations subsistence hunters and all others" (YOR 2014-0112-243-1). The Gwich'in Tribal Council further elaborates on the potential significance of a worse or worst-case scenario,

> Without regular use of sites the knowledge of those sites may diminish over time as knowledge is forgotten or not passed on to newer generations. At a certain temporal range, an environmental effect that prevents a harvester from accessing a traditional site or seasonal round may mean that such site specific practices are lost for a much longer duration than the project effect lasts for in the biophysical sense. (YOR 2014-0112-127-1)

Most succinctly, one comment from a VGFN citizen clearly states the significance of a worst case scenario, "it could lead to the permanent destruction of what I hold most closely to my heart" (YOR 2014-0112-109-1).[2]

The PCMB indicate that the PCH population will likely enter a downward phase during the life of the Project due to natural cyclical patterns, reducing baseline caribou presence along the Dempster Highway and increasing the severity of the worst-case scenario (YOR 2014-0112-133-1).

The Designated Office determined that these effects are significant and adverse because project effects would result in a complete, or near complete, elimination of access to and use of the PCH. This represents a significant departure from baseline conditions, as they are currently understood.

[2] The comment continues: "Not only does my standpoint come from a concern that this project will adversely affect the environment, it also stems from the fact that Northern Cross's proposal will degrade my sense of place and my connection with the land. My ancestors have used this land for their physical, spiritual and cultural sustenance for countless generations and I would like to afford the same privilege to my children and grandchildren some day; therefore I would like to see the project rejected."

Probability of worst-case scenario

A range of factors increases the probability of the worst-case scenario. Comments from stakeholders suggest that the worst-case scenario is, at the very least, probable. The potential intensity of land use includes the combustion of up to 2 000 000 cubic feet of gas per day by flaring, such activities may increase the ZOI through effects to air quality. Regardless, ZOI for heavy industrial development, including the construction of the Dempster Highway, suggest avoidance distances of up to 30 km. Research on the Dempster Highway's ZOI suggests that they are long lived.

The large ZOI, along with increased heavy traffic, make a disproportionate impact by the Project on land use patterns of caribou increasingly likely, especially as the Project is located in the only known migration corridor in the immediate vicinity. Alternative migration corridors may be far from existing preferred routes.

The Proponent will not cease all project activities in the event of large scale caribou presence within the project area – without aerial surveys it may not be possible to determine thresholds for adaptive management plans in any event – which further increases the risk of the Project interfering or disrupting caribou distribution, occupancy, and migration.

A worst-case scenario's probability is increased by the unprecedented proposed intensity of land use in an area with a relatively low level of industrial development. The Project is an escalation of land use intensity that reduces the reliability of making predictions based on previous experience, lowering the probability of a best case scenario.

11.0 CONCLUSION

The Designated Office is unable to determine if adverse effects to the access to and use of the PCH are or are not significant. Consequently, the Designated Office must refer the Project to the Executive Committee for screening.

As noted, the Project takes place within the area of the NYRLUP. Specifically the Project is proposed in Land Use Management area 9, zone IV, which is designated for "highest development"; however, industrial development must still take place within the parameters laid out by the plan, which notes that there is a need for coordinated and effective management of PCH habitat and population, prior to industrial development. The Plan also notes that industrial development may lead to land use conflicts between industrial development on one hand and the PCH and land users on the other. The most recent annual report for the NYRLUP stresses the need for baseline data collection and development of best management practices in order to better understand and predict effects. Industrial development in the region is predicated upon fulfillment of goals for information collection as set out in the NYRLUP and associated annual reports.

Many comments build on the priorities of the NYRLUP: development in the region is not intrinsically adverse, but rather that additional information is required to make confident effects predictions and to determine the significance of those adverse effects. The requirement for confidence in predicting effects in this assessment is elevated for two reasons: first, the significant importance for the First Nation and the Inuvialuit way of life that is intrinsically linked to the PCH; and second, the unprecedented scale of the Project within this region.

Information that would have helped to inform this assessment includes the following:

- Access to and use of the Porcupine Caribou Herd by First Nations and the Inuvialuit in relation to the project area and potential zones of influence from project activities.
- Relationship between barren-ground caribou and land use activities, with focus on range utilization in response to surface disturbance and linear density.
- Baseline data to assess cumulative effects and developmental thresholds (e.g. cumulative surface disturbance impacts and potential effects on habitat quantity and quality).
- Cumulative impacts of exploration and development activities on access to and use of the Porcupine Caribou Herd by First Nations and the Inuvialuit.
- Development of Best Management Practices as guidance to oil and gas activities in relation to the Porcupine Caribou Herd (Government of Yukon and VGFN, 2014).
- A process to establish safe operating distances and critical numbers for the Porcupine Caribou Herd (Government of Yukon and VGFN, 2014).

Appendix A PROJECT LOCATION, SCOPE AND PROPONENT MITIGATIONS

A.1. PROJECT LOCATION

The Designated Office scoped the Project as covering an area of 700 km^2. The scoped area is defined by a previous Project conducted by the Proponent, a 3D seismic survey (YOR 2013-0067).[3] Some Project activities will take place outside of this area and these activities include: water withdrawals, data collection, and transportation of materials to or from the Project area.

The Project area is approximately 30 km south of Eagle Plains and straddles the Dempster Highway. The Project area also straddles the drainage divide between the Peel and Porcupine rivers; however, the vast majority of the Project area, including all proposed drill sites, is located in the Porcupine River watershed.

The Project will take place in the traditional territories of the First Nation of Nacho Nyäk Dun (FNNND) and VGFN as well as in the Tetlit Gwich`in Council's (TGC) Secondary Use Area. Figure 1 provides an overview of the Project in relation to First Nation Settlement Lands and use areas.

The Project is in the North Yukon Planning Region. Table 2 provides an overview of information on the Project location.

Table 2: Project location, coordinates, and geographical paramaters

[3] Project 2013-0067 resulted in a 3D seismic over a portion of the 700 km^2 assessed. The Project, 2014-0112, proposes wells within this same portion; however, roads and quarries are proposed outside of this portion but within the 700 km^2 area. The portion that was actually surveyed is greater than 325 km^2 as it is closer to 400 km^2. Further supporting a 700 km^2 assessment area, "Twenty exploratory wells program within the 3D seismic area assessed under YESAB project 2013-0067" (2014-0112-073-1). Proposal documents for the 3D seismic survey confirm that the seismic area is 700.87km^2 (2013-0067-003-1). It is possible that the location of the camp, at km 325 of the Dempster Highway, was confused with the project area in proposal documents.

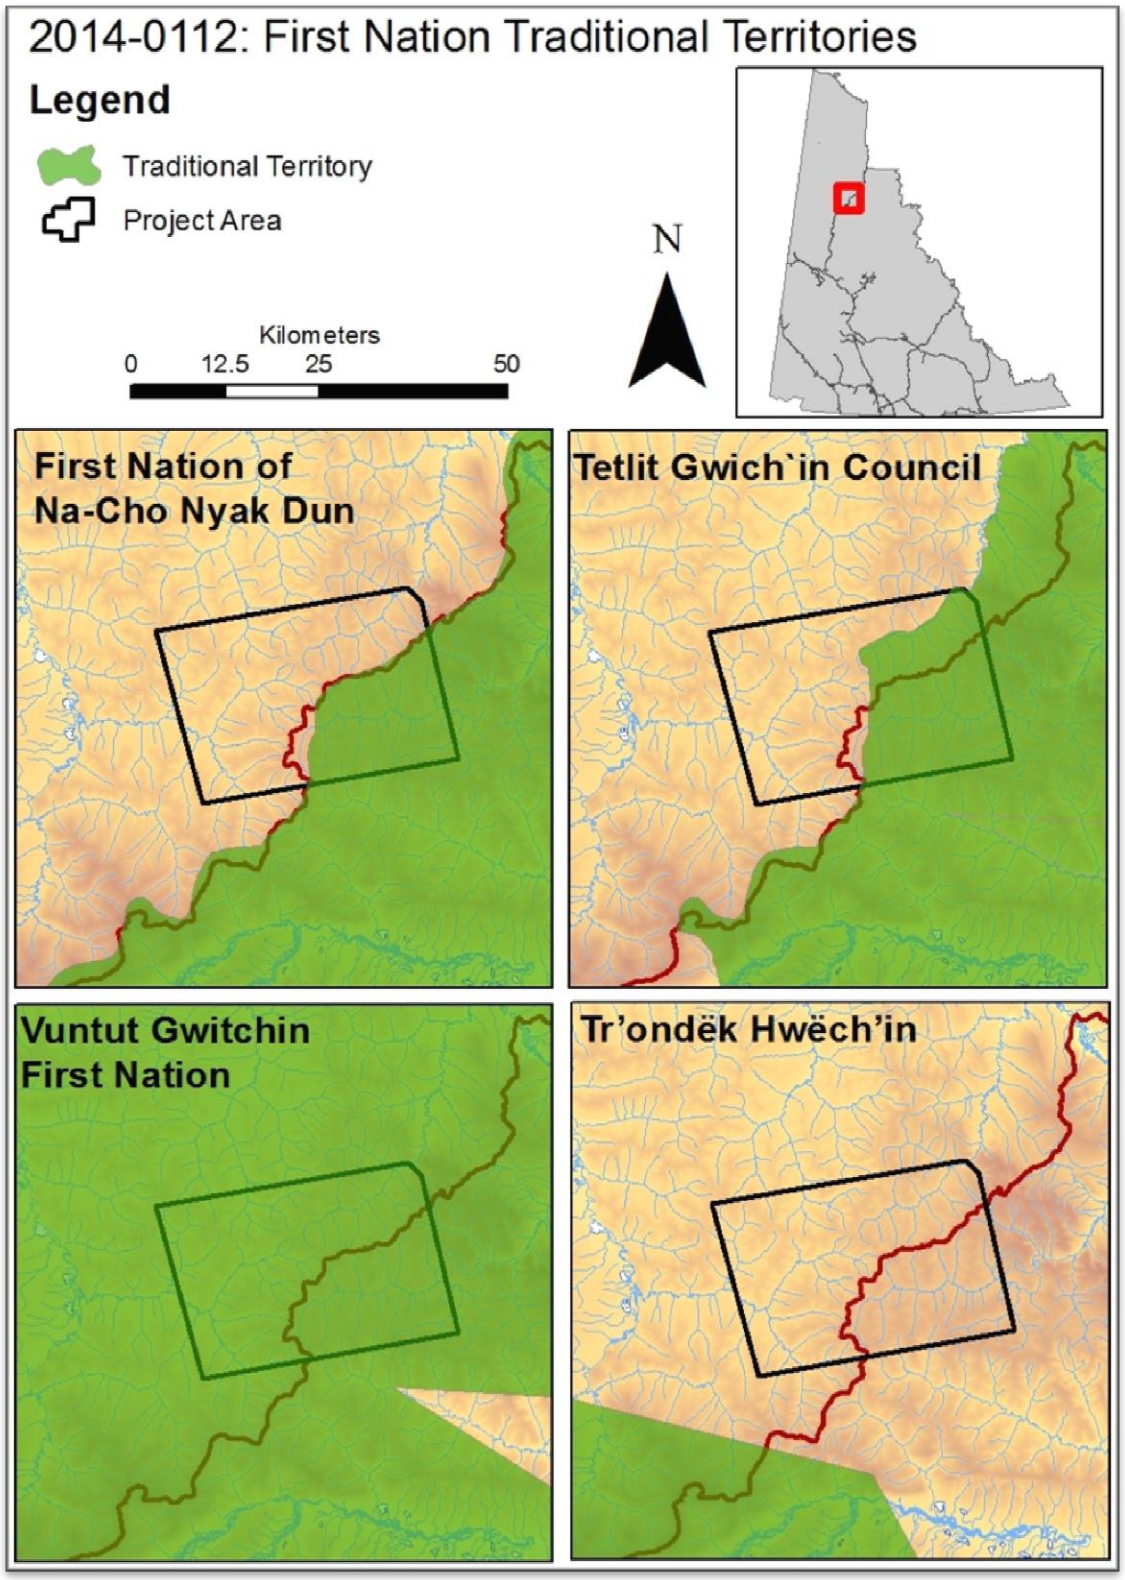

Figure 1: The Project area in relation to traditional territories of FNNND, THFN and VGFN, and the use areas of the TGC. The Dempster Highway is shown bisecting the Project area.

A.2. PROJECT SCOPE OVERVIEW

The Project is to take place over an area within the Eagle Plains basin (i.e. as described above in section A.1.). The Project will occur over a period of up to eight years beginning as soon as possible. This section provides an overview of Project activities included in the scope while the next section (section A.3.) provides additional details on each activity and how it is scoped. Project activities include:

- Development and drilling of twenty wells within the Project area, including:
    - Establishment of drill pads (up to 19 pads)
    - Use of drilling mud
- Testing of Project wells, including:
    - Drill stem tests
    - Acid simulation
    - Extended flow testing, up to two years per well, including:
        - Installation of
            - Standard pumpjacks
            - Christmas tree installation
            - Separators
            - Flare systems
            - Storage tanks
        - Production of a maximum of 4 000 barrels (636 000 L) of crude oil per day during flow testing
- Well suspension and abandonment

Road and Quarry Development

- Quarrying of 1 800 000 m^3 of aggregate for use in Project activities, including:
    - Winter development of 23 quarries
    - Use of approximately 450 000 m^3 of aggregate for well pads
    - Use of approximately 1 350 000 m^3 of aggregate for access road construction
    - Use of explosives
    - Reclamation of borrow sources
- Development of all season access roads up to 87 kilometers in length, including:

- Up to five water crossings and use of culverts

Waste Disposal

- Flaring of gas, up to approximately two million cubic feet per day (57 000 L)
- Use of deep well injection to dispose of produced waters and liquid wastes, up to 381 600 L/day
- Use of a mix-bury-cover sump (70 000 m^2) for disposal of drill cuttings and the solid fragment of drilling mud
- Trucking of waste to appropriate waste disposal facilities using public highways

Water Use

- Use of up to 300 m^3 per day, not exceeding 10 percent of instantaneous flow at extraction points, including:
  - Year round extraction from the Eagle River
  - Seasonal extraction from Glacier Creek

Other Project Facilities

- Use of an established camp
- Use of a mobile drill camp (five to eight people)
- Construction of a central processing facility
- Storage of fuel and produced crude at the central processing facility and camp, including:
  - 151 000 L diesel, 24 000 L propane
  - 3 180 000 L crude oil, 119 000 L produced water

Baseline Data Collection and Environmental Monitoring

- Fisheries sampling at each watercourse crossing
- Surface water, groundwater, and permafrost monitoring/sampling
- Wildlife surveys and monitoring
- Helicopter access to support sampling and monitoring programs

Transportation

- Transport by tanker truck of produced crude oil to a point of export, up to 4 000 barrels per day
- Two flights in/out per week to Project location

A.3. DETAILED SCOPE OF PROJECT ACTIVITIES

The proposal and the Proponent's supporting documents, including documents submitted after the adequacy phase, neither clearly define nor delineate Project activities. While exploration Projects often present a wide range of potential outcomes and configurations, proposal documents are often conflicting and contradictory.

Where conflicting information is present, the Designated Office used the Proponent's maximums as the limits of proposed activities. Incorporating maximums into the Project scope allows potential mitigation of all potential scenarios suggested by proposal documents. This section provides details not only on the Project scope but also how the Designated Office determined the scope of Project activities; however, this section provides details only on those activities that are integral to the effects assessment's outcome.

A.3.1 Well Development and Testing

Timing of Activities

Given that the proposed timeline only tentatively assumes which wells will be drilled during winter and that the timeline cannot be accurate as it assumes a 2015 start date, the Designated Office assumes that any well may be bored in either winter or summer. Proposed timelines assume that the Project should have begun in 2015 and thus are no longer up to date; the Designated Office assumes Project activities will commence as soon as the Proponent receives the required authorizations. Project activities will occur for a period of no more than eight years.

Number and Location of Wells

The Proponent intends on drilling up to 20 wells, though "approximately half of these wells are firm proposals to evaluate prospects [the Proponent] has identified for drilling and the rest are contingent on any of the initial wells discovering crude oil or natural gas" (YOR 2014-0112-073-1, 13). While some Project documents indicate that legacy wells may be used for extended flow tests (YOR 2014-0112-056-1, 2), the proposal's Project description clearly states that the program centers around the drilling and testing of 20 wells (YOR 2014-0112-073-1, 13). Further, all predictions of flows and estimates of gas production are based on the assumption of 20 wells. The Designated Office scoped the number of wells for drilling and extended flow tests as 20 and has not scoped in exploration activities at existing legacy wells.

The proposal provides well locations within the Project area; however, well locations may change as the Project is completed. Modifications to well locations have occurred in previous assessments. The Designated Office has scoped the geographic boundaries within which the wells are to be drilled as equal to the area covered by the recent 3D seismic survey (assessment 2013-0067).

Well Pads

The drilling of up to 20 wells will require the establishment of drill pads 14 400 m^2 in size (120 m x 120 m) at 19 well sites, as one site will use an existing well pad. Well pads will be constructed out of granular material excavated from Project borrow pits. Each pad will require 21 600 m^3 of granular material on average (1.5 m depth); however, in winter, wooden mats may be used as opposed to granular material.

A.3.2 Road and Quarry Development

Quarry Development

The Project requires the development of quarries to construct access roads and well pads. The Proponent identifies 23 quarry locations for borrow material extraction; however, final locations may be different from proposed locations. One well site is already prepared for exploration due to the previous establishment of a drill pad and will not need borrow material. The remaining 19 well sites will require a little over 400 000 m^3 of borrow material.

Borrow material is required principally for road development; however, the proposal is contradictory on borrow requirements for road construction as the total length of road requiring borrow material is unclear. The response to information request one indicates a total Project requirement of approximately 1 800 000 m^3 of borrow and 87 km of road (YOR 2014-0112-036-1, 2). The response to information request three indicates a total Project requirement of approximately 1 700 000 m^3 of borrow and 82 km of road, with no explanation of the change (YOR 2014-0112-056-1, 5). The Designated Office has used the upper estimate, 1 800 000 m^3, in its scoping of the Project.

Road Development

As indicated above, the total length of all-season roads to be constructed is unclear in proposal documents. In the revised Project proposal (YOR 2014-0114-074-1, 85) road segment lengths provided indicate 82 km of access roads while the Proponent's final information submission (YOR 2014-0112-265-1, 1) reaffirms 87 km of access road. While these estimates are quite similar, the Designated Office is using the larger of the two estimates in its scoping. Roads, like well and quarry locations, may have different final alignments than proposed but are scoped as being located within the Project area.

Roads for the initial drilling of wells may be winter roads; however, as the Proponent anticipates that all wells will be selected for extended flow testing "it should be assumed that all the proposed access roads will be upgraded to all-season roads" (YOR 2014-0112-036-1, 1). As such, all roads proposed are assessed as though they will either be constructed as all-season roads or will become all-season roads.

Winter roads would only be constructed in the event of sufficient snow coverage and if water bodies are frozen. All-season roads will require the construction of five water crossings. These crossings will be constructed with culverts.

A.3.3 Flaring

Flaring and Natural Gas Disposal

The Proponent notes that drill stem tests and extended flow tests may require flaring. Drill stem testing will not generate sustained flows of natural gas. The Proponent indicates that flaring is not expected to last longer than a day during these tests. However, for extended flow tests large amounts of natural gas are likely to be generated and flaring may last for extended periods.

The proposal is not clear on flaring requirements. Volumes of flared gas depend on how much gas is contained in recovered fluids. The Proponent provides different sets of predictions:

- 300 cubic feet of gas per barrel extracted: from a single data point from past exploration (YOR 2014-0112-199-1, 11)

- "typically less than" 500 cubic feet of gas per barrel extracted: as described in the revised Project proposal (YOR 2014-0112-073-1, 11).
- "expected" less than 571 cubic feet of gas per barrel extracted: as described in the revised Project proposal (YOR 2014-0112-073-1, 40)

The response to information request four provides an estimate of volumes of flared natural gas using three assumptions. These assumptions are production of 2 000 barrels of oil per day, 300 cubic feet of gas per barrel (as listed above), and the "unlikely scenario that 100% of natural gas is flared and not consumed in the operation" of the Project (YOR 2014-0112-172-1, 12). This scenario results in gas volume of 600 000 cubic feet that would require flaring every day.

Using the higher estimate of gas recovery listed above, 571 cubic feet of gas per barrel, a "likely" maximum production scenario of 4 000 barrels per, as well as an assumption that 100 % of natural gas is flared, the upper limit of gas flaring approaches 2 300 000 cubic feet per day. This assumes that all wells are selected for extended flow testing, which the response to information request four indicates is unlikely; however, the Proponent also assumes that all wells will be selected for extended flow tests.

Excess natural gas production may be reduced by using produced gas for heating or electric power generation on site (though this still results in emissions). The Designated Office is using an upper bounds for flaring volumes of approximately 2 000 000 cubic feet of gas per day.

The Proponent has indicated it is possible that natural gas will be reinjected, though no details on this activity are provided. The storage, processing for sale, or re-injection of natural gas is not included in this Project's scope "as discussed previously, gas would either be used for heating, power generation or as a last resort flared" (YOR 2014-0112-073-1, 12).

The scope of the Project does not include flaring of crude oil.

A.3.4 MBC Sump

The response to information request four definitively states that the mix-bury-cover (MBC) sump will only contain the solid fraction of drilling mud and any drill cuttings.[4] Earlier proposal documents had suggested drilling fluids might be deposited in the MBC; however, the Designated Office is scoping the Project to include an MBC sump that will be filled with only solid waste products. The proposed sump is 70 000 m^2 in size and consists of 800 m^2 cells, one of which will be used at a time.

Drill cuttings and the solid fraction of drilling mud will be disposed of in the MBC sump in accordance with the Alberta Energy Regulator's (AER) Directive 50. Each well may produce up to 300 m^3 of cuttings, totaling 6 000 m^3 over the course of the Project. A further 200 m^3 of drilling mud will also be disposed in the MBC sump. Replacement of the drilling mud will increase volumes of drilling mud requiring disposal. In addition to the described wastes, cement returns (excess cement that flows back to the surface during

[4] The revised proposal indicates that the proposed disposal option for drilling fluids is the MBC sump, "fluid would be added to the drill cutting and then mixed with the required amount of soil in accordance with AER Dir 50" (YOR 2014-0112-074-1, 53). The fourth information request response indicates that disposal of drilling fluids in the MBC sump is possible, "if the drilling fluid and cuttings are not mix-bury-cover suitable, they will be transported …" (YOR 2014-0112-0172-1, 28). However, in a submission after the final public comment period, the Proponent indicates, "only solid material will be disposed of in the MBC sump" (YOR 2014-0112-265-1, 4), this is also confirmed in the revised final information request submission, "Drilling mud, as an untreated liquid phase, will never be disposed of in a MBC sump" (YOR 2014-0112-199-1, 31). The Designated Office scoped the Project according to this most recent commitment, that fluid wastes will not be deposited in the MBC sump.

cementing) will be separated from returning fluid, allowed to cure, broken up, and disposed of in the MBC sump. In accordance with AER Directive 50, materials deposited in the sump are mixed at a ratio of three parts soil to one part waste.

A.3.5 Other Project Facilities

Main Camp

The Proponent established the primary camp for the Project in 2011, during previous activities. The camp is located at km 325 of the Dempster Highway. The camp operates under a municipal water licence and has a capacity of 75 people. The camp also has an authorization for incineration of wastes and storage of fuel. The Proponent does not propose any changes to the operation of the camp. The main camp will house all personnel except for critical frontline supervisors who will be housed at the mobile rig camp.

Mobile Rig Camp

The mobile rig camp is on the drilling rig. This facility will house five to eight personnel who are frontline supervisors such as the geologist, medic, and rig manager.

Drill Rig

The drill rig for the Project is NCY Rig #1. This rig is a 'super single' that can hold a single section of drill pipe in the derrick at a time. The drill rig has a capacity of 2 400 m (YOR 2014-0112-012-1), as such the Project is scoped with a maximum depth of 2 400 m. The drill rig requires a drill pad of 120 m by 120 m.

Service Rig

A service rig may be used by the Proponent to perform completion or work overs for Project wells should the need arise. The service rig would not house any personnel but would be staffed by three to five personnel.

Central Processing Facility

A central processing facility is proposed near the main camp. The central processing facility will "comprise of additional multi-stage and multi-phase separators, heater treaters, [a] vapour and gas collection system, and possibly [a] central power generation facility to power all discrete well batteries" (YOR 2014-0112-073-1, 17). The central processing facility will require storage facilities that allow storage of up to 20 000 barrels of oil (3 180 000 L).[5] Produced water and propane will also be stored to a lesser extent at the central processing facility.

[5] Total storage requirements for produced crude remain unclear. The Proponent states that a ten-day storage requirement is used to base the amount of storage capacity. The conceptual map (YOR 2014-0112-163-1) of the central processing facility show 7 x 750 barrel storage tanks (835 000 L), while the revised proposal notes five tanks and a storage capacity of 20 000 barrels (3 180 000 L) based on production of 2 000 barrels per day (YOR 2014-0112-073-1, 17). Further, the "likely maximum" production of 4 000 L per day with a ten day storage requirement would suggest a volume of 4 000 barrels (6 360 000 L) (YOR 2014-0112-074-1, 64). The Designated Office has scoped the size requirements as 20 000 barrels as this prediction is the most clear and substantive of all storage predictions.

A.3.6 Other Activities

Helicopter Access to Support Baseline Sampling and Monitoring

Helicopter access/support may be used in areas where ground access is limited or non-existent, or may be used to minimize environmental impacts or disturbances that would result from the construction of ground access. Helicopter access will be used by NCY for support activities that may occur only intermittently over time such as during sampling, surveying and monitoring including follow up monitoring.

Transportation of Crude Oil

With a likely maximum production of 4 000 barrels (6 360 000 L) of crude oil per day, transport requirements to the south will have a high likely maximum. The Project proposal is unclear on the volume of tanker traffic south along the Dempster, Klondike and Alaska highways. The revised proposal projects 120 round trips per month carrying produced fluids (YOR 2014-0112-074-1, 130); however, the proposal also indicates that produced liquids would be carried in B-trains with a capacity of about 65 000 L (YOR 2014-0112-074-1, 128). The use of B-trains would require approximately 10 round trips per day, for approximately 300 round trips per month. The Designated Office has scoped the Project to include 10 round trips per day of crude as the maximum amount of transport of crude oil along public highways.

Crude will be transported from Eagle Plains to Skagway via the Dempster Highway, Klondike Highway, and Alaska Highway to the port in Skagway, Alaska. Other possible ports include Haines and Valdez. If this route is not feasible, crude will travel by truck to: Fort Nelson, BC; Fort St. John BC; or Grande Prairie AB.

Transportation of Natural Gas

While the Proponent describes the possibility of shipping surplus natural gas via truck to "industrial consumers or northern communities" the proposal clearly and definitely states that processing gas for sale is outside of the scope of this Project (YOR 2014-0112-073-1, 12).

Other Road Transportation

The Proponent defines and estimates that its normal traffic levels during the winter season will reach about 40 vehicles per day within the Project area. Project activities such as drill mobilization, access road construction and summer mobilization will generate the highest traffic. Mobilizing the drill rig, for example, requires 15 to 20 vehicle loads. Extended flow testing will require the least traffic volume, at about 20 vehicle trips per day. Daily traffic on site will at minimum include eight – nine light-weight service trucks, one water truck and one fuel truck. The proposal also includes the “occasional” transport of drill cuttings from the well sites to the sump location. Onsite traffic will use the Dempster Highway within the Project area.

Fuel and water trucks will travel to the site once per week or as needed.

When a site is decommissioned, materials will be trucked out of the Project area; for example, the decommission plan includes the sale or recycling of removed culverts as roads are decommissioned. The Proponent does not provide estimates of traffic generation for this activity.

Air Transportation

The Project forecasts twice weekly flights to and from the Project camp at km 325 of the Dempster Highway. This airstrip is located on the Dempster Highway and requires use of control vehicles to allow flights to land or take off.

A.4. RELEVANT PROPONENT MITIGATIONS

The following are relevant mitigations proposed by the Proponent to eliminate, reduce or control adverse effects to the PCH that were considered by the Designated Office.

Sources:

- Wildlife Management Plan (YOR 2014-0112 188-1)
- Access Management Plan (YOR 2014-0112-0187-1)
- Project Proposal, Appendix E – Operational Plan Porcupine Caribou and Safety Plan. Plan to Avoid Impact on Harvesting Activities during the Drilling Program and Create (YOR 2014-0112-025-1)
- Project Proposal, Appendix L – Blasting Mitigation Plan for Wildlife (YOR 2015-0114-067-1)
- Project Proposal (YOR 2014-0112-074-1)

Operational Mitigations

- NCY will use existing access (e.g. trails, roads, etc.) for movement of personnel and equipment rather than creating new access where possible.
- Roads will only be wide enough to accommodate equipment required to complete the Project and will include appropriately spaced passing sections for traffic safety.
- Low impact winter roads will be used for exploratory drilling as much as possible to minimize the intensity of physical surface disturbances.
- To the extent possible, sensitive areas will be avoided particularly during important biological seasons. Sensitive areas include: riparian corridors, wetlands, steep slopes, old growth forest, and critical wildlife habitat and permafrost features.
- One drill rig will be active in the area at any time and wells are planned to be developed sequentially. A maximum of two drills will be operational if required to meet seasonal or permitting schedules.
- Activities are planned and scheduled to minimize interactions with wildlife, as practical.
- Movements of the Porcupine Caribou Herd will be monitored and Project activities will be managed as much as possible to avoid disturbance and to minimize potential habitat avoidance that results from human features and activities.
- Windrows, when built, will be constructed with gaps placed periodically

- Snow embankments along access roads will be ploughed back to allow animals easier crossing of roads.

Wildlife Awareness and Training

- NCY will enforce a “no wildlife harassment” policy for employees and contractors. The policy will encompass “no wildlife feeding,” employee education and wildlife avoidance.
- NCY will provide wildlife awareness orientation to staff and service providers.
- A “no firearms” policy will be enforced. Firearms will be banned except as authorized for protection of employee’s safety while in the field.
- NCY employees and their contractors are prohibited from hunting within the program area.
- Aircraft will adhere to best management practices for “Flying in Caribou Country” (Environment Yukon), as permitted by weather and work requirements.
- All NCY employees and their contractors that enter the program area will be mandated to wear brightly colored safety clothing so that they are visible to other personnel, the public, vehicles (both commercial and private), and harvesters.

Access

- Access roads that lead off the Dempster Highway will be gated so only authorized personnel can enter.
- Access roads will be decommissioned using best management practices to reduce the likelihood of the Project providing long-term access for hunters.
- Low impact winter roads will be used for exploratory drilling as much as possible to limit the extent of physical surface disturbance
- Access roads off the Dempster Highway will be controlled (i.e. gated and radio controlled), and use will be restricted to authorized personnel to minimize off-highway access.
- Access points off the Dempster Highway will be limited to the smallest number technically feasible with the goal of minimizing new access off the highway.
- All industrial exploration activities will be kept within the road right-of-ways and well sites.
- All wildlife will have the right-of-way on roads and vehicles will stop when wildlife are encountered to reduce risk of mortality and disturbance. Vehicles will remain stopped and wait for animals to move off roads. If animals have not moved off the road within five minutes then the driver can proceed at 10 km/h.
- Vehicles will be restricted to 50 km/h or less on all Project access roads with the exception of the Dempster Highway.
- Noise will be minimized by ensuring that all exhaust systems have mufflers installed properly and that all machinery is operating as per specifications.

- Dust dispersal will be managed by enforcing reduced speeds and traffic volumes on access roads.

Blasting

- Environmental/wildlife monitors will survey the surrounding area for any sign of focal wildlife species: moose, caribou, and bears. Blasting will be delayed if focal species are found during surveys, and will recommence once focal species are determined to be further than 1 km away from blasting sites.
- Environmental/wildlife monitors will survey the surrounding area for high value habitat features such as dens, raptor nests and mineral licks or wallows. If high value wildlife feature(s) are found, more detailed mitigation plans will be made in consultation with the Regional Biologist/Conservation Officer.
- Use noise reduction measures (e.g., matting) during blasting.
- All wildlife observations made during development and operation of borrows will be documented and submitted to applicable regulatory agencies: Environment Yukon, Vuntut Gwitchin and others.
- Noise reduction measures will be taken if decibel levels are considered disruptive to wildlife.

Problem Wildlife Management

- Regular (daily) garbage management will be undertaken to remove materials (e.g. metals, plastics, grease, food waste), which may be potentially harmful to wildlife.
- Wildlife monitors will document and report wildlife encounters to the Project Supervisor. Actions to deter wildlife will be considered with input from the local Conservation Officer.
- Any animals destroyed because of imminent human safety risk will be immediately reported to the local Conservation Officer and followed up with a detailed investigation by qualified Project staff.

Caribou-specific Mitigations

- When greater than 500 caribou or one collared caribou are known to be within 30 km of active drilling sites. Operation will continue as permitted mitigation actions that will be taken while the condition lasts will include:
    a. Continue to apply general mitigation measures.
    b. Heightened alert for Project staff. NCY holds daily safety meetings for each work shift; included as part of the agenda for these meetings will be notification to all staff that caribou are in the area. General mitigation measures that apply to caribou will be reviewed by all staff at these meetings.
- When 1 collared caribou is known to be within 6 km of active drilling sites. Operation will continue as permitted mitigation actions that will be taken while the condition lasts will include:
    a. Continue to apply general and Level 1 caribou mitigation measures.
    b. Discontinue snow track monitoring to reduce disturbance.
    c. Restrict non-essential activities on Project roads to reduce disturbance.

d. Reduce speed limit to 40 km/h on Project roads to reduce likelihood of collisions with caribou.

e. Plan access road activity to reduce the frequency of disturbance to caribou (e.g., convoy vehicles during shift changes when necessary to reduce disturbance).

f. All non-essential Project activities will be deferred to a later time.

g. Regularly monitor Project infrastructure to ensure that caribou are not blocked from moving through the area or getting caught in infrastructure (e.g. bear fencing in April).

- When 2 or more collared caribou are known to be within 6 km of active drilling sites. Operation will continue as permitted mitigation actions that will be taken while the condition lasts will include:

    a. Continue to apply general and Level 2 caribou mitigation measures.

    b. Reduce speed limit to 30 km/h on Project roads.

    c. No blasting will be permitted.

    d. No new construction will be permitted.

    e. No drill moves will be permitted

    f. Mitigation measures will remain in effect until NCY contacts the Regional Biologist to discuss Project Activity options or the caribou move out of the areas.

Monitoring (General Wildlife Including Caribou)

- Monitoring:

    a. Monitor and verify wildlife uses of the area.

    b. Monitor and evaluate the effectiveness of mitigation measures.

    c. Identify unanticipated Project effects.

    d. Inform adaptive management and additional mitigation measures

- Annual footprint survey using GPS and GIS to measure the area of Project disturbance (i.e. direct habitat loss) is consistent with Project Proposal (assessment) and North Yukon Regional Land use Plan Landscape Disturbance Levels for surface and linear disturbance.

- Monitor by logging vehicle traffic and road use, also reporting any unauthorized road/trail use. This is to ensure traffic volumes are consistent with Project proposal (assessment) and is mitigations are effective.

- Continuous logging of focal species by Project personnel and contractors to document occurrences near Project facilities.

- Record collisions, near misses and all other observed wildlife mortalities within Project area (those involving caribou will be reviewed to determine if further cation is needed).

- Record hunter kills from Project related access.

Caribou-specific Monitoring

- Regional monitoring: request weekly collared caribou distribution maps from the Regional Biologist. NCY will provide the location of active drill sites so accurate buffers can be mapped.

- Level 1 caribou mitigation measures apply when greater than 500 caribou or one collared caribou are known to be within 30 km of an active drill sites. Operation will continue as permitted and mitigation actions that will be taken while the condition lasts will include:

    a. Continue to apply general mitigation measures.

    b. Heightened alert for Project staff. NCY holds daily safety meetings for each work shift; included as part of the agenda for these meetings will be notification to all staff that caribou are in the area. General mitigation measures that apply to caribou will be reviewed by all staff at these meetings to further ensure compliance.

- If Level 2 caribou mitigation measures apply when 1 collared caribou is known to be within 6 km of active drilling sites. Operation will continue as permitted and mitigation measures while the condition lasts will include:

    a. Continue to apply general and Level 1 caribou mitigation measures

    b. Discontinue snow track monitoring to reduce disturbance.

    c. Restrict non-essential activities on Project roads to reduce disturbance.

    d. Reduce speed limit to 40 km/h on Project roads to reduce likelihood of collisions with caribou.

    e. Plan access road activity to reduce the frequency of disturbance to caribou (e.g. convoy vehicles during shift changes when necessary to reduce disturbance).

    f. All non-essential Project activities will be deferred to a later time.

    g. Regularly monitor Project infrastructure to ensure that caribou are not blocked from moving through the area or getting caught in infrastructure (e.g. bear fencing in April).

- Level 3 caribou mitigation measures apply when 2 or more collared caribou are known to be within 6 km of active drilling sites. Operating drills will continue as permitted and mitigation measures while the condition lasts will include:

    a. Continue to apply general and Level 2 caribou mitigation measures.

    b. Reduce speed limit to 30 km/h on Project roads.

    c. No blasting will be permitted.

    d. No new construction will be permitted.

e. No drill moves will be permitted.

f. Mitigation measures will remain in effect until NCY contacts the Regional Biologist to discuss Project activity options or the caribou move out of the areas.

- Regional monitoring: NCY depends on continued collaring for triggering caribou mitigation measures, so will consider supporting the government's long-term population monitoring efforts.

Decommissioning

- Reclaim and decommission all surface disturbances when no longer required.
- The first hundred meters of roads connecting to the Dempster Highway will be made impassable using appropriate methods (e.g. rock fencing and ditches).
- Where vegetation has not reoccupied all-season roads at closure NCY will scarify the roadbed to promote water infiltration and vegetation establishment.
- Where possible stockpiled organic material from road construction and slash debris will be spread across the old roadway to promote re-vegetation. When this is not possible, roadway sections will be seeded using native grass seed mixes.
- At creek crossings, culverts will be removed and flow channels will be re-established.

Reporting

- NCY will provide weekly and annual reports; these reports will be submitted to: Vuntut Gwitchin First Nation's manager of Natural Resources, Nacho Nyäk Dun First Nation's manager of Lands and Resources, and Government of Yukon manager of the Oil and Gas Branch.
- **Weekly** - summary reports on wildlife monitoring activities including:

    a. Application of wildlife mitigation measures.

    b. Implementation of wildlife monitoring activities (e.g., snow track survey).

    c. Incidental wildlife sightings.

    d. Project-related wildlife incidents and near misses.

    e. Project-related wildlife mortalities within the Project area.

- **Annually** - Project mitigation and monitoring activities which will generally include the following key pieces of information:

    a. Summary of annual Project activities.

    b. Description of updates to environmental baseline information.

    c. A review of annual monitoring results.

    d. Proposed changes to mitigation measures and monitoring actions, if necessary.

Appendix B BASELINE INFORMATION RELATED TO ACCESS TO AND USE OF THE PORCUPINE CARIBOU HERD

B.1. Overview

A number of First Nation and Inuvialuit communities rely on access to and use of the PCH. The Project area is within the FNNND and VGFN Traditional Territories and the TGC Secondary Use Area. The Project is adjacent to the Tr'ondëk Hwëch'in First Nation (THFN) Traditional Territory. The Dempster Highway begins in the THFN Traditional Territory, therefore, road access to the Project location will cross through THFN's Traditional Territory. The PCH are equally culturally significant and highly valued by the Gwich'in Tribal Council (GTC) and the Inuvialuit.

Baseline information for access to and use of the PCH is critical for determining whether this Project will have, or is likely to have, significant adverse effects to that access and use. A reasonable amount of baseline is required in order to understand the pre-development conditions. An understanding of pre-development conditions is the basis for predicting the level of change expected due to the implementation of Project activities and any associated accidents and malfunctions. Predicting the level of change from baseline conditions (i.e. magnitude), the amount of time effects to baseline occur (i.e. duration), how long it takes to return to normal (i.e. reversibility) and the acceptability of change (i.e. context) are key factors in determining whether effects are adverse, significant and likely.

The following sections summarize baseline information related to access to and use of the PCH that was gathered by the Proponent and by the Designated Office.

B.2. Baseline Information Gathered by the Proponent

The Proponent was requested to contact affected First Nations to determine their current and traditional use of the Project area (YOR 2014-0112-138-1). Requested information included:

- the current use of the Project area including timing and duration;
- the cultural and economic significance of current uses;
- the effects of the Project on current uses; and
- possible mitigations for effects to current uses.

The Proponent's response (YOR 2014-0112-199-1) provided a cursory level of detail. For example:

- General notes that meetings had taken place with the VGFN and that the First Nation had provided comments to YESAB about their traditional land use.
- A summary list of communications with FNNND.
- A summary of communication with the TGC and GTC and that the GTC had provided comments to YESAB.
- General information about subsistence hunting and trapping in the Project area.
- Noting that "hunting, fishing and trapping are very important activities for the Gwich'in culture".

- General list of potential effects and the statement that "Traditional uses of the area will be able to continue outside of the footprint of the Project and hunting with firearms can continue within the bounds identified in the Yukon Hunting Regulations."

In turning its attention to the matters to be considered (s.42 of YESAA) and concluding the assessment (s.58 of YESAA) the Designated Office has concluded that the Proponents response is lacking in substance. The GTC supports this conclusion in stating that the proposal "does not adequately capture the extent of current land use within the Secondary Use Area, nor does it provide adequate information on the use of the PCH." (YOR 2014-0112-127-1) The GTC feel the Proponent has not demonstrated any consideration of whether they have important harvesting areas in or near the proposed Project area.

B.3. Baseline Information Gathered by the Designated Office

The Designated Office compiled the following information to better understand the value First Nations and the Inuvialuit have for accessing and using the PCH.

B.3.1 Cultural Importance of the PCH

The importance of the PCH extends beyond ecological valuation as they are an intimate part of the culture, health and wellbeing of numerous First Nation, Inuvialuit, aboriginal and other communities. The Porcupine Caribou Management Agreement (1985) recognizes Porcupine Caribou as a “value” to Canada generally and that “a special relationship exists between native users and these caribou.” During the Northern Yukon land use planning process, the PCH was deemed "the most important and valued ecological and socio-cultural resource" in north Yukon (North Yukon Planning Commission, 2009). The plan in fact provides the following statement in relation to the PCH:

> "In North Yukon, the Porcupine Caribou hold a special place in Gwich’in culture and life. It has been said that the Gwich’in and the Caribou hold a piece of each other’s heart. The Creator gave the Gwich’in the Caribou to feed and sustain the people, and to keep the teachings and responsibilities to our past, current and future generations alive."

The continuing health of the PCH is of critical importance to the health and well-being of communities in the herd's range. Continuing the traditions associated with access to a healthy PCH is critical for the well-being of communities in the herd’s range. First Nations continue to use the PCH for shelter, clothing and tool making. Teaching traditional practices and ways of utilizing and respecting caribou is an integral part of the health, traditions, culture, lifestyle and economy of First Nations. This socio-cultural connection between First Nations and the PCH is part of the intergenerational transfer of knowledge when families spend time on the land, hunting, fishing and trapping. The importance of the PCH to the culture, lifestyle and identity of First Nation and Inuvialuit people cannot be overstated - it is fundamental to understanding the significance of effects posed by this Project.

B.3.2 Cultural Importance of the Project Area

According to the VGFN, there may be culturally significant areas within the Project area, which include routes, harvesting areas, camps and places of legend. First Nation people such as the VGFN and TGC have used the area over millennia for cultural, subsistence and traditional pursuits. Several areas within the area of the Project have cultural values based on wildlife values, topographical features, proximity to waterways, and logical stopping points along travel routes.

The VGFN related the following traditional uses and/or cultural significance of this area:

- Connection to Dagoo ancestral homeland
- Long-ago physical evidence of Gwich'in ancestors
- Cultural preservation
- VGFN unique sense of place and relationship with the land
- Subsistence reliance on wild food sources
- Trapping

Figure 2 is an excerpt from a heritage and traditional land use map produced by the North Yukon Planning Commission (2006). The areas identified on the map do no overlap with the Project but are in proximity to the general area. Orange polygons represent areas that are culturally significant and/or for community land use by the VGFN. Also demarcated on the map are the following First Nation Settlement Lands:

- VGFN – R-06A, R-08A and R-09A
- THFN – R-49A

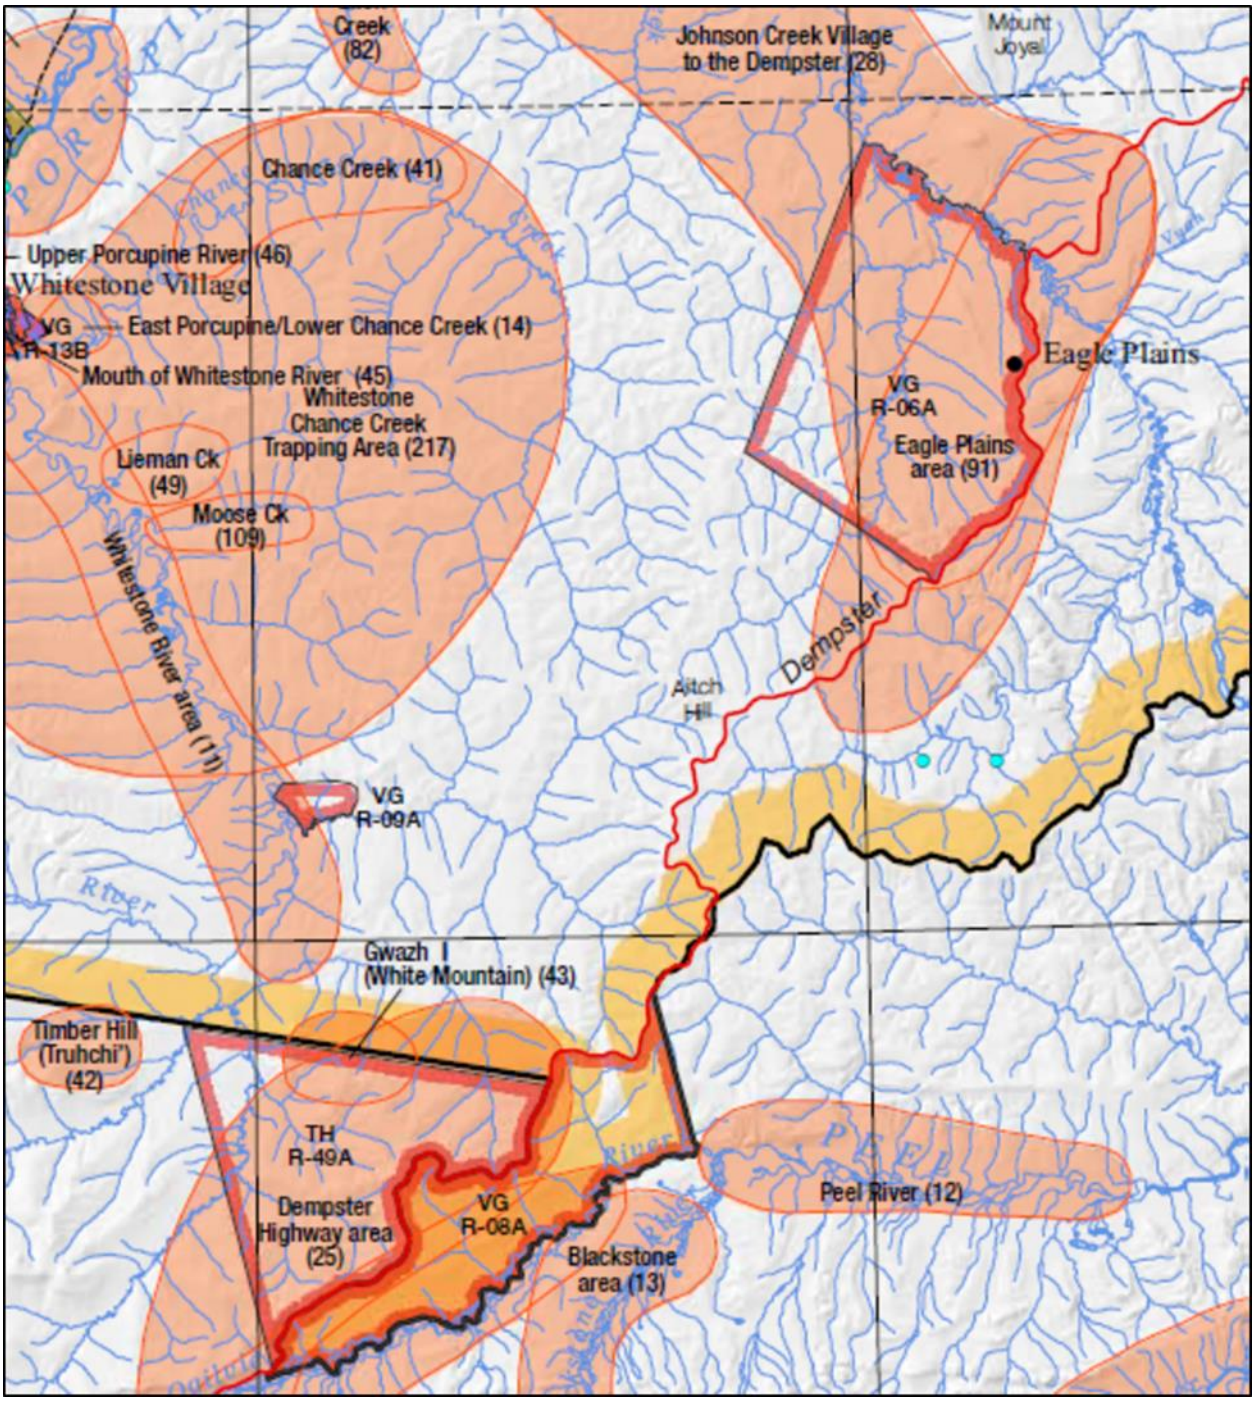

Figure 2: Excerpt from the heritage values and traditional land use resource assessment map

B.3.3 Harvesting

The PCH is a significant food source for northern communities in Alaska, Yukon and NWT. The herd is a major source of subsistence for five major aboriginal harvesters of the PCH in Canada (i.e. Inuvialuit, FNNND, TGC, THFN and VGFN).

Beneficiaries of a Yukon First Nation have the right to hunt for food within the Traditional Territory of his/her own First Nation. For example, a VGFN beneficiary can hunt for caribou or moose within the VGFN traditional territory. These individuals can also harvest male or female caribou and moose, at any time of the year and without a bag limit. Beneficiaries of the TGC (i.e. GTC transboundary agreement) may also harvest Porcupine Caribou anywhere along the Dempster Highway except on Yukon First Nation Settlement Land without that First Nation Government's permission.

The Gwich'in Renewable Resources Board notes that the PCH is the most important traditional food resource for subsistence harvesters in the Gwich'in Settlement Area (Benn 2001). During the 2013 assessment for NCY's Seismic Program, the PCMB noted that the status of the PCH affects First Nation communities and suggested that when the herd suffers that the First Nation and Inuvialuit communities suffer too as they have used the caribou for centuries.

The THFN describe for the Designated Office that the presence of caribou on the landscape is fundamental to the First Nations communities, including the THFN, who have sustained themselves for millennia within this region. The PCH is notably the most important food source of traditional foods for First Nations of the area. There is a deep spiritual connection between THFN subsistence harvesters and the land. Reliance on caribou resources ensure healthy food sources, cultural integrity of harvest and continued access to the guaranteed harvesting rights by the THFN Final Agreement and under the Porcupine Caribou Management Agreement (1985). Therefore, the PCH and associated harvesting rights are a central concern for the THFN (YOR 2014-0112-265-1).

Similarly, the VGFN explain that Old Crow maintains a mixed economy with subsistence harvest of wild foods constituting a valuable part of the economy, alongside wage-based earnings. Subsistence harvest of caribou, moose and fish help offset the high cost of food in the community (YOR 2014-0112-250-1). The PCH is of special cultural significance to Old Crow as this community relies heavily on the herd for subsistence where approximately 600 caribou are harvested each year (North Yukon Planning Commission, 2009). As previously described, Old Crow is the only Yukon Community that cannot be reached by road - it is a fly in community. The population of Old Crow is less than 300 (i.e. according to census data, in June 2015 the population was 258). Based on the understanding that 473 caribou were harvested in 2013/14, the consumption of caribou was 1.6 per capita and up to 2 per capita based on older figures. Surveys results from the 1990s found households serving caribou on average 240 times per year; and traditional foods were reported twice daily in Old Crow diets (Wein, 1995).

The North Yukon RRC notes that: "some of the traditional hunting, trapping fish and wildlife areas down river and around the development to occur, have been VGFN harvesting areas for thousands of year and continue to provide for many families today and will be trusted upon tomorrow" (YOR 2014-0112-139-1).

Additionally, the PCH provides food and economic benefits for others in Yukon through licensed harvesting as well as in Alaska.

B.3.4 Harvest Data

According to information on the PCMB website, based on reported data the total average annual harvest of Porcupine Caribou was 2 571 from 1979 to 2006. Data retrieved for 2013/14 calculated a total estimated harvest by Canadian users of 2 920. The following table (Table 3) presents this information:

Table 3: Total estimated annual harvest, 1979 - 2006 and 2013/14

	1979 - 2006		2013/14	
NWT Gwich'in	1 157	45%	1 936	66%
Inuvialuit	514	20%	368	12.6%
YFN	334	13%	478 (473 VGFN)	16%
AK Native	309	12%	n/a	n/a
YT Resident	154	6%	49	1.7%
AK Resident	77	3%	n/a	n/a
YT Non-resident	26	1%	n/a	n/a
NWT residents	n/a	< 1%	n/a	n/a
	2 571		2 920	

B.3.5 Harvest Timeline

Data collected by the PCMB from 2011 - 2013 indicates that harvesting of PCH occurs throughout the year (Figure 3 and Figure 4). Generally, the majority of harvest takes place from July to October. Minimal harvesting occurs from November to June - however, data from 2012 indicated moderate harvest levels from March to June.

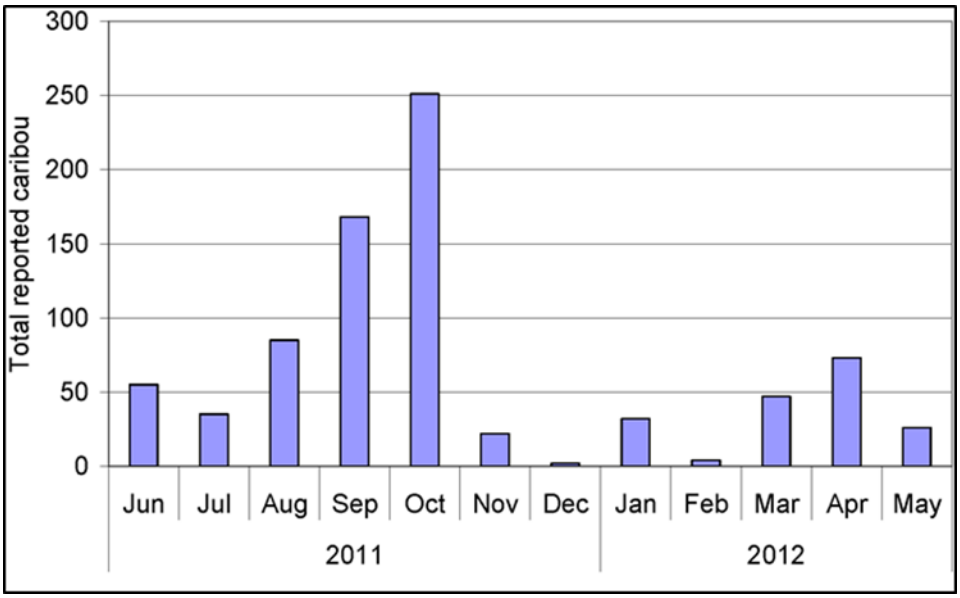

Figure 3: Month of reported Porcupine Caribou harvest, June 2011 to May 2012

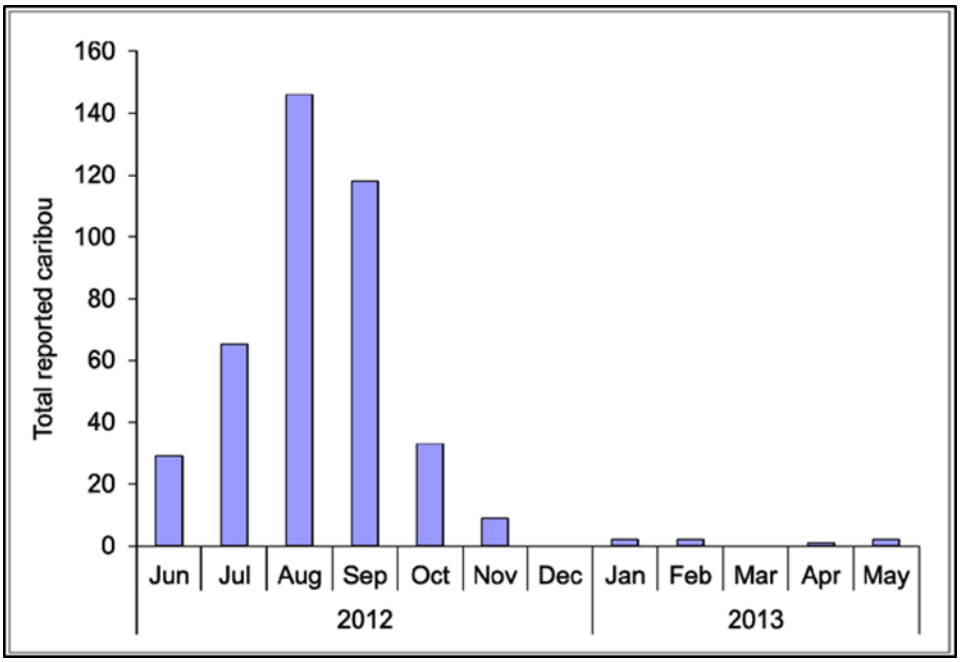

Figure 4: Month of reported Porcupine Caribou harvest, June 2012 to May 2013

B.3.6 Harvest Locations

Data collected by the PCMB from 2011 - 2013 indicates that harvesting of PCH occurs adjacent the Dempster Highway, in proximity to Old Crow and along the northern coast (Figure 5 and Figure 6). Highest densities were observed on either side of the Yukon-NWT border and along the northern coastline. This data is not a complete picture of the harvest since in both years an average of 594 caribou harvests occurred in unknown locations. Further, this data only captures reported harvest.

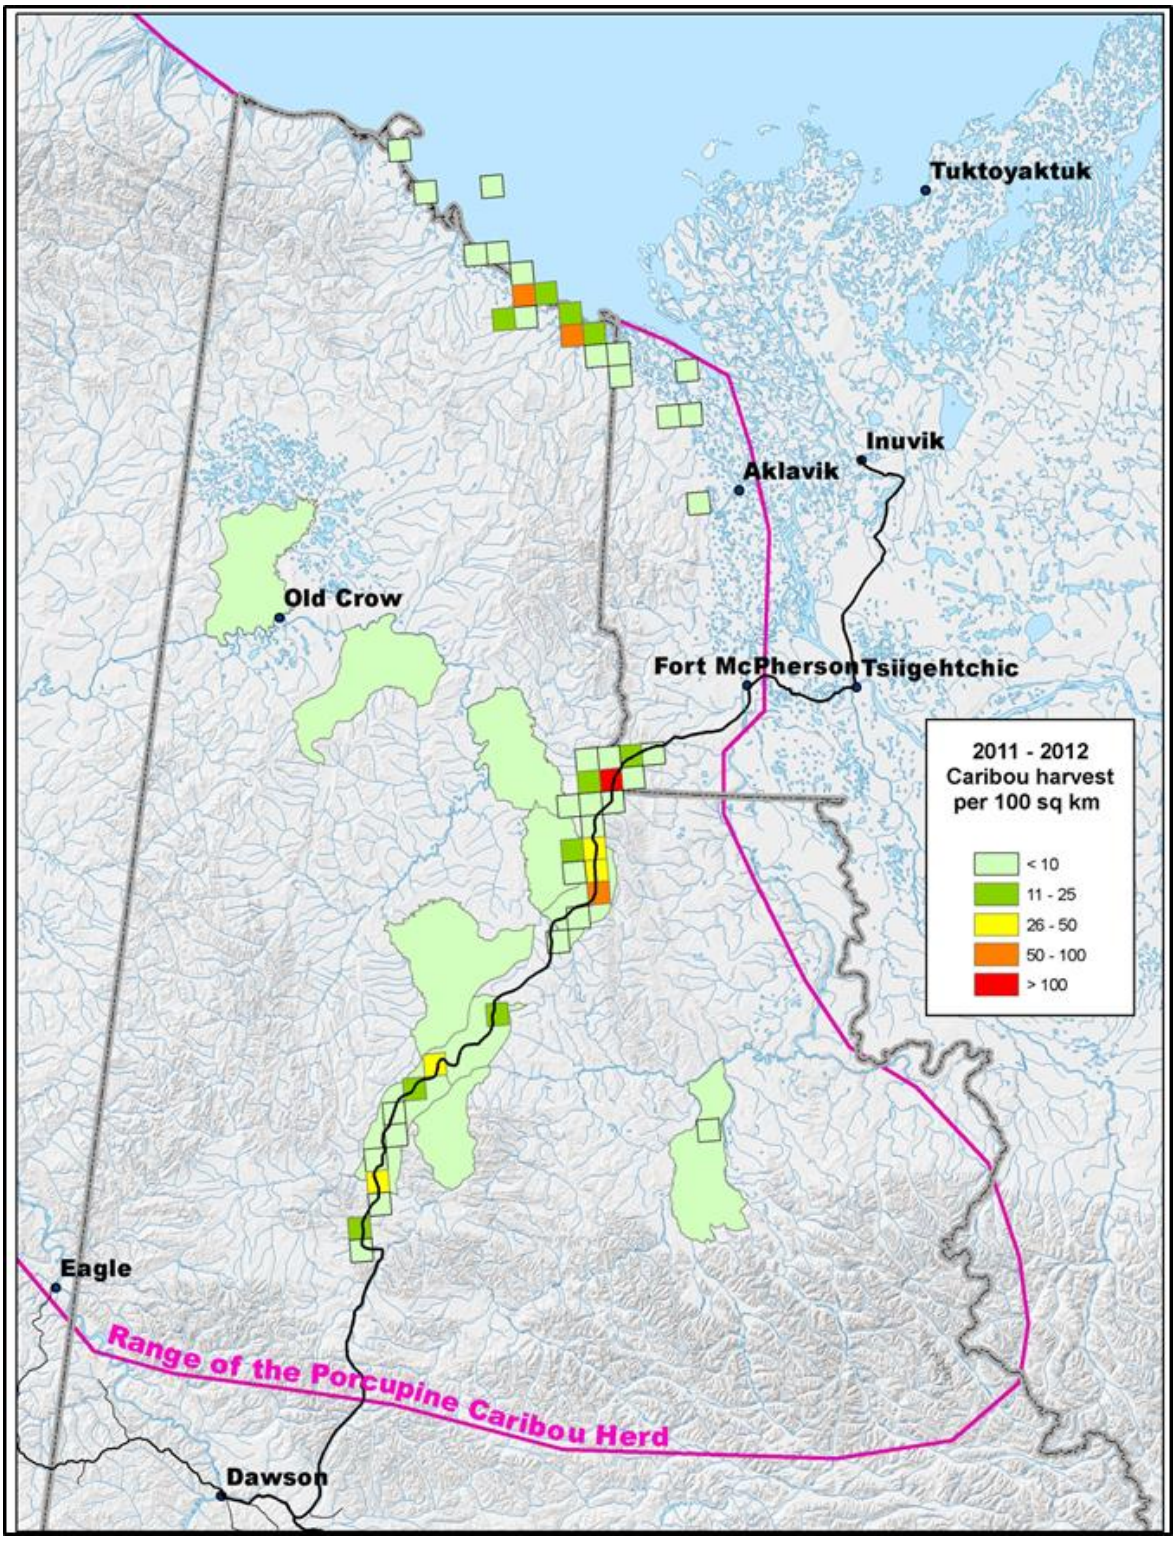

Figure 5: Density of reported Porcupine Caribou harvest 2011 – 2012 (not including 576 caribou of unknown location)

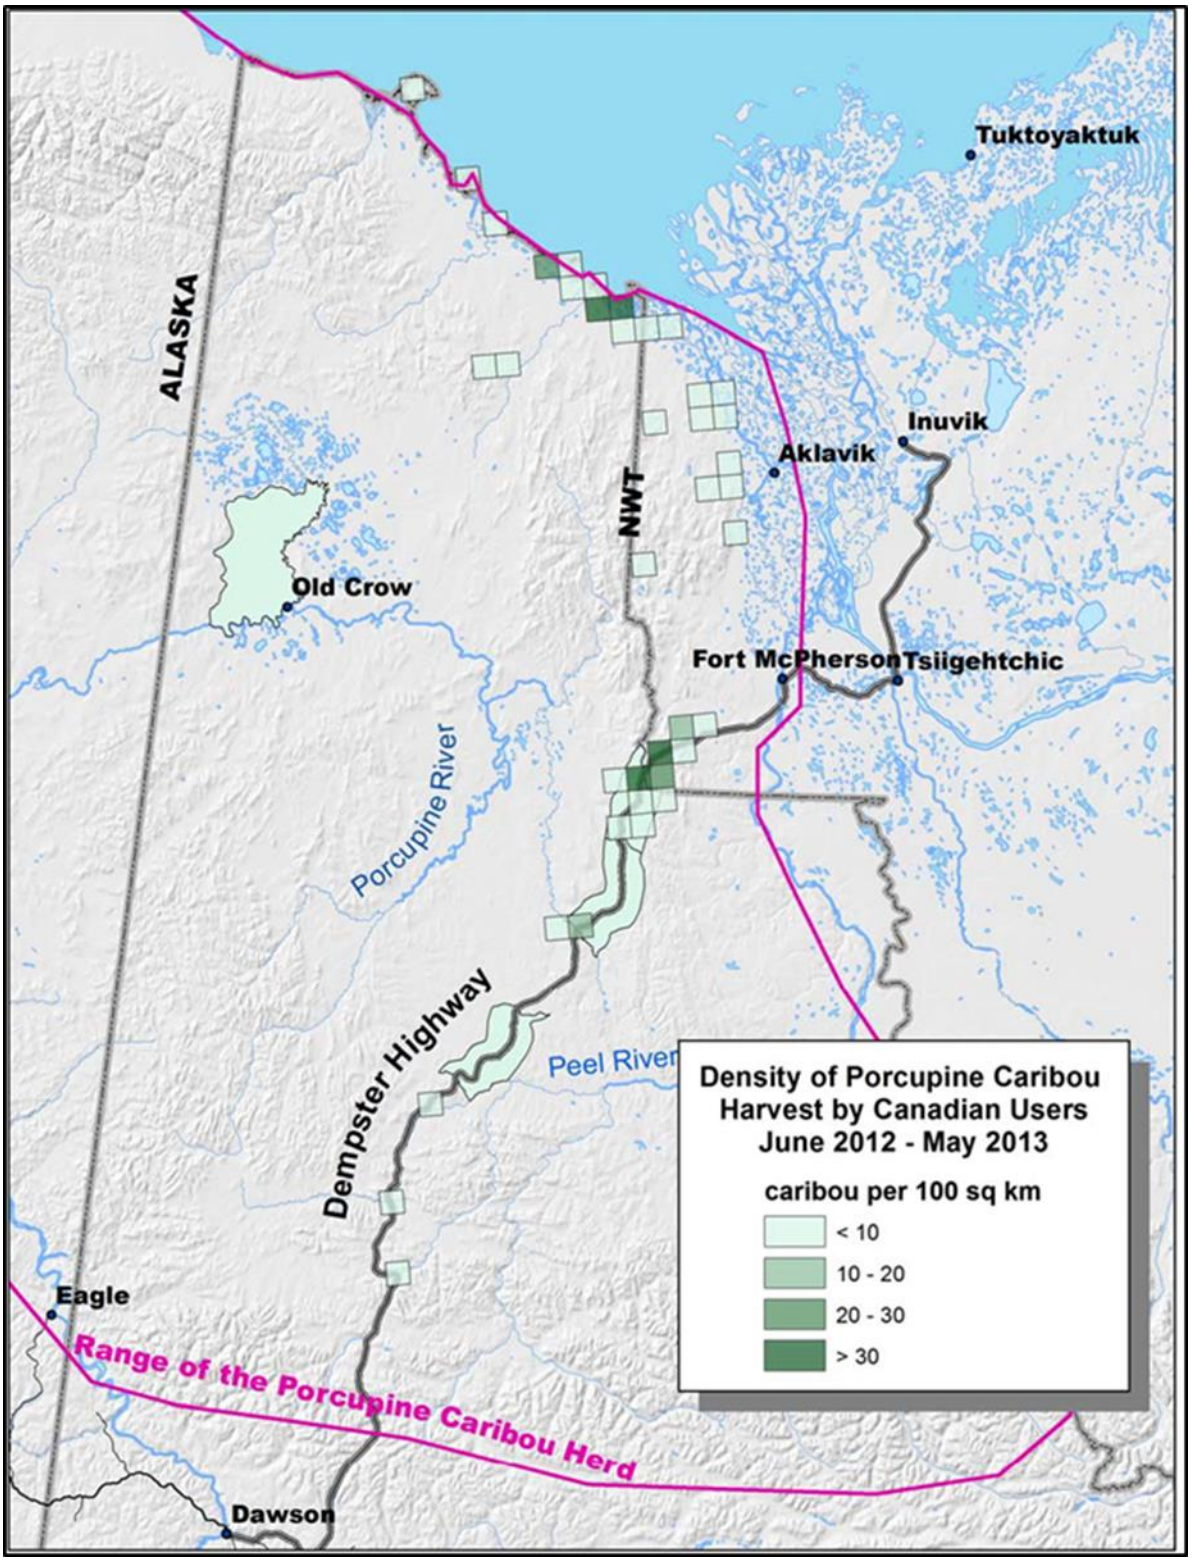

Figure 6: Density of reported Porcupine Caribou harvest 2012 - 2013 (not including 612 caribou of unknown location)

B.3.7 Harvest Success

The PCMB (YOR 2014-0112-133-1) provided the following information relating the level of harvesting in and around the Project area:

> "During the 2013-14 3D seismic program, harvest did occur throughout the length of the winter within proximity to the project and likely totaled in the thousands of caribou (please note this number will be better identified during the PCMB's Annual Harvest Meeting in February 2015). Based on reports and firsthand observations, harvest in the seismic area did not intensify until April when significant harvest did occur in the project area. In winters when Porcupine Caribou numbers are high in this area but not readily available elsewhere, it can be expected that harvest could number into the hundreds or even the thousands in the project area. We also note that the presence of all-season roads would negate the seasonality of the program, making it year-round, thus potentially extending the timing of impacts. NCY suggests that "[i]n the event the ability to harvest is impacted by the proposed Project, FN have the potential to hunt elsewhere, or at another time." The PCMB is very concerned about this statement, in light of the points noted above. As indicated, harvesters need to be able to hunt when and where caribou are available — including the project area — as it is their right to do so when conservation is not a concern."

The PCMB also issues an Annual Summary Report which includes a traditional knowledge section. The 2015 report presented information on whether hunters met their needs for caribou in the year of the report. The dataset is from 2000/01 to 2014/15 and relies on interview responses - Figure 7**Error! Reference source not found.** displays this data.

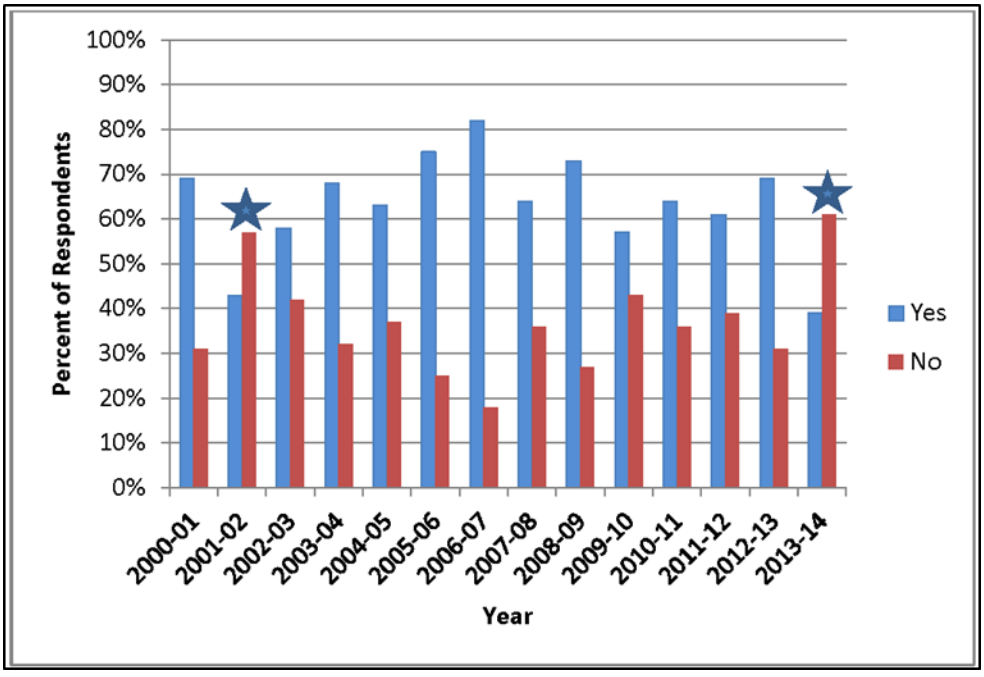

Figure 7: Percentage of respondents that met their needs for caribou from 1996-97 to 2013-14. Stars indicate years that are significantly different than other years.

For 2014/15 the conclusion was that the majority of respondents (61%) did not meet their needs for caribou in 2013-14. This represents the first year since 2001-02 where hunters that were interviewed did

not meet their needs for caribou. This result is significantly different than all years with the exception of 2001-2002. Two reasons are provided: first, 33% of respondents did not go hunting because they bought reindeer, had no transportation, or the caribou were late or too far; second, of the 67% of respondents that did go hunting, they were not successful due to:

- A lack of transportation.
- Low availability in hunting area or changes to traditional migration routes of caribou.
- Purchase of commercial reindeer meat.
- Low water for boating.
- Poor health or advanced age of hunter.

The conclusion of this section of the annual report is that there are many factors affecting the ability of hunters to meet their needs including changing distributions, caribou migration routes and social factors.

B.3.8 Observations on PCH Abundance

The traditional knowledge section of the PCMB's 2015 annual report also presented information on the abundance of PCH over the previous year. According to the findings, out of 63 respondents:

- 46% reported seeing fewer caribou that previous years.
- 27% commented that caribou had changed their migration route.
- 21% commented that the caribou were not in their area.

Appendix C BASELINE INFORMATION RELATED TO THE PORCUPINE CARIBOU HERD

The Designated Office utilized the following maps and tables to better understand the baseline conditions for the PCH range, seasonal distribution, migration, and occupancy. Figure 8 and Figure 9 provide a visual for the PCH range and migratory routes.

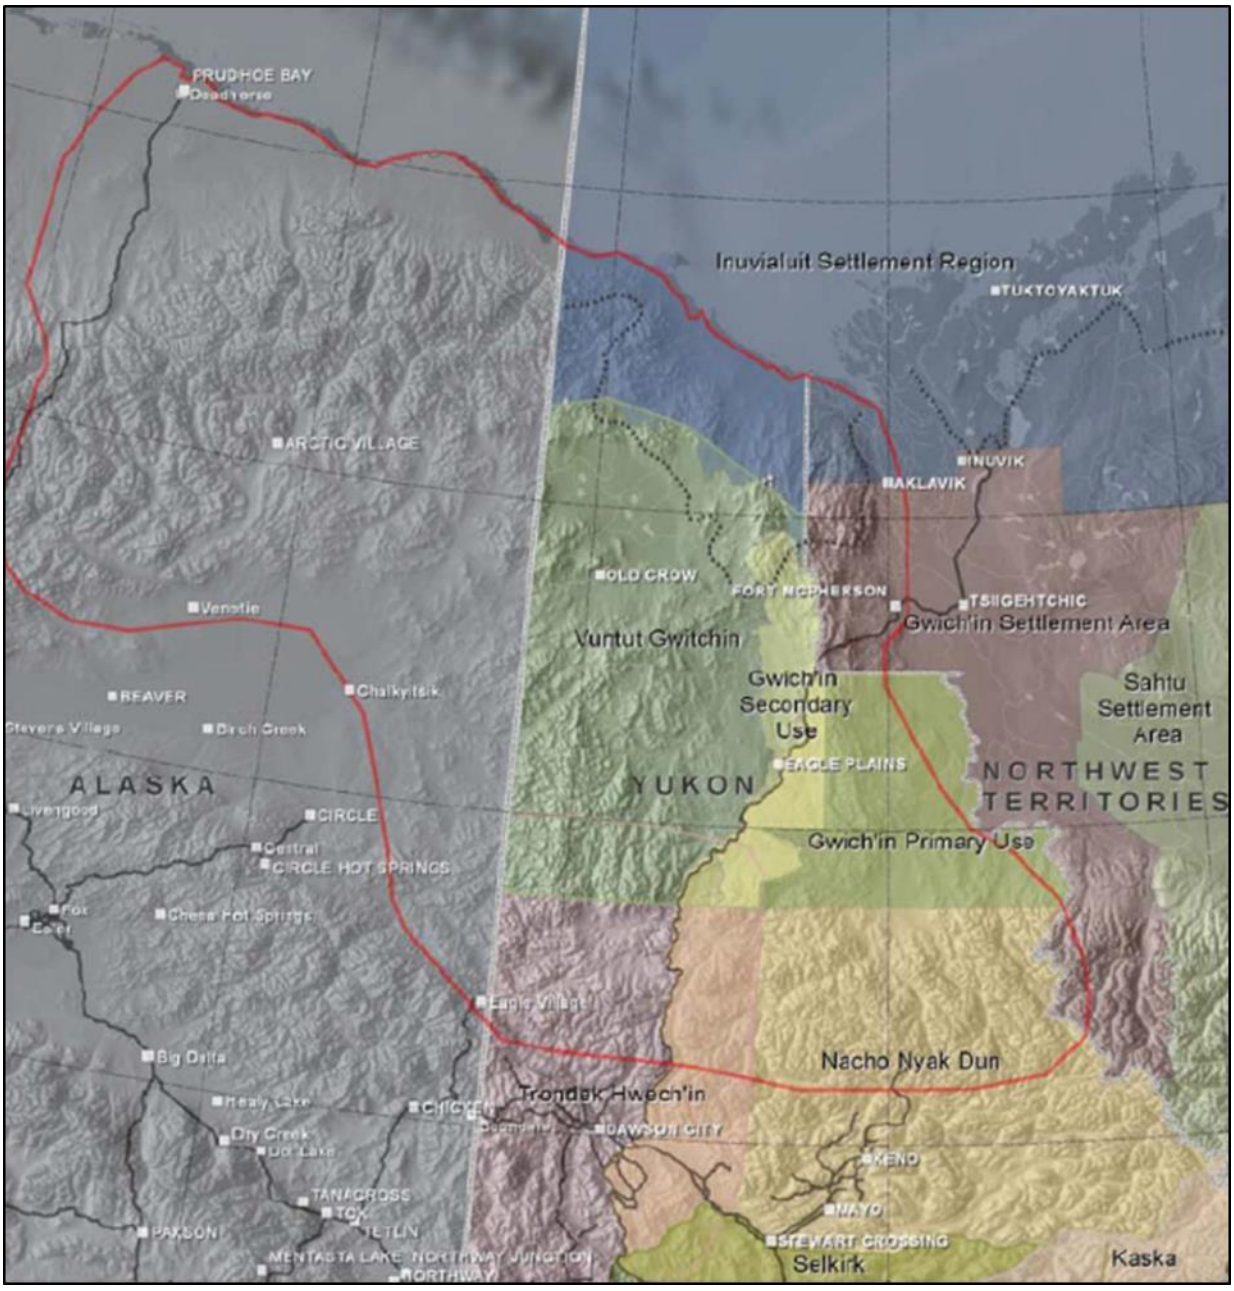

Figure 8: Porcupine Caribou Herd range (Government of Yukon, 2016)

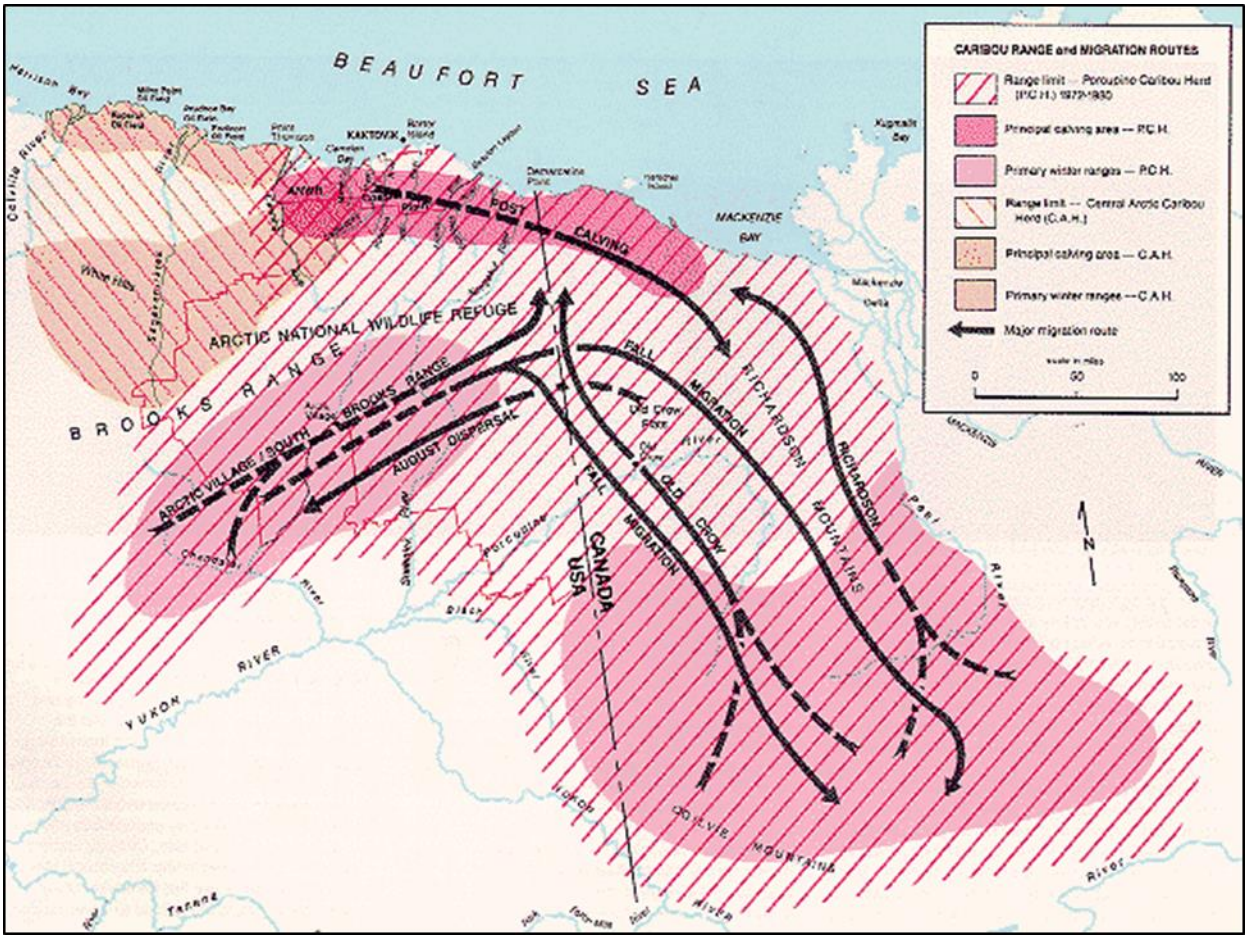

Figure 9: Migration routes of the Porcupine Caribou Herd (Caribou in the Arctic Refuge, 1994)

The PCMB provided satellite collar imagery demonstrating overlap between PCH and the Project area from October 18 - December 11, 2015 (YOR 2014-0112-223-1). **Error! Reference source not found.**Figure 10 is a clear indication of the overlap – it's important to note that the data points observed reflect the presence of caribou with satellite collars, meaning there could in fact be many more caribou present that do not have collars.

As noted by the PCMB, "Movements in November of this year [2015] likely represented 50,000+ caribou migrating directly through the Project area with many tens of thousands immediately adjacent, for a total of >100,000 caribou." And further, the PCMB state: "Movements this year typify what can be expected in the future, although it is impossible to anticipate the frequency which could range from many consecutive years to more sporadic occupation of the area. It is clear that we can anticipate a wide range of use of the Project area from tens of thousands to small or no groups of caribou in a given year, and the period may vary from days to all winter. Therefore, detection of groups in the Project area prior to new activities is key to successful mitigation." This information is demonstrative of why the Designated Office is unable to determine how the herd might respond to the Project, and this in turn makes predictions on probable effects impossible.

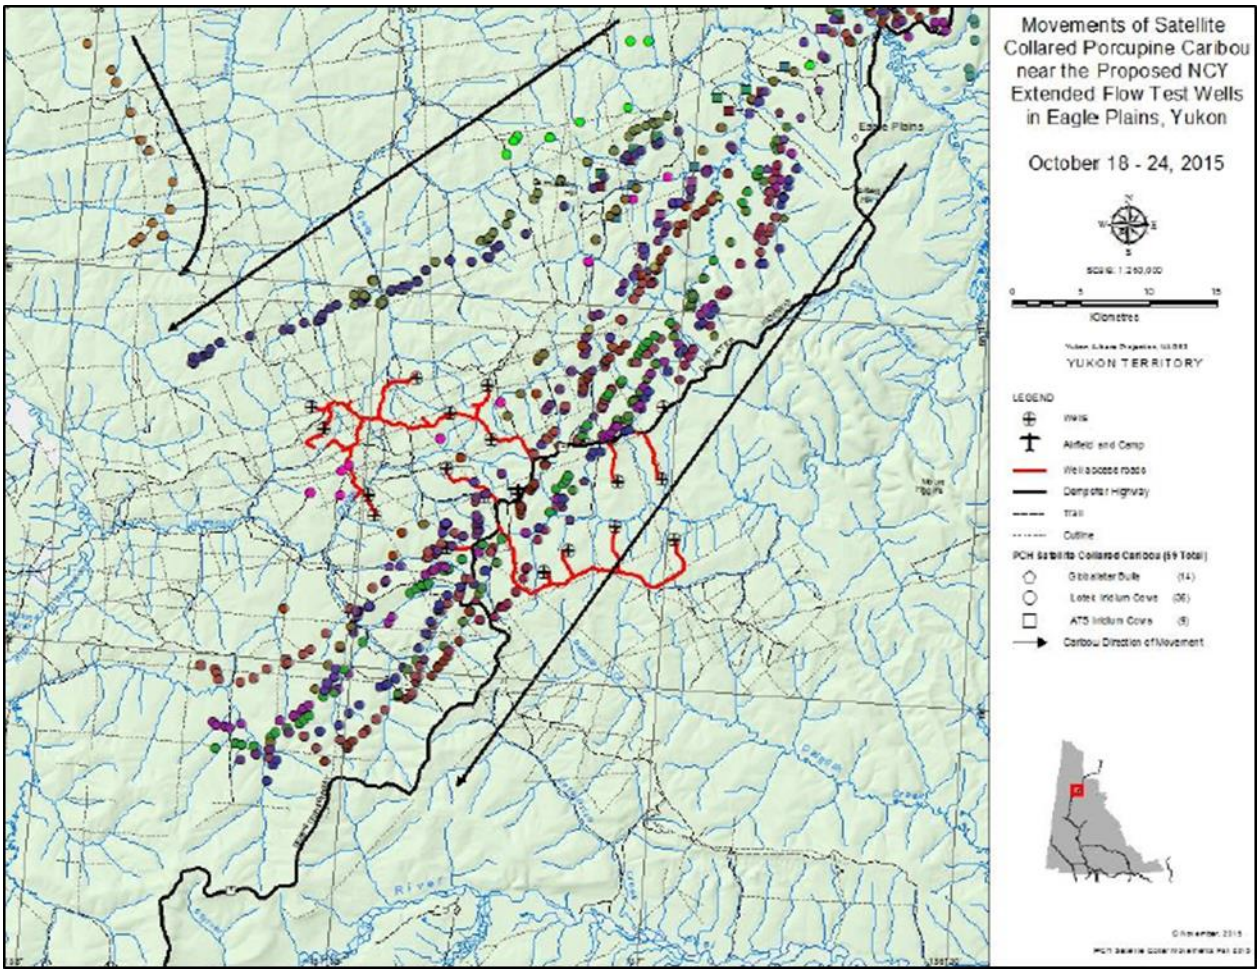

Figure 10: Location and movement of collared Porcupine Caribou in vicinity to the Project area (YOR 2014-0112-223-1)

Ryder et.al. (2006) produced an integrated assessment of the PCH that describes their seasonal distribution, movements and habitat preferences. The study considered both local knowledge and habitat suitability mapping. The following two maps (Figure 11 and Figure 12Figure 12) help to demonstrate the general overlap between the PCH and the Project during the fall, winter and spring migration and over-wintering. These maps provide a bigger picture view of the PCH patterns of movement and range use and complement the Project-specific satellite collar imagery provided by the PCMB.

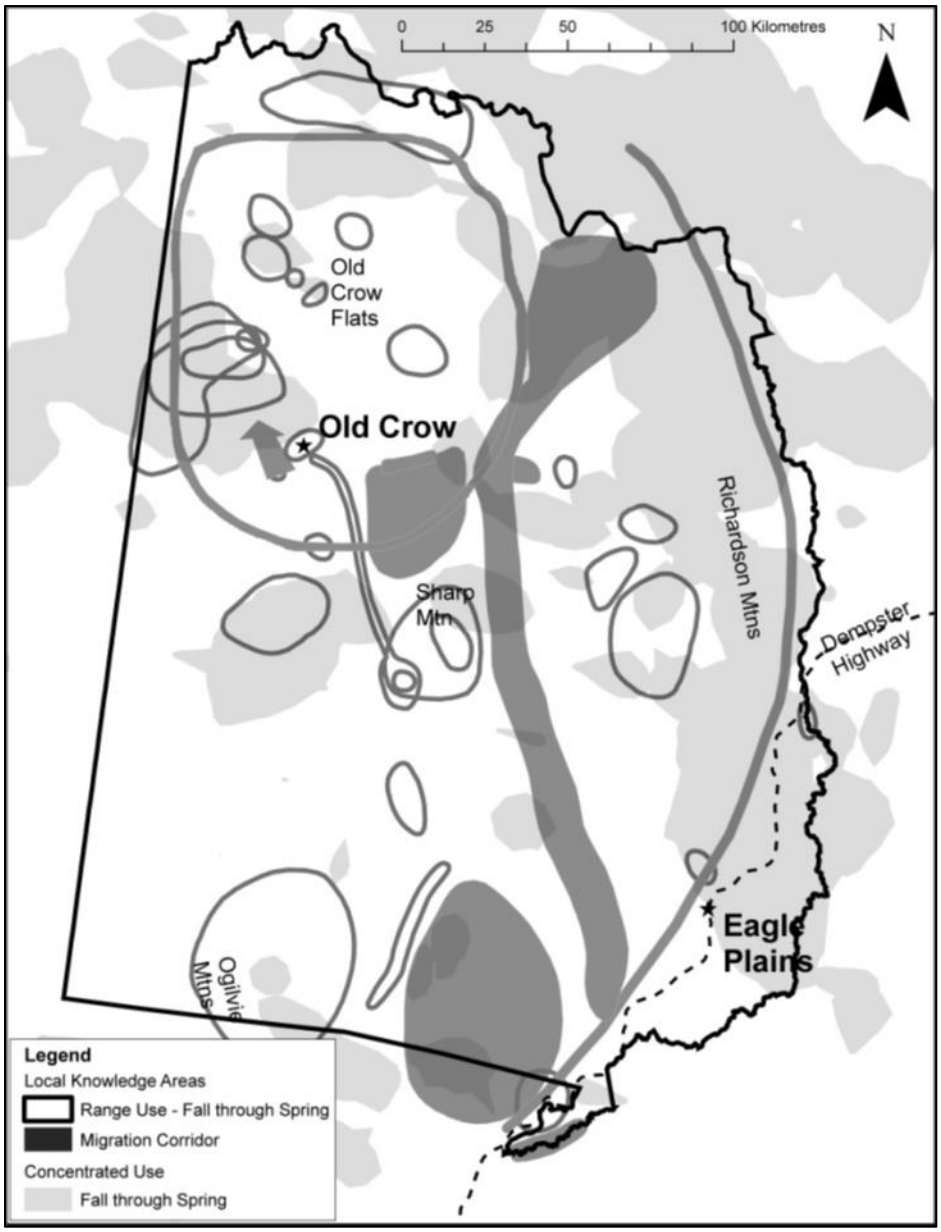

Figure 11: Overlay of local knowledge and concentrated use areas for fall, winter and spring migration seasons. Important caribou range areas within the North Yukon Planning Region from August to May, as indicated by Old Crow residents, are shown as polygons (dark grey outline). Migration corridors (dark grey shading) and concentrated use areas (light grey shading) are also shown.

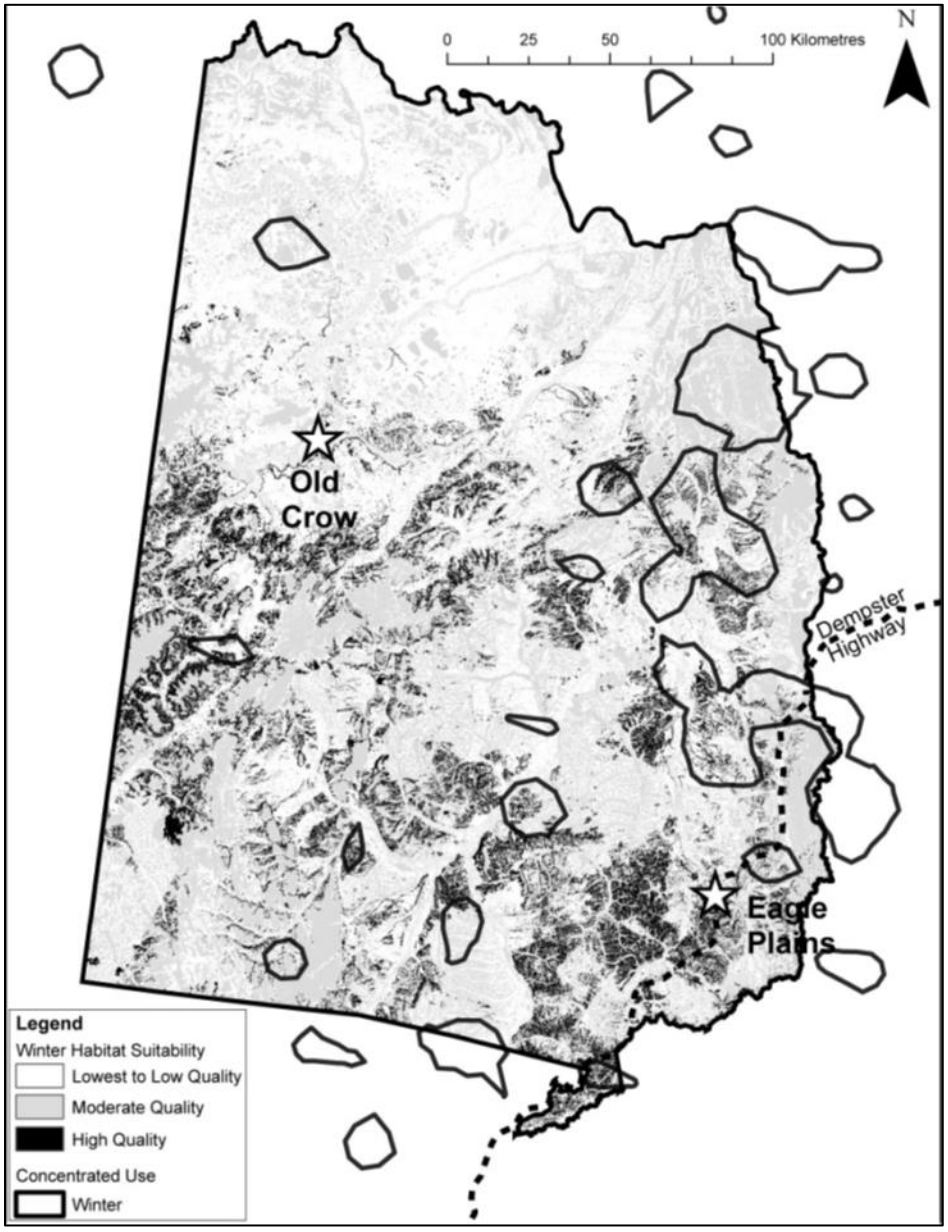

Figure 12: Overlay of concentrated use areas and habitat suitability map for the winter season. Concentrated use areas (thick black outline), high quality habitat (black shading), moderate quality habitat (light grey shading), and lowest to low quality habitat (no shading) are shown.

The International Porcupine Caribou Board (IPCB) developed a booklet in 1993 titled “Sensitive Habitats of the Porcupine Caribou Herd”. In this document, the IPCB presents an assessment criteria of seasonal habitats across the periods shown in Table 4:

Table 4: Assessment of criteria of seasonal habitats

TABLE 2

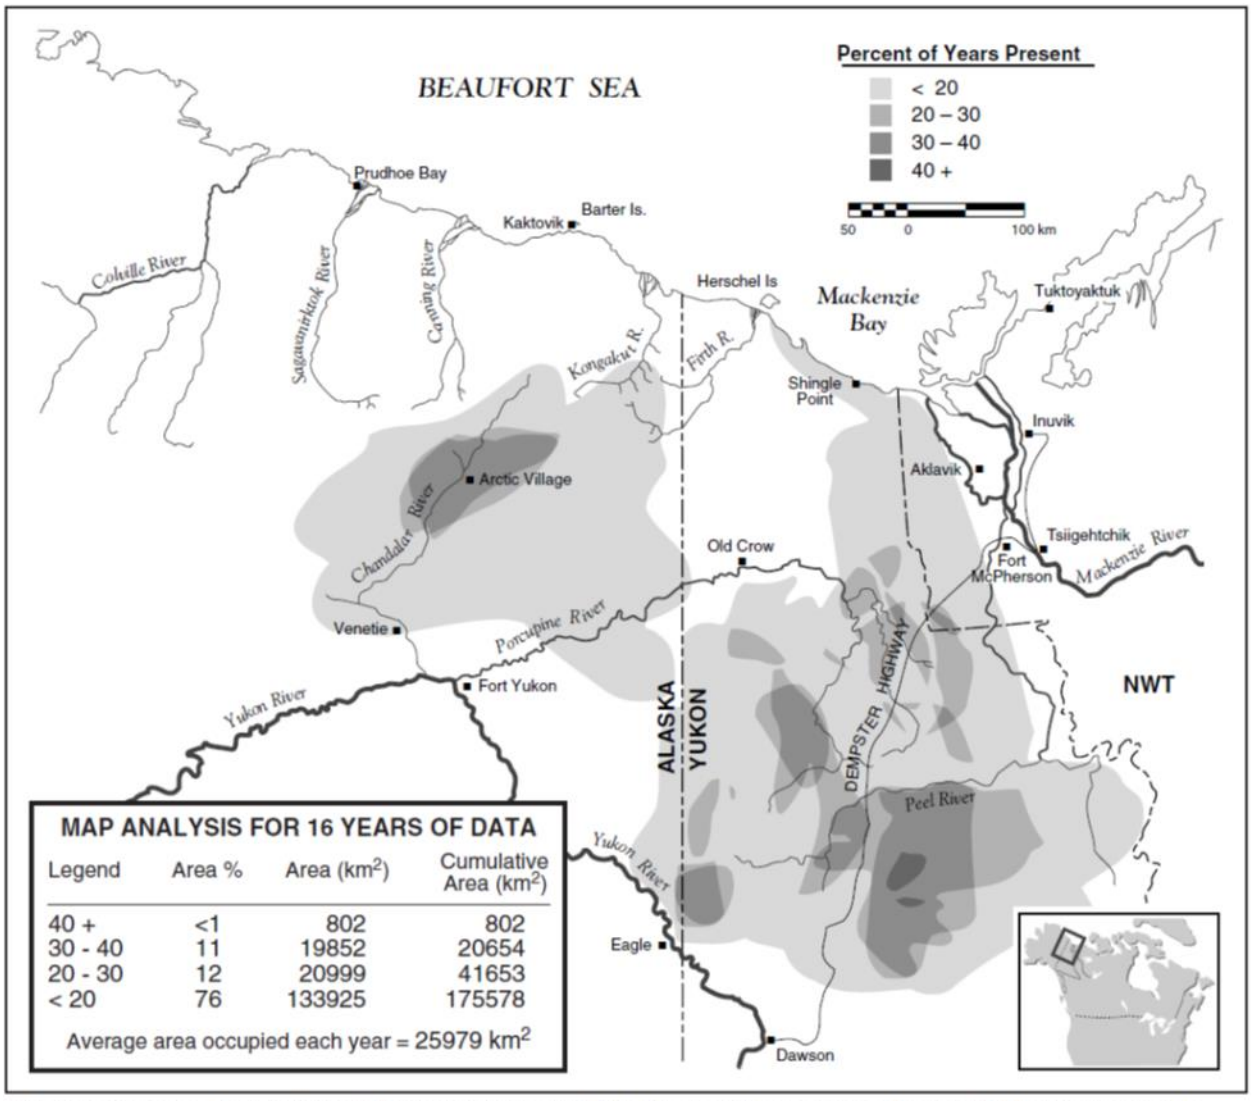
ASSESSMENT OF CRITERIA OF SEASONAL HABITATS

PERIOD	CRITERIA[1]						TOTAL[2]	IMPORT[3]
	energy balance	reproductive contribution	tolerance to disturbance	escape requirements	intensity of use	alternatives available		
Early, Mid and Late Winter 1 Dec. - 31 March	2	3	3	3	3	3	17	4
Spring, Spring Migration and Pre-calving 1 April - 31 May	1	2	3	3	3	2	14	3
Calving (cows) 1 - 10 June	1	1	1	1	1	1	6	1
Calving to Movement (bulls) 1 - 30 June	3	3	2	3	2	1	14	3
Post-calving and Movement (cows) 11 - 30 June	2	1	1	1	1	1	7	1
Early Summer 1 - 15 July	1	2	2	1	1	2	9	2
Mid Summer 16 July - 7 Aug	1	2	2	1	2	2	10	2
Late Summer and Fall Migration 8 Aug - 7 Oct	3	1	3	3	3	2	15	3
Rut and Late Fall 8 Oct - 30 Nov	3	3	3	3	3	3	18	4

[1] scores - based on a 1 - 2 - 3 rating (1 = highest concern)
[2] total of criteria ratings
[3] level of importance (1 = highest importance)

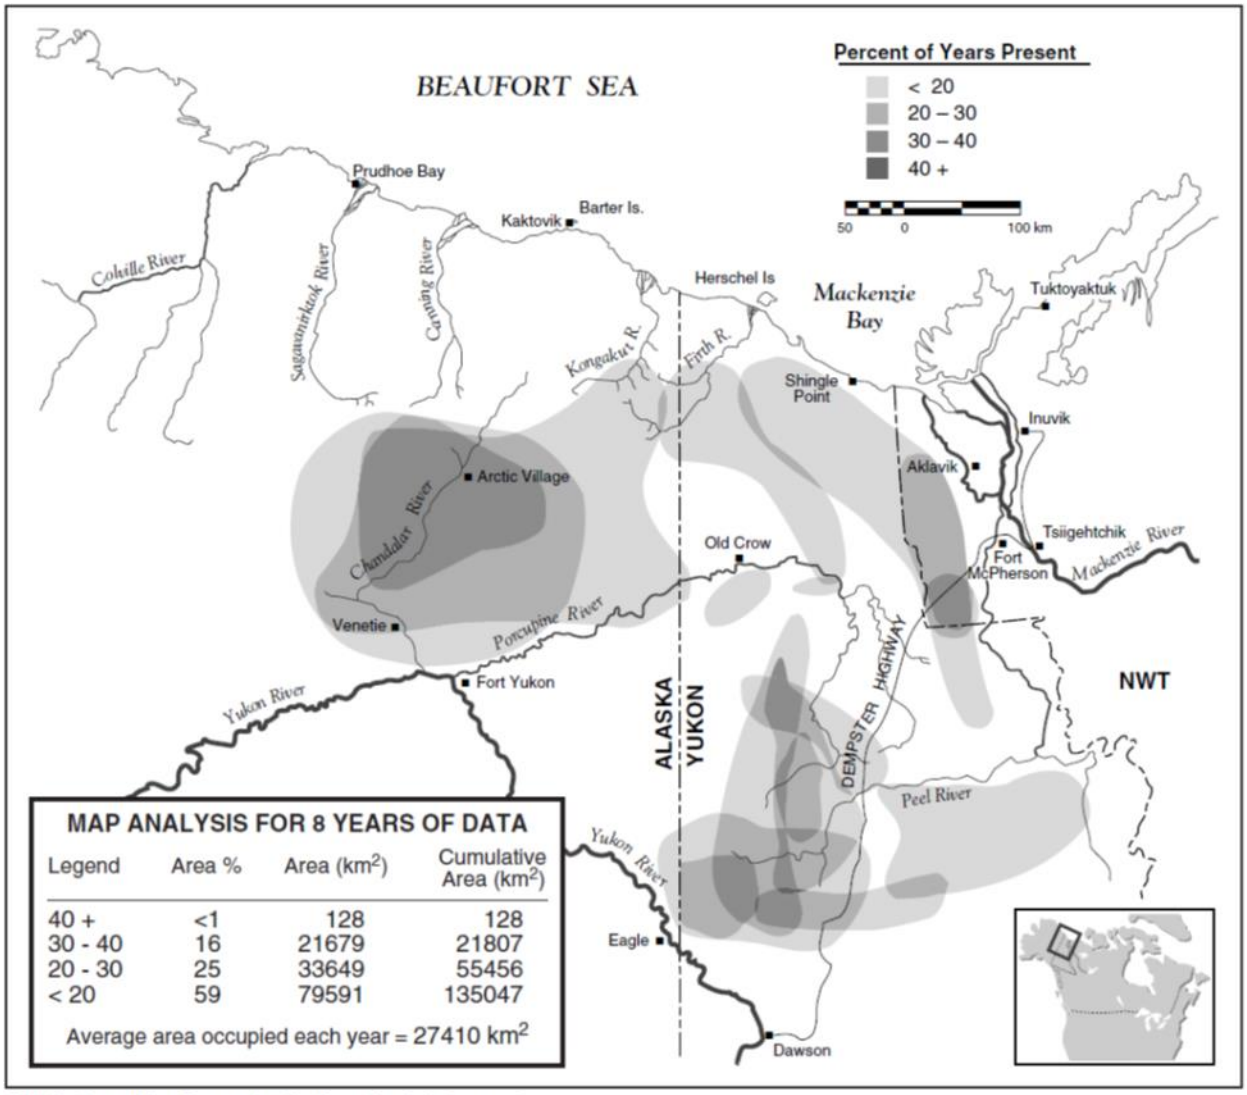
Based on review of maps provided by the PCMB and those documented by Ryder et.al, the Project area overlaps with these periods from September – April. The assessment done by the IPCB suggests that the level of importance attributed to habitat for this period of time is less than the level afforded the habitat for calving. This is based on how they scored the level of importance for the following criteria: energy balance, reproductive contribution, tolerance to disturbance, escape requirements, intensity of use, and availability of alternatives. While the Designated Office has considered this perspective, it has also considered the perspective of the PCMB provided during the assessment which stated that: "although winter is not considered as crucial as periods like calving, whatever happens to PCH in winter can affect calf survival rates, the following year’s pregnancy rates, along with every aspect of the caribou’s productivity from age of first reproduction to calf survival" (YOR 2014-0112-113-1).

The following maps (Figure 13, Figure 14 and Figure 15) were included in the IPCB's booklet and further demonstrate a general understanding of the overlap between the rut, over-wintering and spring migration of the PCH in relation to the Project area.



This map represents the distribution of the herd in late winter for all years with data. Early and mid-winter distributions tend to overlap with late winter distributions.

Figure 13: Porcupine Caribou Herd distribution in late winter for all years with data



Distribution of the Porcupine Caribou Herd during spring.

Figure 16 depicts the areas within and near the Project area affected by forest fire since 1970.

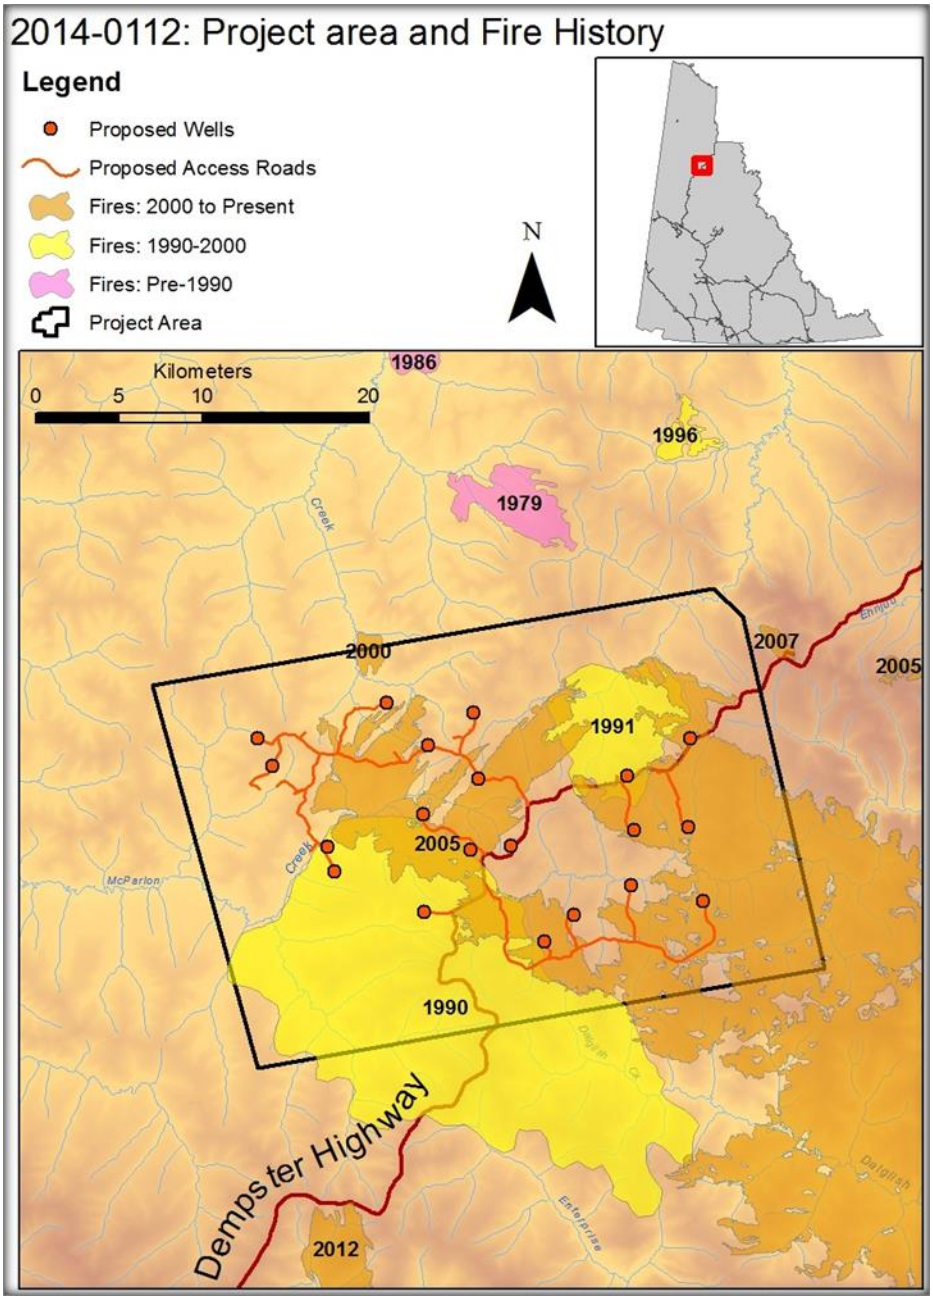

Figure 16: Fire history in the Project area from 1970 onwards.

Appendix D ZONE OF INFLUENCE

In attempting to understand the potential significant adverse effects of this Project to access to and use of the PCH, the Designated Office considered the potential ZOI that Project activities could impose. The ZOI refers to the area in which a species changes its behaviour, habitat selection, and distribution due a particular activity or development. ZOI are generally associated with negative changes to habitat selection, distribution, and behaviour. ZOI may also be used to characterize potential adverse effects to access to and use of the PCH as a result of Project activities.

Russell (2014) summarizes the ZOI from multiple projects affecting caribou, but most relevant to this Project are displacement distances caused by all-season roads and point-source disturbances. He identifies in his review a ZOI of 4 km during construction of all-season roads and 1.5 km during road operations for barren-ground caribou in the NWT and NT, noting that projects there have acknowledged that ZOI may reach out to 5 km for exploration activities and road components alone. Johnson and Russell (2014) found low densities or widely distributed but low use access roads and 2D seismic lines were avoided by the PCH in this area by 11 km shortly after their development and reducing that avoidance to 6 km following at least 20 years of non-use. As indicated by the PCMB, avoidance of the Dempster Highway was 30 km shortly after construction and reducing to 18.5 km after the features had been present for at least 20 years (YOR 2014-0112-133-1).

Figure 17 provides a visual of the potential ZOI caused by this Project as identified by Mr. Russell and the PCMB. Using a ZOI model, disturbances to caribou extend beyond the relatively small area of projected direct disturbance identified by the Proponent and considered in the threshold discussion in the NYRULP conformity check. Where the surface and linear disturbance indicators used in the conformity check are meant to measure direct disturbances to caribou and their habitat resulting from Project activities, a ZOI is arguably a better indicator of adverse effects to caribou in relation to disturbance and habitat avoidance. The NYRLUP does not speak to ZOI in terms of indicators or thresholds of disturbance. The ZOI for existing past development within land management unit #9, in which the proposed Project is based, is currently unknown in relation to critical habitat or within the range of the PCH.

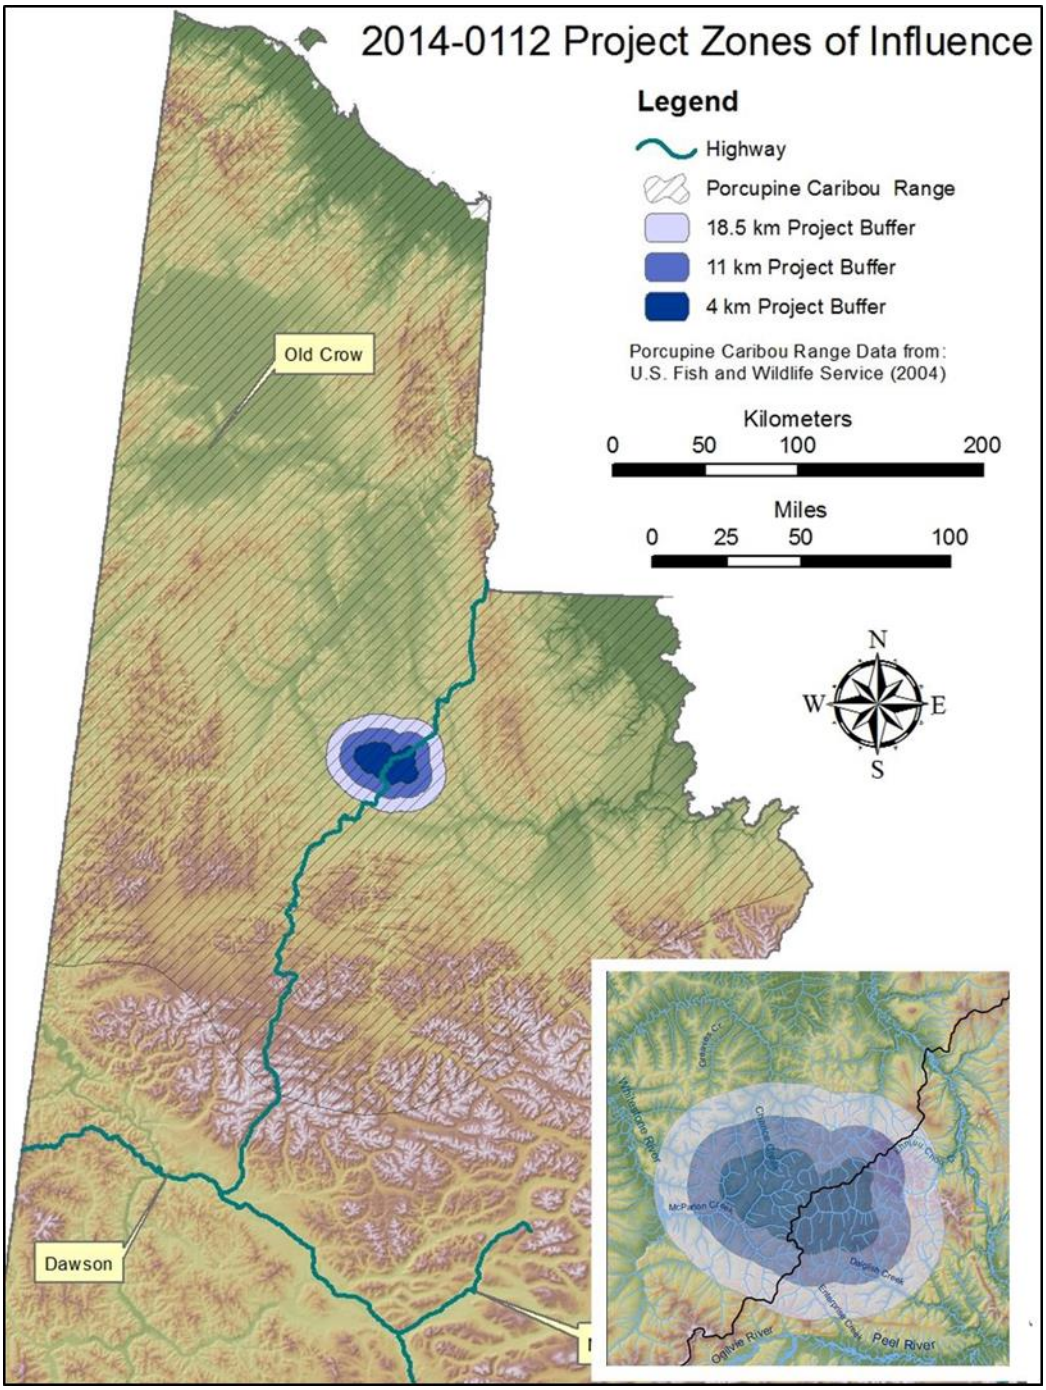

Figure 17: Estimated zone of influence for Porcupine Caribou in relation to potential avoidance of activities associated with Project 2014-0112

Appendix E CONSIDERATION OF THE NORTH YUKON REGIONAL LAND USE PLAN

In 2009 the NYRLUP was approved by the Government of Yukon and the VGFN. The plan was developed and recommended by the North Yukon Planning Commission. This commission was established by the Yukon Land Use Planning Council as per chapter 11 of the Umbrella Final Agreement.

The NYRLUP was developed in accordance with the principles of sustainable development, precautionary principle, conservation and adaptive management and set out to achieve the following goals:

- Promote sustainable development by ensuring that social, cultural, economic and environmental policies are applied to the management, protection and use of land, water and resources in an integrated and coordinated manner.
- Maintain terrestrial habitat in a condition required to sustain regional wildlife populations.
- Maintain aquatic habitat in a condition required to sustain regional fish populations.
- Maintain the integrity of wetlands, lakes, rivers and sensitive permafrost areas.
- Recognize, conserve and promote the heritage and cultural resources and values of the Vuntut Gwitchin, other affected First Nations, and the Yukon.
- Facilitate economic development opportunities and activities that result in socio-economic benefits to the community of Old Crow, other affected First Nations and Yukon as a whole, and that meet the sustainable development criteria established by this Plan. (North Yukon Planning Commission, 2009)

The plan provides important guidance for wildlife in general and specifically for the PCH. Figure 18 identifies the objectives and strategies in relation to wildlife:

GOAL 2 – WILDLIFE **Maintain terrestrial habitat in a condition required to sustain regional wildlife populations.**	
OBJECTIVES	STRATEGIES
2.1. Minimize direct and indirect human-caused habitat disturbance and alteration.	2.1.1 Reduce size, intensity and duration of human-caused physical surface disturbances (e.g., utilize low impact seismic, winter roads and enhanced reclamation). 2.1.2 Reduce other human land use impacts such as noise, smell and light.
2.2. Minimize habitat fragmentation as a result of human features.	2.2.1 Coordinate, manage and minimize new road and trail access.
2.3. Minimize potential habitat avoidance that results from human features and activities.	2.3.1 Avoid or reduce activities in significant wildlife habitats during important biological periods (e.g., utilize timing windows).
BEST MANAGEMENT PRACTICES – GENERAL	• Avoid or minimize the creation of new access roads and trails; utilize existing routes unless their use will cause additional long term environmental impacts (e.g., permafrost degradation). • Avoid or minimize the size, extent, duration and level of activities in concentrated seasonal use areas. • Use appropriate operational timing-windows in significant wildlife habitats to minimize activities, whenever possible, during periods of wildlife use. • When new access creation is necessary: o Non-permanent winter access routes should be developed and utilized versus all-season access routes. o Gate or otherwise restrict hunting along new access routes. o Where possible, direct new access routes through less significant wildlife habitats.
INDICATORS	• Surface disturbance. • Linear density. • Other indicators to be determined through future research and plan implementation.

Figure 18: NYRLUP - objectives, strategies and best management practices for wildlife

The plan also provides the following best management practices for the PCH:

- Avoid or minimize the size, extent, duration and level of activities in concentrated seasonal use areas.
- Avoid using or crossing seasonal migration corridors with new access routes.
- Define and implement safe operating distances from the herd.

- Consider the following seasons when determining appropriate operational timing-windows:

Winter:	December 1 to March 31
Spring migration:	April 1 to May 31
Early summer:	July 1 to July 15
Mid to late summer:	July 16 to August 7
Fall migration:	August 8 to October 7
Rut:	October 8 to November 30

The planning region is divided into thirteen land management units (LMU). The project is located within LMU#9 - Eagle Plains, an area representing 11% of the planning region. The plan provides special management considerations and of relevance to this assessment is the following recommendation:

> "potential new all-season access roads into LMU#9 from Dempster Highway corridor require careful assessment and management." (North Yukon Planning Commission, 2009)

The plan identifies Eagle Plains access management as a key issue and recommends that "in advance of significant levels of energy sector activity, an access management plan should be developed for the Eagle Plain oil and gas basin." (North Yukon Planning Commission, 2009)

The plan also identifies the following key issues in relation to the development of oil and gas reserves within this management unit (note: only content relevant to this assessment is quoted):

- Coordinated and effective management of the Porcupine Caribou Herd habitat and population requires and integrated approach, in advance of increasing industrial use.
- Land use conflicts might arise between: b) oil and gas and traditional economic activities and cultural pursuits, and c) oil and gas and Porcupine Caribou Herd use of winter range.

The plan concludes in this section that "specific recommendations relating to the management of oil and gas exploration and development activities are not required at this time… existing best management practices, used in combination with the direction provided by this Plan, are considered adequate to mitigate potential impacts of oil and gas activity." (North Yukon Planning Commission, 2009)

The NYRLUP provides important guidance to the assessment of this project. There are two caveats to the utility of this plan for this assessment. First, the plan is an expression of the interests and vision of the VGFN and the Government of Yukon for the North Yukon The plan does not formally capture the interests and vision of other First Nations and the Inuvialuit in relation to the PCH and their habitat. Second, the plan recommends two landscape disturbance indicators (i.e. surface disturbance in hectares and linear disturbance in kilometres) to track potential cumulative effects of land use. The plan includes cautionary and critical thresholds of land use within each LMU. These thresholds are intended to provide a clear statement regarding the level of human-caused environmental change (i.e. functional disturbance) that might be considered acceptable within a specific LMU. While these indicators are important to consider, determining the significance of effects necessarily consider factors beyond these concise parameters.

APPENDIX B. Linear Feature Study

Chance Oil and Gas, Eagle Plains Project: Linear Feature Study

EXECUTIVE SUMMARY

The Eagle Plains Exploration Project (the Project) is an oil and gas exploration project located in north Yukon. Chance Oil and Gas Ltd. (Chance) intends to conduct exploratory activities to confirm the quality, quantity, and extent of hydrocarbons over ten years. Work will include seismic exploration and exploratory wells supported by an expanded winter road network. Oil and gas exploration activities create long, narrow clearings through natural vegetation, such as seismic lines and roads, collectively known as 'linear features.' Linear features can be a management challenge because they can affect how people and animals move and plants disperse within a landscape. For example, in southern parts of the boreal forest, linear features appear to affect predator-prey dynamics that can result in increased caribou mortality by wolves. The North Yukon and Peel Watershed Regional Land Use Plans identify mitigations to minimize the potential effects of linear features, including cautionary (0.75 km/km^2) and critical (1.0 km/km^2) indicator levels of linear disturbance.

Intermittent exploration activities in the Eagle Plains area from the 1950s to 2014 have created a network of winter roads, 2D seismic lines, and, most recently, 3D seismic lines in parts of the Regional Study Area (RSA). However, the extent of liner features that currently occur in the RSA, the structural, vegetation, and functional characteristics of different linear feature types, and their degree of regeneration are unknown. EDI Environmental Dynamics Inc. conducted a linear features study to characterize the structural, vegetation, and functional aspects of linear features in the RSA to address these information gaps. The study addressed three objectives: (1) comprehensive mapping and classification of existing linear feature footprints within the RSA; (2) quantification of structural aspects (e.g., widths) and functional aspects (ease of travel and sightlines) of linear features; and (3) quantification of regeneration pathways and structural stages of linear features. This combined information supports assessing potential effects of linear features in the Project application and refinement of mitigation measures for linear features to minimize possible effects.

The linear features inventory was compiled from multiple spatial datasets and was verified and supplemented using satellite imagery in a Geographic Information System. Linear feature densities were estimated for each linear feature type. Estimates were adjusted to account for (i) overlap with open habitats, such as recent burns, where vegetation heights were similar on and off the line, and (ii) for average rates of regeneration determined from field studies.

Site selection used a stratified random design to obtain a representative sample of different feature types across the RSA. Ground and aerial surveys measured specific structural, vegetation, and functional characteristics across the different line types. Measures included width, successional class, structural stage, vegetation composition and height, and sightline distances. A 'walk test' was used to index ease of movement for large mammals. A driving survey documented the visibility of seismic lines from the Dempster Highway (i.e., as an index of potential human access onto the seismic lines). An aerial winter track survey was conducted in March 2020 to assess ungulates' relative use of different linear feature types.

Four primary types of linear features occur in the RSA, totalling 4,269 km: 2D seismic (34%), 3D seismic (51%), winter roads (14%), and the Dempster Highway (1%). The unadjusted linear feature density for the RSA totalled 1.79 km/km^2. After accounting for burns, natural openings and regeneration, the adjusted linear

feature density for the RSA totalled 0.52 km/km², below the cautionary and critical indicator levels in the North Yukon and Peel Watershed Regional Land Use Plans.

Structural, vegetation, and functional characteristics differed substantially among linear feature types. 3D seismic accounts for the largest extent of linear features in the RSA and had the narrowest widths and limited functional effects (e.g., the proportion of features used by ungulates in the winter was less than a third of the rates of use on 2D and winter roads). Winter roads had the widest average widths and the greatest functional effects except for the Dempster Highway. However, a substantial portion (39%) had also regenerated into or past the Tall Shrub stage (which this study suggests may be the best criterion for functional recovery). Most 2D lines had substantial vegetation regeneration, resulting in the shortest average sightlines and slowest movement speeds. However, ungulates still appeared to select them to travel on during winter.

Except for the Dempster Highway, where walking speeds were near twice the rate of other linear feature types, there was relatively little difference in movement rates among linear feature types and control areas. The density of shrubs and trees primarily limited movement rates. 2D lines, which had the highest density of shrubby regeneration, had the slowest average movement rates. For other linear feature types, the combination of vegetation regeneration on linear features and the naturally open nature of most adjacent undisturbed areas did not convey a substantial increase in movement rates on linear features compared to undisturbed areas.

Sightline distances on 2D lines and winter roads were also affected mainly by the degree of vegetation regeneration. Where regeneration was limited, sightlines on 2D lines and winter roads regularly exceeded 150 m. On 3D lines, which have not had enough time since their creation for vegetation to regenerate to the height that restricts vision, sightlines were limited by meanders purposely constructed to reduce sightlines. The meanders employed on 3D lines were also effective in reducing the detectability of the lines from the Dempster Highway. In the blind test, where observers did not know the location of the 3D lines, only 5% (4 out of 74) crossings were spotted. With a map showing the crossing locations, only two additional 3D lines were detected.

These results provide information to assess the potential effects of linear features in the Project application and refine mitigation measures.

ACKNOWLEDGEMENTS

EDI Environmental Dynamics Inc. (EDI) completed the work within the traditional territories of the Vuntut Gwitchin First Nation (VGFN), First Nation of the Na-Cho Nyäk Dun, and the Tetlit Gwich'in Council (Secondary Use Area). Tyrel Kassi, a VGFN citizen, played an active role in the field components of the project. We thank him for his diligence and shared perspectives during the project.

1 INTRODUCTION

1.1 PROJECT OVERVIEW

The Eagle Plains Project (the Project) encompasses a 2,386 km² area in north-central Yukon, approximately 605 km north of Whitehorse and 40 km south and west of Eagle Plains hotel, along the Dempster Highway (Map 1-1). The Project occurs within the Eagle Plains petroleum basin, north of the Ogilvie River and west of the Richardson Mountains. The basin contains proven natural gas and oil reserves (Peel Watershed Planning Commission 2019), including 4.6 billion m³ of gas and 3.2 million m³ of oil (Hannigan 2014).

The Regional Study Area (RSA) has had intermittent periods of oil and gas exploration since the 1950s. That activity has developed winter roads, seismic lines, and exploratory wells across parts of the current RSA. Approximately 40 exploration wells have been drilled at Eagle Plains. Eight wells are maintained in suspended status, and the remaining wells have been plugged and abandoned. Seismic exploration has included approximately 10,000 km of two-dimensional (2D) lines (mainly before 1985), and about 325 km² of three-dimensional (3D) seismic was conducted in 2013–2014 (Northern Cross (Yukon) Ltd. 2014).

The current exploration program will build on past exploration to better define the extent, amount and quality of oil and gas deposits. Under the current program, Chance Oil and Gas Ltd. proposes conducting additional 3D seismic over large extents of the RSA and drilling up to 30 exploratory wells. Depending on the drilling program results, extended flow testing over several months may be conducted at a subset of the wells to determine the quantity and quality of the oil and gas deposit. The existing winter road network will be expanded to support the seismic and drilling programs. Most work is expected to be conducted in the winter (e.g., seismic line clearing and drilling); however, seismic recordings and extended flow testing may also occur during summer.

Oil and gas exploration activities create long, narrow clearings through natural vegetation, such as seismic lines and roads, collectively known as 'linear features.' Linear features can be a management challenge because they can affect how people and animals move and plants disperse within a landscape. For example, in southern parts of the boreal forest, linear features appear to affect predator-prey dynamics that can result in increased caribou mortality by wolves. The North Yukon and Peel Watershed Regional Land Use Plans identify mitigations to minimize the potential effects of linear features. The Plans also include cautionary (0.75 km/km²) and critical (1.0 km/km²) linear density indicator levels.

1.2 PURPOSE AND OBJECTIVES

Intermittent exploration activities in the Eagle Plains area from the 1950s to 2014 have created a network of winter roads, 2D seismic lines, and, most recently, 3D seismic lines in parts of the RSA. However, the extent of liner features that currently occur in the RSA, the physical and functional characteristics of different linear feature types, and their degree of regeneration are unknown.

EDI Environmental Dynamics Inc. (EDI) conducted a linear features study to characterize the physical and functional aspects of linear features in the RSA to address these information gaps. The three objectives of this study were to: (1) conduct comprehensive mapping and classification of existing linear feature footprints within the RSA; (2) determine physical aspects (e.g., widths) and functional aspects (ease of travel and sightlines) of linear features; and, (3) quantify regeneration pathways and stages of linear features. The combined information forms the basis for assessing the potential effects of linear features in the RSA and refining mitigation measures for linear features.

1.3 STUDY AREA

The RSA for the Eagle Plains Project is approximately 2,386 km² (238,566 ha), centred in the Eagle Plains Ecoregion in north Yukon (Map 1-1). The area consists of subdued topography of rolling hills and sloping plains. The RSA is centred on a major watershed divide (denoted by the location of the Dempster Highway), with the northwestern two-thirds of the RSA draining into the Porcupine River watershed to the north, via Chance Creek, and west, via McParlon Creek and the Whitestone River. The southeastern third of the RSA drains into the Peel River watershed via Dalglish Creek.

Development in the RSA and the surrounding Eagle Plains is low. The Dempster Highway is the primary vehicle access corridor, running from approximately Dawson City, Yukon in the south to Inuvik, Northwest Territories in the north, and transiting the RSA. The Eagle Plains settlement is on the Dempster Highway, approximately 40 km northeast of the RSA and includes the Eagle Plains Hotel and the Government of Yukon's Highway Maintenance camp. The Eagle Plains area has had intermittent periods of oil and gas exploration since the 1950s. That activity has created winter roads, seismic lines, and exploratory wells across parts of the RSA. Approximately 40 exploration wells have been drilled at Eagle Plains. Eight wells are maintained in suspended status, and the remaining wells have been plugged and abandoned. Approximately 10,000 km of 2D lines have been developed across the Eagle Plains Ecoregion, mostly between 1961 and 1984 (Access Consulting Group and EBA Engineering Consultants Ltd. 2001, GEOTIR 2014). More recently, approximately 2,200 km of 3D LIS exploration was conducted in a 325 km² area between November 2013 and April 2014 (GEOTIR 2014). This 3D exploration grid is near the centre of the RSA, spanning north and south of the Dempster Highway.

1.3.1 REGIONAL ECOLOGICAL SETTING

The Eagle Plains Ecoregion is a 20,400 km² portion of the Taiga Cordillera Ecozone in north Yukon between the Richardson and Ogilvie Mountains. Unlike much of the mountainous Taiga Cordillera, most of the Eagle Plains Ecoregion occurs as low altitude rolling topography between 300 m and 600 m above sea level (masl), with few scattered peaks above and around 1,000 masl (Ecological Stratification Working Group 1995). Most of the ecoregion is unglaciated terrain, with surficial features formed due to permafrost and frozen ground-related processes, including thermokarst subsidence, soil creeps, cryoturbation, solifluction, and active layer detachment slides on shale (Yukon Ecoregions Working Group 2004).

The Eagle Plains Ecoregion experiences moderate precipitation, with annual amounts around 400 mm. Most precipitation falls as rain throughout the summer, averaging 50 to 80 mm per month, June through August. Precipitation is lighter through September to April and falls as snow, with average winter snowpacks of 80 cm peaking in April. The climate is strongly affected by latitude, with extended winter conditions from October to early May. There is a substantial variation in seasonal temperatures in the Eagle Plains, with cool short summers and long cold winters. Average winter temperatures are between −30°C and −25°C, with extremes as low as −60°C. Average summer temperatures are around 13°C, with extremes as high as 30°C. Due to the northern latitude, this region experiences continuous sun above and below the horizon, in summer and winter, respectively.

Most of the Ecoregion, including the northeast portion of the RSA, drains north into the Yukon River via the Whitestone, Porcupine and Eagle rivers. That part of the RSA includes the headwaters of the Eagle River and several other tributaries of the Porcupine River, along with the Chance and McParlon Creek subdrainages of the Whitestone River. The southeast corner of the Ecoregion drains east to the Mackenzie River via the Peel, Wind and Ogilvie Rivers. Dalglish and Enterprise creeks flow directly into the Peel River. The few lakes in the Ecoregion are generally oxbow or thermokarst lakes (Yukon Ecoregions Working Group 2004). Several wetland complexes are associated with larger creeks in the RSA.

The Eagle Plains Ecoregion is within the continuous permafrost zone where permafrost can be found up to 200 m thick. The Eagle Plains Ecoregion is dominated by the Cryosolic soils that occupy much of the northern third of Canada, characterized by near-surface permafrost. Turbic Cryosols predominate, exhibiting patterned ground formations and hummocks, and are often associated with open stands of black spruce (*Picea mariana*), tamarack (*Larix laricina*) and birch (*Betula* spp.). The active permafrost layer in these ecosystems generally ranges between 20 cm and 90 cm below the surface. The active layer depth is generally deeper directly under hummocks and shallower under inter-hummock areas (Yukon Ecoregions Working Group 2004).

The RSA is entirely within the Subarctic Bioclimate Zone (Environment Yukon 2014). Vegetation in the RSA is characterized by open-canopy, spruce-dominated habitats where permafrost and short cool growing seasons limit tree growth and often result in stunted, disclimax vegetation communities (Environment Yukon 2016). Hummocky, black and white spruce (*Picea glauca*) woodlands with well-developed shrub communities are common in upland areas. White spruce and ground lichens increase in abundance in well-drained sites. Areas with low slope gradients and fine-textured soils often have ground cover dominated by cottongrass tussocks beneath a shrub layer of birch, black spruce, Labrador tea (*Rhododendron groenlandicum*), and occasionally tamarack (*Larix laricina*) (Yukon Ecoregions Working Group 2004).

Forest fires are a common disturbance agent in the region, and burns of various ages occur throughout the RSA. Fires increase the depth of the active permafrost layer and changes in soil moisture and productivity, affecting vegetation regeneration and resulting in terrain disturbances, such as slope failures and erosion. Regenerating burns are dominated by shrubs, such as scrub birch (*Betula glandulosa*), willows (*Salix spp.*) and alder (*Alnus spp.*), with Alaskan paper-birch (*Betula neoalaskana*) often the first tree species to colonize burn areas. As burns regenerate into young and mature forest, black and white spruce typically become the dominant forest species. Residual Alaskan birch in spruce-dominated stands often defines the extent of old burns (Yukon Ecoregions Working Group 2004).

Mammal diversity is relatively low in the Eagle Plains Ecoregion due to its northern location and low productivity. Voles (*Microtus* spp., *Myodes* spp., *Phenacomys* spp.), American marten (*Martes americana*), ermine (*Mustela erminea*), and red fox (*Vulpes vulpes*) are common smaller mammals. Wolves (*Canis lupus*), wolverines (*Gulo gulo*), and both black and grizzly bears (*Ursus americanus* and *U. arctos*.) are present at low densities. Moose (*Alces alces*) inhabit the region year-round. The RSA overlaps a small portion of the winter range of the Porcupine caribou herd (PCH), a subpopulation of the barren-ground caribou (*Rangifer tarandus granti*). The PCH is an iconic species in north Yukon, with high cultural, social, economic, and ecological values. The PCH's population has been increasing over the last several decades and is currently estimated to consist of 202,106 to 234,808 caribou (Caikoski 2017, Porcupine Caribou Technical Committee 2018). The PCH is known to occupy portions of the Eagle Plains Ecoregion in fall and winter when they tend to occur in smaller groups over a larger area than during other seasons.

1.3.2 REGIONAL LAND USE PLANNING

The RSA overlaps four First Nation Traditional Territories. Most of the RSA is within the Traditional Territory of the Vuntut Gwitchin First Nation. The southeastern portion is in an area of overlapping Traditional Territories of Vuntut Gwitchin First Nation, the Tetlit Gwich'in Council, the First Nation of Na-cho Nyäk Dun, and Tr'ondëk Hwëchin. Although the RSA is located outside of any First Nation Settlement Lands, it does abut Vuntut Gwitchin First Nations Settlement Lands on parts of its east and southwest borders. Each First Nations government has provided input to, and approved of, the Regional Land Use Plan(s) on their Traditional Territory under the respective First Nation Final Agreements.

1.3.2.1 North Yukon Regional Land Use Plan

The RSA lies mainly within the North Yukon Planning Region and is subject to the North Yukon Regional Land Use Plan (NYRLUP) (Map 1-1). The NYRLUP was created to protect the natural and cultural resources of the region while allowing sustainable economic development opportunities (Vuntut Gwitchin Government and Yukon Government 2009). It provides management direction for using public and settlement lands based on four principles: sustainable development, precautionary principle, conservation, and adaptive management. The NYRLUP divides the Planning Region into 23 land management units classified into three categories: protected area, integrated management area (IMA), and community area. IMAs are further classified into four zones: Zone 1 (lowest development), Zone II (low development), Zone III (moderate development), and Zone IV (highest development). IMA zones are classified based on the area's sensitivity to landscape disturbance, ecological and cultural values, risk of significant impacts, and level of acceptable change. The RSA is a Zone IV IMA with lower ecological and cultural values in a moderately sensitive biophysical setting. Subsequently, Zone IV IMAs allows for the highest development level to occur.

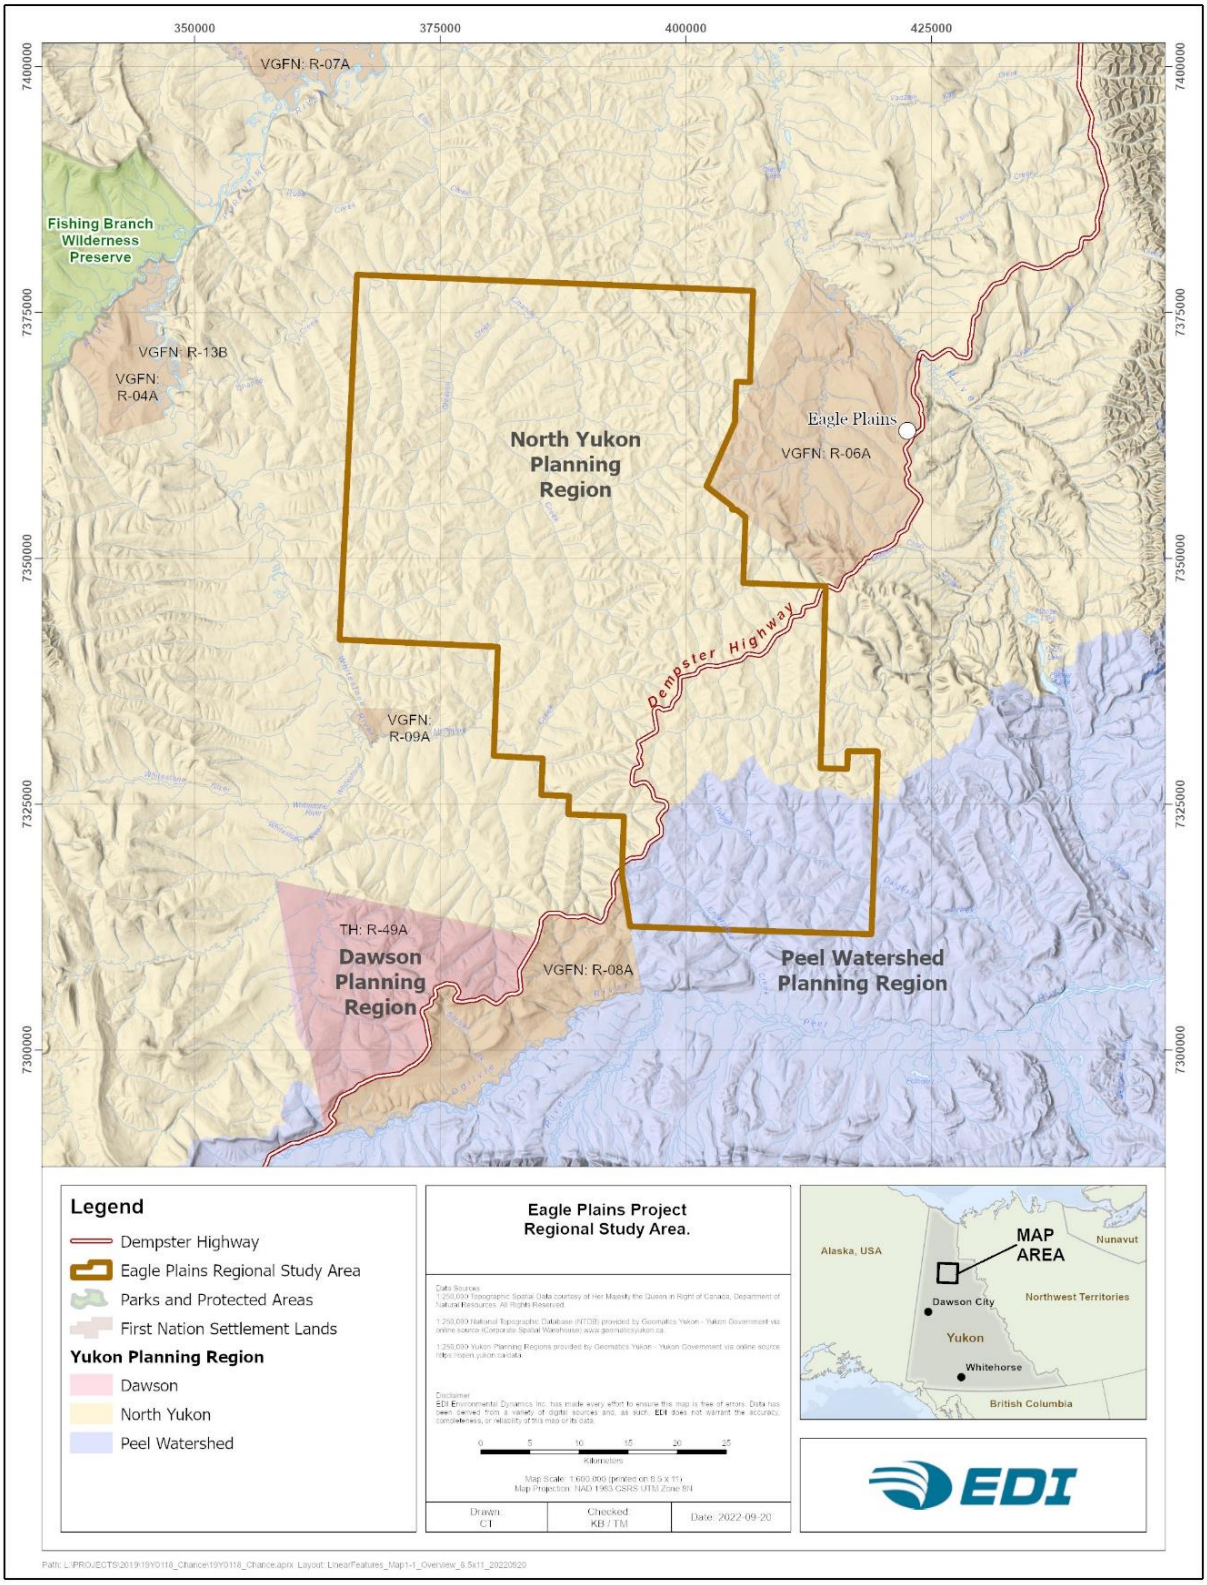
The NYRLUP encourages results-based management and uses cumulative effects indicators to determine if goals and objectives are met. Results-based management allows for innovation and creativity in land-use strategies and approaches. The two cumulative effects indicators included in the NYRLUP are direct surface disturbance and linear density. The NYRLUP guidelines for Zone IV IMAs are 0.75–1.0% surface disturbance and 0.75–1.0 km/km² linear density (Vuntut Gwitchin Government and Yukon Government 2009).

However, as surface disturbances and linear features reach a level of functional recovery and become part of the continuous landscape, they can be subtracted from the total amount of disturbed area (Vuntut Gwitchin Government and Yukon Government 2009). The NYRLUP suggests using a height of 1.5 m for woody vegetation in forested areas, as vegetation above this height would likely no longer allow for travel or access by humans or wildlife and is, therefore, considered functionally recovered. Activities considered exempt from functional disturbance restrictions are (1) new linear features less than 1.5 m wide; (2) land-use activities that occur on frozen water bodies; (3) winter work with no required clearing of trees; and (4) winter work that uses existing disturbances and linear features.

1.3.2.2 Peel Watershed Regional Land Use Plan

The southeastern corner of the RSA lies within the Peel Watershed Planning Region (PWPR) and is subject to the Peel Watershed Regional Land Use Plan (PWRLUP) (Peel Watershed Planning Commission 2019) (Map 1-1). Like the NYRLUP, the PWRLUP was established to provide management direction and ensure long-term sustainable development in the Planning Region. The PWRLUP was founded on three main themes: environmental protection, social considerations, and economic development. It follows a similar framework as the NYRLUP. The PWPR is divided into 16 Landscape Management Units (LMU), which each share similar ecological characteristics, planning issues, and management intent. Each LMU is categorized by a land-use designation system. Conservation Areas are managed to protect ecological and cultural resources, while IMAs are 'working' landscapes where new development and surface disturbance may be allowed. IMAs are further classified into Zones, which correspond to the level of allowable development with comparable justification as the NYRLUP. The RSA is part of LMU 7 (Dalglish Creek), classified as an IMA Zone IV, allowing for the highest level of development.

Like the NYRLUP, the PWRLUP encourages results-based management and uses the same cumulative effects indicators, surface disturbance and linear density to inform decisions. The PWRLUP cautionary and critical indicators are identical to those of the NYRLUP: 0.75–1.0% surface disturbance and 0.75–1.0 km/km² linear density. As surface disturbances reach a level of functional recovery and no longer enable travel or access by wildlife and people, they can be subtracted from the total amount of disturbed area. The PWRLUP suggests using a 1.5 m woody vegetation height as a threshold for functional recovery in forested or shrubland areas. In areas dominated by low-growing vegetation, a feature could be considered functionally recovered when covered by native species roughly the same height and composition as the surrounding vegetation. To be considered as "functionally recovered," features must have similar sediment and run-off compared to background levels, roughly match original contours, and have no human-brought materials on the site. Exceptions to the linear density calculation are identical to those outlined in the NYRLUP.



Map 1-1. Eagle Plains Project Regional Study Area.

2 BACKGROUND

The term "linear feature" refers to any narrow, linear clearings of vegetation on the landscape. They include roads, seismic lines, power lines, and pipelines. Seismic lines are the dominant linear feature class in northern Canada, accounting for approximately 46% of all linear features in the Canadian boreal region (Pasher et al. 2013). Seismic exploration detects underground oil and natural gas reservoirs by analyzing sound waves reflected from the underlying geology (Yukon Energy Mines and Resources 2006). Sound waves are emitted by detonating small charges in a series of drilled shot holes (up to 20 m deep) or by vibrating a heavy metal plate on the ground's surface using a truck-mounted vibrator (Yukon Energy Mines and Resources 2006). Both methods require cleared travel corridors for equipment transportation, which results in a network of seismic lines across the landscape where seismic exploration has occurred.

Until the late 1990s, conventional 2D was the primary form of seismic exploration used in North America. 2D seismic lines were created using bulldozers to clear all vegetation in straight swaths, approximately 5–10 m wide in their earliest form. These wide, straight lines were necessary to enable large, heavy equipment movement. This process resulted in significant physical disturbance, often removing most surface vegetation and roots and the top layer of soil (Bliss and Wein 1972). Progressive improvements in 2D seismic exploration methods reduced the environmental impact, such as clearing in winter instead of summer and raising and adding mushroom shoes to the bulldozer blade to reduce soil disturbance. Despite these improvements, many of the 2D seismic lines created in the 1960s and 1970s in northern Canada remain disturbed, with little evidence of ecological recovery (Lee and Boutin 2006, van Rensen et al. 2015).

3D seismic exploration provides more accurate subsurface geological structure data than 2D technology. 3D seismic exploration techniques were developed in the mid-1990s, and their use became widespread in the early 2000s (Dabros et al. 2018). At the same time as the transition to 3D, the seismic industry was transitioning to smaller and more specialized equipment that reduces cost, improves efficiency and reduces environmental impacts. Modern seismic equipment and methods typically use what is referred to as Low Impact Seismic (LIS) methods that minimize line widths and site disturbance and compaction. Typical 3D seismic lines are 2–3 m wide, constructed in 100–500 m spaced grids, and follow meandering rather than straight routes. There have been substantial improvements in the equipment used for 3D seismic line creation: low ground pressure mulchers, lighter equipment, ATV-mounted equipment, mushroom shoes and smear blades, and 'envirodrills' greatly reduce physical and vegetation disturbance (Dabros et al. 2018). These methods often leave the ground vegetation intact and only remove trees and tall shrubs, reducing overall disturbance and facilitating faster regeneration. The location of the seismic line can be adjusted on the fly in the field to minimize impacts, such as avoiding the cutting of large trees.

Continuous advancements in seismic exploration technology have improved geophysical accuracy while simultaneously reducing environmental impact. Numerous studies have examined the effects of linear disturbances on soil, hydrology, vegetation, regeneration, and wildlife responses (see Dabros et al. 2018 for a comprehensive review). Although the bulk of literature focuses on 2D seismic lines, as they have been part of the landscape for over 60 years, there have been several recent studies investigating the effects of LIS and 3D seismic lines (e.g., Kemper and Macdonald 2009a, Kansas et al. 2015, Golder Associates 2016).

Linear features have been associated with various environmental effects, including permafrost thaw, soil compaction and rutting, increased soil moisture and pooling, altered snow cover, temperature and wind patterns, and varied vegetation and wildlife responses (Dabros et al. 2018). In addition to the immediate loss of vegetation, linear features can create extensive edge effects, facilitate non-native or disturbance-induced species establishment, alter species composition, and positively and negatively affect wildlife (Dabros et al. 2018).

One of the most extensively studied effects of linear features in the southern boreal forest is the indirect effects that linear features can have on mortality risk to woodland caribou (*R. tarandus caribou*). Linear features can result in complex effects on populations dynamics that include (i) increases in secondary prey (moose and deer), which elevate wolf populations (apparent competition) and (ii) more efficient hunting by predators along linear features (facilitated predation) (Wittmer et al. 2007, Latham et al. 2011, Dickie et al. 2017a, Keim et al. 2019b, 2021). Research has also documented the responses of birds to linear features (Bayne et al. 2005, Machtans 2006, Lankau et al. 2013), bears (Tigner et al. 2014, Finnegan et al. 2018), and furbearers (Tigner et al. 2015).

Most studies investigating impacts and recovery of seismic lines and other linear features were conducted in southern boreal forest ecosystems (i.e., Boreal Plains Ecozone; e.g., Lee and Boutin 2006, Kansas et al. 2015, van Rensen et al. 2015, Dickie et al. 2017a). There are fundamental differences in the climate, vegetation communities, wildlife communities, and ecological processes in taiga ecosystems that may result in different patterns and responses to linear features. For example, regeneration patterns of linear features in taiga ecosystems over permafrost can follow different successional trajectories than those of southern boreal regions (Simpson 2008). The few studies that have examined linear features in taiga regions have found similarities and differences to southern studies revegetation (Kemper and Macdonald 2009, Dabros et al. 2018). One of the key objectives of this study was to collect local information from Eagle Plains that can be used to better contextualize or adapt the findings from other studies to the Eagle Plains Project.

3 METHODS

A GIS analyses and field surveys were conducted to characterize linear features within the RSA. The inventory of linear features in the RSA was developed in a GIS by compiling available spatial data and then verifying and updating that against satellite imagery. Field studies quantified the width, vegetation characteristics, ecological function (line-of-sight, large mammal ease of movement assessment), and visibility of lines from the Dempster Highway.

3.1 LINEAR FEATURES INVENTORY

The inventory of existing linear features in the RSA was developed in a GIS by compiling available spatial data and then verifying and updating that against satellite imagery. A preliminary linear feature database was first developed that was used to support field surveys (described below in this section). A second step linked the field data to the linear feature database and conducted a more thorough review and verification process using satellite imagery to produce a final linear feature dataset for the RSA (see details in section 3.5.1).

Linear feature spatial data were obtained from the following sources:

- Yukon Government Energy, Mines and Resources "Oil and Gas Seismic Lines" dataset (a combination of less detailed National Energy Board data pre-1999 and the more detailed company-submitted data post-1999) (Yukon Government 2019)
- Natural Resources Canada CanVec "Roads," "Trails," and "Cut Lines" 1:50,000 scale datasets (Natural Resources Canada 2019)

The two datasets were merged into one dataset of all linear features documented in Yukon and clipped to the RSA. Key attribute data included (if available) the linear feature type (i.e., 2D and 3D seismic lines, winter roads, trails, Dempster Highway), width, year of establishment, and data source. This preliminary linear feature dataset was compared against satellite imagery at a (minimum) 1:10,000 scale to verify its accuracy. Any linear features that did not correspond with features visible in satellite imagery were either corrected or deleted based on satellite imagery interpretation. In the case of duplicate features across datasets, the 'best' data were attributed to a single feature by considering the spatial accuracy and the amount and accuracy of attribute data, as assessed against satellite imagery. Where duplicate widths occurred in the two source datasets, the wider width was retained.

3.2 LINEAR FEATURE CHARACTERISTICS SURVEY

Field studies quantified the width, vegetation characteristics, line-of-sight, and large mammal ease of travel assessment across the linear feature types identified from the GIS inventory. One aspect of the field study was to compare vegetation, line-of-sight, and ease of movement on the linear features to undisturbed areas adjacent to the cleared lines. Three types of surveys collected data for the linear feature study: ground surveys

(finest level of detail), air surveys (medium level of detail), and air calls (coarsest level of detail). EDI crews collected field data between July 28 and August 8, 2019.

3.2.1 SITE SELECTION

All ground surveys and aerial surveys occurred at predetermined, random sites. Sample sites were selected using a clustered, random sampling approach. This approach balanced obtaining a random, representative sample across linear feature types with survey efficiency (i.e., without clustering sites, the travel time between points would have been substantially greater and resulted in smaller sample size). Survey sites were drawn from 5,000 points distributed randomly across the set of mapped linear features (minimum spacing of 200 m between points). Each point was randomly assigned a unique number.

Each survey cluster included options for both ground and air surveys. For ground surveys, the cluster used a 2 km radius designed to accommodate approximately four ground survey sites, intended to be surveyed within a half-day of work (and close enough so crews could walk between sites). The objective was that two ground clusters could be surveyed by a crew each day. For air surveys, a 4 km radius was used that generally provided at least ten random survey site options. The objective for air survey clusters was that they could be surveyed while transiting between ground survey clusters.

Survey sites were selected via a two-stage process. The first stage was randomly drawing 100 points from the 5,000-point dataset. These points defined the survey clusters and served as actual survey sites. In this first stage, site selection was stratified to obtain an approximately equal sample across 2D, 3D and winter roads. This overweighted sampling of 2D and winter roads, relative to their extents in the RSA, but those features had the highest uncertainty in terms of their widths, vegetation characteristics, and functional characteristics. Stratification was necessary to obtain sufficient sample sizes across these less-common features. The second site-selection stage selected additional random points from the 5,000-point dataset in proximity to the first point, using the 2 km radius for ground surveys and the 4 km radius for aerial surveys.

The RSA was divided into 10 work areas to implement the sample design, each corresponding to a day of surveys. Each day the survey crew selected clusters to survey using the ascending order of the random identification number of the first point used to define each cluster. Similarly, points within each cluster were prioritized in ascending order of the random identification number. Normally, at least two ground clusters and two air clusters were sampled each day. However, that varied somewhat depending on the number of sample sites available in each cluster and the availability of the helicopter.

3.2.2 LINEAR FEATURE CHARACTERISTICS AND SURVEY METHODS

3.2.2.1 Linear Feature Characteristics

A range of structural, vegetation, human use, and functional characteristics was assessed in the field. A list of the various characteristics examined, with a description of each, is provided in Table 3-1. Successional classes and structural stages of vegetation are defined in Table 3-2 and Table 3-3, respectively.

Table 3-1. Description of physical, ecological and function characteristics assessed in the Eagle Plains linear feature study.

Parameter	Description	Survey Measured [1]
Plot location	Latitude and longitude using WGS 1984, measured by Garmin GPS units to ~4 m accuracy.	G, AS, AC
Linear feature type	Dempster Highway, winter road, 2D, 3Dc (conductor lines), 3Dr (receiver lines), and 3D5 (3D lines used both for seismic and local equipment/vehicle travel.	G, AS, AC
Linear feature width	During ground surveys, measured to the nearest 0.05 m and replicated four times. During aerial surveys, they were visually estimated to the nearest 1 m.	G, AS
Percent mulch	Percent cover of mulch (wood chips) on the seismic line, estimated to the nearest 1% using visual estimates. In areas with dense trees or large shrubs, the thick mulch layer produced during line clearing can hinder vegetation regeneration.	G, AS
Successional class	Refers to the successional trajectory of vegetation regeneration on the linear feature. Includes normal, magnified, stagnated, retrogressive, no succession, or recent disturbance class following Simpson (2008)[1].	G, AS, AC
Burn status	Burnt or not burnt; based on visual assessment (i.e., burned trees, charred ground vegetation).	G, AS, AC
Structural stage	Categorical descriptor of the dominant vegetation life form in the plot following the *Field Manual for Describing Yukon Ecosystems* criteria (Environment Yukon 2017). Structural stage categories are defined in Table 3-3.	G, AS
Height and species of tallest vegetation	Measured to the nearest 0.1 m for the tallest vegetation layer, approximated by the 90th percentile height to exclude extreme heights of individual plants.	G
Cover and species of dominant trees	Percent cover was recorded to the nearest 1% if less than 10%, and to the nearest 5% if over 10%. One or two dominant tree species were recorded.	G, AS
Cover and species of dominant shrubs	Percent cover was recorded to the nearest 1% if less than 10%, and to the nearest 5% if over 10%. Up to five co-dominant shrub species were recorded. Ground shrubs were excluded.	G, AS
Ecosite	Ecosite was recorded using Predictive Ecosystem Mapping (PEM) Units, available at the time of the survey. However, separate vegetation surveys indicated that the accuracy of the PEM mapping was poor, and ecosites were not used in subsequent analyses.	G
Permafrost activity/degradation	Present or absent. Additional comments (i.e., type of activity, percent cover) were recorded if applicable.	G
Wildlife trails	Present or absent. If present, rated as poorly, moderately, or well defined.	G
Potential for Off-Highway Vehicle (OHV) passage	Present or absent. Based on professional judgment, a 4x4 side-by-side is summer, considering obstructing vegetation, ground conditions (e.g., wetlands, peatlands), and graminoid tussocks.	G, AS
Signs of human activity	Present or absent. If present, applicable comments were recorded.	G
Ground disturbance	Percent cover of visibly disturbed ground. If present, type and additional descriptive comments were recorded.	G

[1] G=Ground Survey, AS=Aerial Survey, AC=Air Call.

[2] Between 2006 and 2008, Yukon Government, Department of Energy, Mines, and Resources investigated the recovery status of linear features in the Eagle Plains, British Mountains, and Peel River Plateau Ecoregions (Simpson 2008). They found that linear features typically regenerated into one of six categories: normal succession, magnified succession, retrogressive succession, successional stagnation, no succession, and recent disturbance (Table 3-2).

Table 3-2. Descriptions of successional classes on linear features in the Eagle Plains area (following Simpson 2008).

Successional Class	Description
Normal succession	Vegetation is similar to the adjacent undisturbed area but often in an earlier seral stage. E.g., often young trees surrounded by early successional shrubs and forbs. The disturbance was likely limited to removing trees and shrubs, with little to no disturbance to soil or permafrost.
Magnified succession	Vegetation on the feature is taller than the adjacent undisturbed area. Deciduous species often dominate tree and shrub layers, but a similar pattern was also observed for coniferous trees on some sites. The response is likely due to increased site productivity (including increased soil moisture, nutrients, and temperature) due to soil disturbance or increased depth to permafrost. Most frequently, but not exclusively, observed in burns.
Retrogressive succession	Sites are typically moss or sedge-dominated (rarely forb or low shrub), with high moisture content, often including standing water (i.e., micro wetlands), that contrast to upland conditions in adjacent undisturbed areas. The condition appears to result from permafrost melting and water pooling associated with vegetation removal and removal/compaction of the peat layer and mostly associated with winter roads.
Successional stagnation	Vegetation is typically dominated by graminoids or shrubs and not progressing to more advanced successional stages. Disturbance to soil or permafrost is likely. The ground may have been compacted. Almost exclusively associated with winter roads.
No succession	No ecological differences between the linear feature and adjacent undisturbed areas except that there is no or very little tree or shrub regeneration on the line, other than what was left after creation of the feature. Disturbance appears to be limited to the removal of trees and shrubs, with little to no disturbance to ground vegetation, soil, or permafrost.
Recent disturbance	Newer seismic line where successional patterns could not be determined. Features in this class were most likely trending to 'normal succession' or 'no succession', but the degree of regeneration was too limited to classify confidently.

Table 3-3. Structural stage categories used in ground and air surveys for the Eagle Plains linear feature study.

Structural Stage Code	Structural Stage Name	Description
1	Non-vegetated	Very recent disturbance (e.g., fire or flood) and no vegetation or less than 5% vegetation.
2	Sparse/Cryptogram	Either the initial stages of primary succession or a cryptogram community maintained by environmental conditions (e.g., bedrock, talus). Sparse tree, shrub and herb cover. Either sparsely vegetated overall (low cover of vascular plants and cryptograms, if present) or dominated by cryptograms.
2a	Sparse	5–10% vegetation cover.
2b	Bryoid	Bryophyte-dominated.
2c	Lichen	Lichen-dominated.
3	Herb	Early successional stage (e.g., post-fire forest succession) or a herb community maintained by environmental conditions or disturbance. Vegetation is dominated by herbs, although if the site overall is sparsely vegetated, herb cover can be low as long as herbs characterize the vegetation. Trees and shrubs are usually sparse or absent; however, shrub cover and stature (compared to herb cover and stature) determine whether the site is considered herbaceous.
3a	Forb-dominated	Includes non-graminoid herbs and ferns.

Structural Stage Code	Structural Stage Name	Description
3b	Graminoid-dominated	Includes grasses, sedges, reeds, and rushes.
3c	Aquatic	Floating or submerged plants dominate.
3d	Ground shrub-dominated	Dominated by dwarf woody species such as kinnikinnick (*Arctostaphylos uva-ursi*) or dwarf willows.
4	Shrub	Early successional stage of a forest or a shrub community maintained by environmental conditions or disturbance. Dominated either by shrubby vegetation, including tree seedlings or saplings; or, if sparsely vegetated overall, dominated by shrubs, which characterize the community as a shrubland.
4a	Tall Shrub	Dominated by woody plants >2 m tall with diameter at breast height (dbh) ≤7 cm.
4b	Low Shrub	Dominated by woody plants <2 m tall.
5	Treed: Pole/Sapling	Trees >2 m tall and with dbh >7 cm, typically densely stocked. Self-thinning and vertical structure are not yet evident in the canopy. Younger stands are vigorous (usually >15 to 20 years old); older stagnated stands (up to 100 years old) are also included; time since disturbance usually <40 years; up to 100+ years for dense (5,000–15,000+ stems per ha) stagnant stands.
6	Treed: Young Forest	Self-thinning has become evident and the forest canopy has begun to differentiate into distinct layers. A more open stand than at the pole/sapling stage.
7	Treed: Mature Forest	Trees established after the last stand-replacing disturbance have matured; a second cycle of shade-tolerant trees may have become established; shrub and herb understoreys become well developed as the canopy opens up.
8	Treed: Old Forest	Stands of old age with complex structure; patchy shrub and herb understoreys are typical; regeneration is usually of shade-tolerant species with a composition similar to the overstorey. Fire-maintained stands may have a single-storey appearance.
9	Treed: Very Old Forest	Very old stands with complex structures, abundant large trees, snags and coarse woody debris (CWD); snags and CWD occurring in all stages of decomposition; stands are comprised entirely of shade-tolerant overstorey species, with well-established canopy gaps.

3.2.2.2 Survey Methods

Three types of surveys assessed linear feature characteristics: ground surveys (finest level of detail), air surveys (medium level of detail), and air calls (coarsest level of detail). The reason for using different survey types was to maximize the sample size obtained, recognizing that the ability to collect certain types of data, or the level of measurement precision, decreased from ground surveys to aerial surveys to air calls. The characteristics that were measured during each survey type are noted in Table 3-1. Surveys were conducted between July 28 and August 8, 2019.

Ground surveys collected the most information and had the highest measurement precision of the three survey methods. All parameters listed in Table 3-1 were recorded. Field measurements generally followed methods in *Field Manual for Describing Terrestrial Ecosystems* (BC MFLNRORD and BC MOE 2010) with parameter specific details noted in Table 3-1. Photographs were taken of representative on-line and off-line plots.

Air surveys collected moderate resolution data on linear features. Air surveys efficiently collected a larger quantity of more generalized data than ground surveys. The subset of parameters recorded for aerial surveys is noted in Table 3-1. The survey methods generally followed procedures outlined for helicopter-based 'visual checks' in *Standard for Terrestrial Ecosystem Mapping in British Columbia* (Resources Inventory Committee 1998). Data were collected by hovering in a helicopter approximately 30 m over the sample sites for approximately three minutes while field crews recorded data for the reduced set of variables. Like ground surveys, relevant data were collected for both on-line and off-line plots. Photographs were taken at representative air survey plots (Attachment A).

Air calls collected data at the coarsest resolution of the three survey types, and no off-line data were collected. The data collected during air calls were limited to linear feature type, successional class, and burn status. Air calls were opportunistically conducted when EDI crews were flying through the RSA and linear features were encountered.

A fundamental aspect of the field study was to compare linear feature characteristics to adjacent undisturbed areas. Hence, field surveys included paired on-line and off-line plots at each sample site (excluding sites assessed via air calls). Off-line plots were located 50 m off the linear feature, with the direction off the feature selected randomly at each site using a coin toss. Data collected for each sample site were recorded on tailored survey forms (Attachment B).

3.2.2.3 Line-of-Sight and Ease of Travel

In addition to the structural and vegetation measures noted above, line-of-site and ease-of-movement were assessed as functional characteristics of the linear features at each ground plot. The sightline, measured to the nearest metre, was calculated as the farthest line that could be sighted using a range finder at the height of 1.5 m off the ground. Two measurements were recorded, one in each direction along the linear feature. Sightline measurements were repeated using the same bearings in the off-line plot.

Ease of travel was assessed using a 'walk test,' as Keim et al. (2019a) described in a study assessing the functional recovery of linear features. They found that ease of travel, as measured by a walk test conducted by human researchers, positively correlated with the intensity of use by several wildlife species. One EDI crew member timed themselves to the nearest second for the walk test while walking an approximately 75 m transect, measured to the nearest metre using a hip chain. This walk test was repeated in both the on-line and off-line plots, the paired transects spaced in parallel, approximately 50 m apart. The same observer conducted both walk tests to minimize observer bias at each site.

3.3 VISIBILITY OF LINEAR FEATURES FROM THE DEMPSTER HIGHWAY

One of the management concerns associated with seismic exploration is that seismic lines create travel routes that humans use. The probability of human use of seismic lines to access the surrounding landscape likely increases if the seismic line is visible and accessible from roads. The intersections of seismic lines and winter roads with the Dempster Highway are the primary locations where this could originate. Driving surveys were conducted along the 47 km section of the Dempster Highway within the RSA to determine the number and

type of linear features that could be located and accessed by the public from the Dempster Highway. Two types of surveys were conducted: a blind search where the location of the linear features was unknown and a 'map search,' where the observers had a map of the linear features that showed where they occurred. Both surveys were conducted on August 8, 2019.

The blind search approximated the proportion and type of linear features that the public could locate and access without prior knowledge of their locations. An EDI field crew drove along Dempster Highway at 35 km/h and attempted to identify linear features by visual inspection alone, unaware of where they intersected the highway. When a linear feature was identified, the crew stopped to record the following parameters:

- linear feature type;
- sight line distance;
- evidence of human use;
- evidence of wildlife use; and
- potential for OHV passage.

Photographs were taken, and relevant comments were recorded for each linear feature intersection where applicable.

The map search was a targeted search designed to approximate the proportion and type of linear features the public could spot from the Dempster Highway with prior knowledge of their locations. Using a map of linear features present in the RSA, an EDI field crew drove along the Dempster Highway, slowing to 10 km/h and attempting to identify the linear features when passing a point where the map showed they intersected the highway. When a linear feature intersection was reached, the crew recorded whether the line was visible or not and the parameters listed above for the blind search where a line was detected.

3.4 WINTER TRACK SURVEY

An aerial survey was conducted to assess the relative frequency of use of different liner feature types by ungulates and humans in late winter (March 2020). The survey consisted of 11 transects spanning the width of the RSA. Three of the transects were established parallel to the Dempster Highway at 50 m, 1 km and 5 km off the highway. The remaining transects were spaced approximately 5 km apart across the remainder of the RSA.

Before the field survey, each transect was established in a GIS. Each intersection with a linear feature was given a unique identification point and used to generate a field form (i.e., with a row for each linear feature intersection). The field survey involved flying along each transect and recording the presence of ungulate tracks or human tracks (e.g., snowmobile tracks) at each linear feature that was traversed. Surveys were conducted via helicopter at approximately 70 km/h, 50 m above the ground, with one navigator/data recorder and one primary observer. The surveyors classified tracks to species and counted the number of unique tracks. However, overlapping tracks and dustings of new snow made track identification and counts uncertain in over

half the detections. Therefore, analyses defaulted to the simple presence/absence of ungulate tracks. The primary metric examined was the proportion of linear features with ungulate tracks.

The original survey plan was also to count tracks in undisturbed areas between linear features. However, tracks were so numerous that surveying the entire area between linear features would have required substantially reducing the aircraft speed. This would have reduced the number of transects that could have been surveyed. As a compromise, field crews subsampled the area between lines by surveying an approximate 200 m band of an undisturbed area adjacent to each linear feature.

In conjunction with winter fish habitat assessments, the transects were surveyed over six days (March 7–13, 2020). Each day, one or two transects were surveyed while transiting to/from the study area. No track-erasing snowfalls occurred during the survey period. Snow depths ranged from 65 to 80 cm.

3.5 DATA PREPARATION AND ANALYSIS

3.5.1 SPATIAL DATA

The project generated two primary spatial datasets — a point database corresponding to all field survey sites and the linear feature database. The Linear Feature Survey Point Database (ArcGIS point feature class) contains all location-specific (point coordinate) field data collected at sample sites in summer 2019. Several fields were added to this database based on calculations and spatial joins (e.g., year of linear feature establishment and most recent fire). Paired on-line and off-line plot data were recorded as part of the same sample site coordinate.

The Linear Feature Inventory (ArcGIS polyline feature class) is a compilation of all documented linear features within the RSA, verified by comparing the preliminary linear feature inventory to aerial and satellite imagery and ground-truthing results.

Several modifications were made to improve the accuracy and detail of the Linear Feature Inventory:

- Linear features were classified into the following categories:
  - 2D (historical seismic lines, typically >3m wide),
  - 3D5 (including 4–5 m wide 3D lines that were used for both seismic and local vehicle/equipment travel);
  - 3Dc (3 m wide 3D seismic conductor lines);
  - 3Dr (2 m wide 3D seismic receiver lines);
  - winter roads (any trails or limited use roads used by vehicle or equipment, generally wider than 5 m and often with an obviously curving path); and,
  - Dempster Highway.
- Overlapping features (within a 3 m tolerance) were addressed according to the following rules:

- If two linear features of the same or unknown age overlapped, the wider feature was saved and the narrower feature deleted.
- If two linear features of the same or unknown width overlapped, the more recent feature was saved and the older feature deleted.
- If a 3D line overlapped with a 2D line, both lines were saved. This is because the older 2D lines were often still evident on the landscape in some state of regeneration, as were the 3D lines. However, both were saved since it was unknown at what state each line was in (i.e., if the 2D line was still evident, or only the 3D line, or both in varying states of regeneration). This occurred for 33 km of linear features within the RSA.

The preliminary linear feature inventory within the RSA was compared against a recent high-resolution satellite or aerial imagery (generally, 0.5–1 m resolution) at a 1:10,000 (or finer) scale to verify the accuracy of the source data. Any features that were visibly offset from georeferenced imagery were corrected to match the imagery.

Some older (1960s and 1970s) 2D seismic lines included in the source databases did not appear in satellite imagery. These 2D lines were compared against the imagery along the length of the feature to search for any sign of linear disturbance and then cross-referenced with field surveys conducted along the line, if present. These unverified linear features were classified as 'not applicable' and excluded from analysis if there was no evidence of linear disturbance along the feature's length in the imagery, which could often be verified with associated surveys noting that the feature was 'not present,' 'not visible,' or 'completely regenerated.' Unverified linear features were retained if there was evidence of linear disturbance along any feature's length in the imagery or if associated surveys had noted that the feature was present and in some state of regeneration, even if the feature was not visible in the imagery. A total of 199,473 m of erroneous or regenerated linear features were deleted from the linear feature inventory within the RSA.

Some linear features were visible on the imagery that had not been included in any of the source databases. In these cases, the linear features were manually digitized and classified into linear feature types based on visual assessment and attributes of adjacent connecting features, if present. Digitized linear features were assigned a year if they were obviously a continuation of a documented feature or if they were surrounded by features of the same type and year. Otherwise, the year was not included. High-resolution imagery was not available for the southernmost portion of the RSA (approximately 25 km by 15 km). This area was compared against lower quality Google Earth imagery, but this was not detailed enough to detect undocumented linear features if any existed (Google Earth 2019). However, existing linear features were verified using this method. A total of 202,945 m of linear features were digitized within the RSA.

After the Linear Feature Inventory was verified and corrected to be consistent with imagery and field observations, it was spatially joined to the Linear Feature Survey Point Database. In cases where the survey point did not correspond with any nearby linear feature, or if a linear feature was deleted (following the methods described above), the data were retained in the survey point database, but the linear feature type was updated to 'not applicable' and excluded from data analysis. Ten survey plots were identified as 'not applicable' and excluded from analyses; thus, the corrected sample size for survey plots is n = 210.

3.5.2 FIELD DATA

After completing field sampling, data forms and field notes were reviewed for completeness and accuracy during an internal data quality-assurance process. All associated digital photographs and GPS coordinates were reviewed to correspond to the appropriate field plots. A summary of field plots by linear feature type and survey type is provided in Table 3-4. All recorded data were entered into MS Excel databases (Microsoft 2019). Spatial data were uploaded to the ArcGIS platform (ESRI 2019).

Field-collected data were summarized primarily using Excel spreadsheets (Microsoft 2019). More detailed statistical analyses were performed on select data using R Statistical Software (R Development Core Team 2020). For example, the variation in ease of travel and vegetation cover as a function of linear feature types, burn history, successional stage, or ecosite were explored. During formal analyses, standard assumptions of normality and homogeneity of variance were assessed, and variance-covariance structures were applied to model heterogeneity (of residuals) if required. For instance, the sightline distance (m) was fourth-root transformed to meet normality. In certain models, random effects were included to account for variance among different subjects. For example, observers were included as a random variable to account for observer bias (i.e., a random intercept model; package "nlme", Pinheiro et al. 2016). Corrected Akaike's Information Criteria (AICc) scores were used to compare sets of candidate models. Models with the lowest AICc score were selected because they yielded the best balance (parsimony) between explained variance and level of complexity.

Table 3-4. The number of sites surveyed using ground surveys, air surveys, and air calls for each linear feature type in the Eagle Plains RSA.

Linear Feature Type	Survey Type			
	Ground Survey	Air Survey	Air Call	Total
2D	31	32	44	107
3D-5m wide	5	0	0	5
3D-Conductor	26	3	0	29
3D-Receiver	23	1	0	24
Winter Road	18	17	8	43
Dempster Highway	2	0	0	2
Not Applicable	3	2	5	10
Total	108	55	57	220

3.5.3 LINEAR FEATURE DENSITY CALCULATION

Linear feature densities were calculated in two ways: (1) using the total linear feature extents, and (2) adjusting the extents to account for (a) lines through 'open' habitats, such as wetlands and recent burns, where the vegetation on the line did not differ from vegetation off the line, and (b) functionally recovered linear features such as 2D lines from the 1960s and 1970s that had advanced regenerated at least to the Tall Shrub structural stage. Adjustments were determined by intersecting the Linear Feature Inventory with a recently developed

Ecological Landscape Classification (ELC) map of the RSA (a companion Eagle Plains Project baseline report). The ELC map documented the type and structural stage of vegetation communities across the RSA. The extent of linear features in open habitats was determined by the lengths of linear features overlapping Low Shrub, Herb and Bryoid structural stages in the ELC maps. This includes seral habitats regenerating from burns and ecosystems that are maintained in those stages over time, such as wetlands and shrub-carrs. The extent of regenerated linear features was determined by integrating the proportion of regenerated lines observed from the field surveys (e.g., 61% for 2D lines) with the length of lines through non-open vegetation types in the ELC map. Adjustments were applied to generate functional linear feature densities for each linear feature type individually (i.e., to compare the relative extents of different feature types) and combined to provide an overall density for all linear feature types. For example, the linear feature density for 2D lines was calculated by starting with the total length of 2D lines in the RSA, reducing that by the length of lines through open vegetation types, then reducing the remaining extent by the average proportion of 2D lines that were observed to be regenerated, and then dividing the remaining total length of lines by the extent of the RSA.

4 RESULTS

4.1 LINEAR FEATURE INVENTORY AND DENSITIES

A total of 4,269 km of linear features were mapped and verified in the RSA (Map 4-1, Table 4-1). Winter roads and 2D seismic occur in varying densities across much of the RSA. The extent of 3D seismic is limited to the one area straddling the Dempster Highway in the centre of the RSA.

The total linear feature density in the RSA was 1.79 km/km², based on a total length of 4,269 km and the RSA area of 2,386 km². 3D seismic lines accounted for approximately half of the total length of linear features in the RSA, 2D seismic lines accounted for about one-third, followed by winter roads and the Dempster Highway (Table 4-1). Adjusting for open habitats (i.e., areas in structural stages Low Shrub, Herb, and Bryoid) and vegetation regeneration[1] resulted in substantially lower densities of 0.52 km/km² (Table 4-2). Relatively large extents of recent wildfires were the greatest factor reducing linear feature densities. The relative proportions of the different linear feature types were similar after adjustments, though the proportion of 3D increased and 2D decreased. This was mainly due to the greater degree of vegetation regeneration on 2D lines, consistent with their age since disturbance.

Table 4-1. Summary of total length and density of linear features documented in the Eagle Plains RSA.

Linear Feature Type	Total Length (km)	The Proportion of Total Length	Linear Feature Density (km/km²)
2D	1,452	34%	0.608

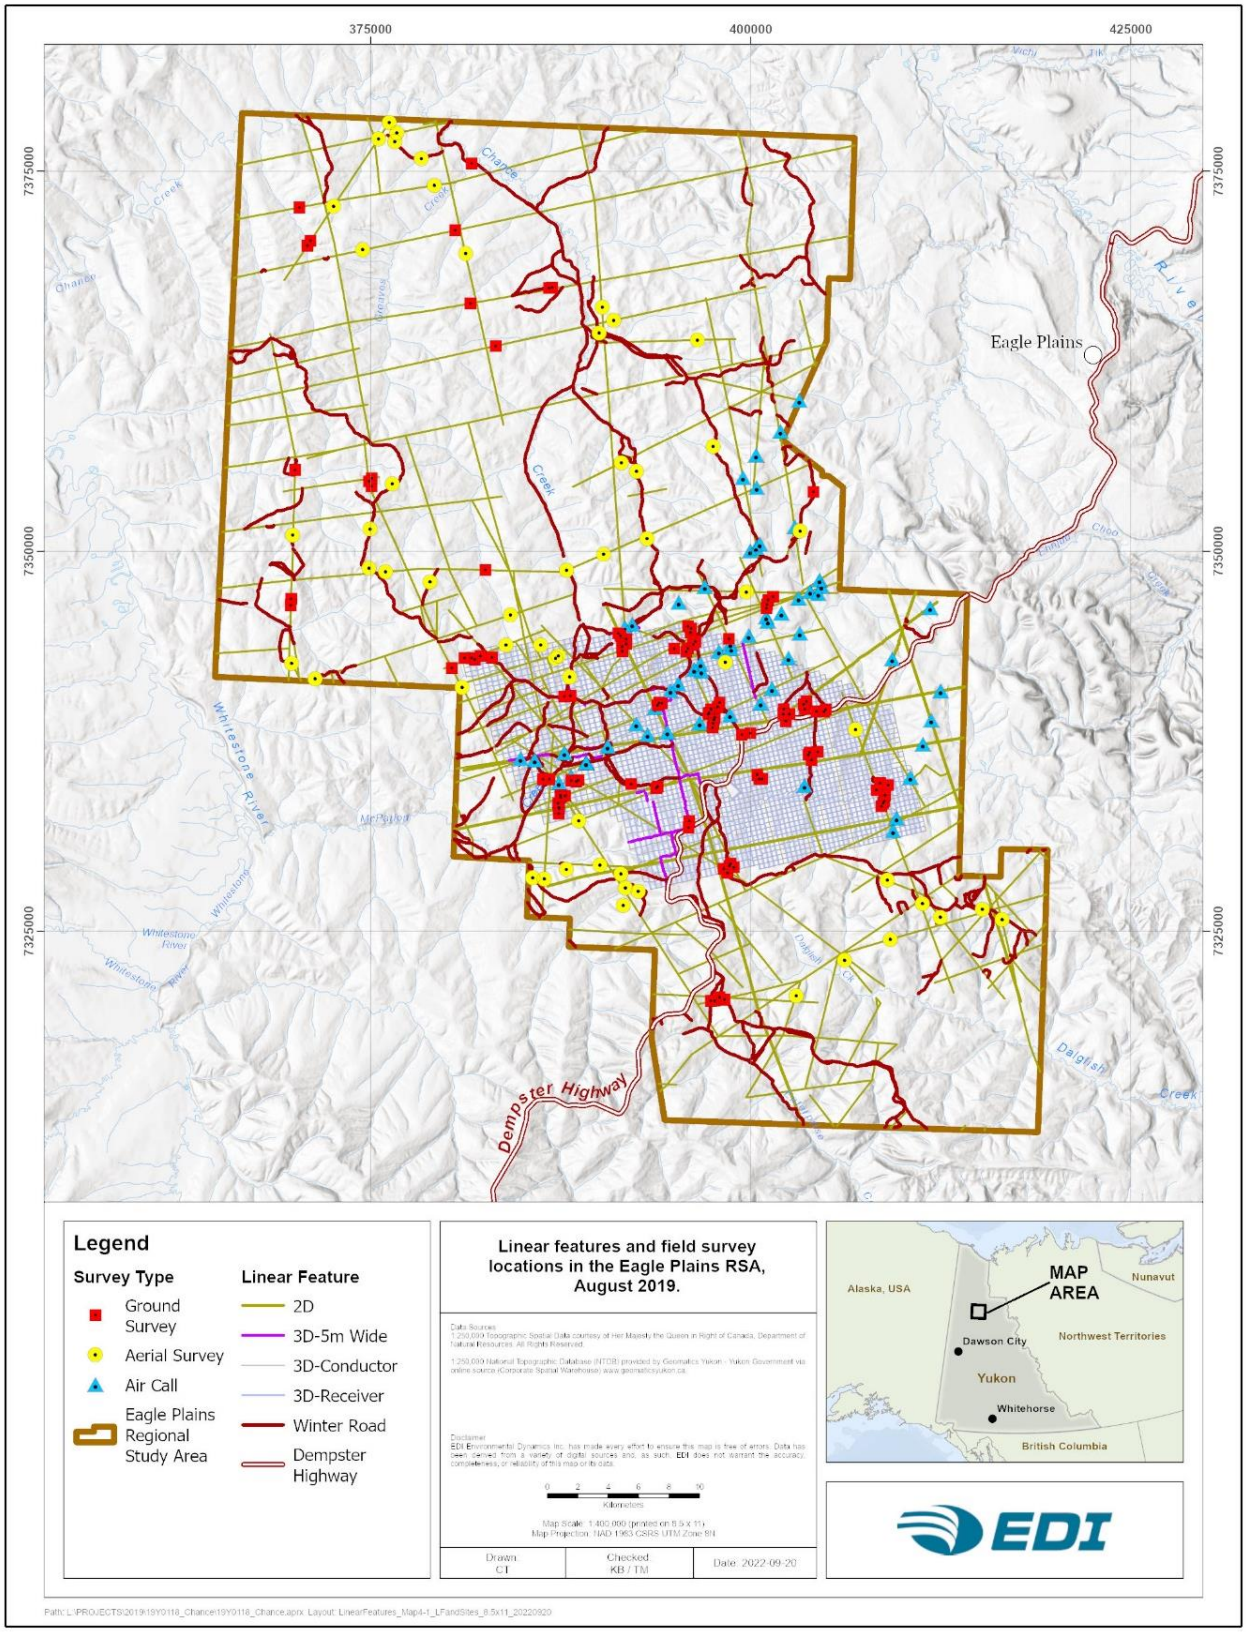

Map 4-1. Linear features and field survey locations in the Eagle Plains RSA, August 2019.

4.2 LINEAR FEATURE CHARACTERISTICS

4.2.1 LINE WIDTHS

Line width varied by linear feature type. Mean line widths ranged from 1.96 m for the narrowest line type (3D receiver lines) to 33.75 m for the Dempster Highway (Table 4-3). Standard error around mean estimates were smallest for 3D seismic lines, which were cleared in the same season using the same equipment and methods, and greatest (by a large margin) for winter roads. The average difference in widths between 3D conductor (wider) and 3D receiver lines was 1.2 m.

Table 4-3. Widths of different linear feature types in the Eagle Plains RSA.

Linear Feature Type	n	Minimum mean width (m)	Maximum mean width (m)	Overall mean width (m)	Standard Error (m)
2D	107	3.97	8.5	5.42	0.11
3D-5m wide	5	5.30	6.40	5.68	0.22
3D-Conductor	29	2.50	4.80	3.17	0.13
3D-Receiver	24	1.63	2.53	1.96	0.04
Winter Road	43	2.53	17.97	7.42	0.66
Dempster Highway	2	33.00	34.50	33.75	0.75

4.2.2 MULCH COVER

Mulching of woody vegetation is common during seismic line clearing activities and was used in the 2013/14 3D program. In areas with thick tree or shrub cover, mulching can create a thick blanket of wood chips that inhibits vegetation regeneration (Golder Associates 2016). There was no evidence that this was an issue with any of the seismic lines within the RSA. On average, the percent cover of mulch was <1% on all line types.

4.2.3 HUMAN USE

No sign of human use was detected along linear features during the summer ground surveys (e.g., OHV tracks, ruts, water crossings, vegetation trampling/scarring, tree blazes, trap sets, garbage, and campsites), except for the two sites on the Dempster Highway.

On average, 42% of on-line sites were deemed passable to an OHV (a 4x4 side-by-side) during summer, considering obstructing vegetation, ground conditions (e.g., wetlands or peatlands), and the presence of graminoid tussocks (Table 4-4).

Table 4-4. Proportion of survey sites deemed passable to OHV in summer across different linear feature types in the Eagle Plains RSA.

Linear Feature Type	No. Survey Sites	% Passable
2D	55	9%
3D-5m wide	5	80%
3D-Conductor	29	59%
3D-Receiver	24	75%
Winter Road	29	55%
Dempster Highway	2	100%
Total	144	42%

4.2.4 SUCCESSIONAL CLASSES

Linear features surveys in the Eagle Plains RSA observed five of the six of the successional classes documented by Simpson (2008): normal succession, magnified succession, stagnated succession, no succession, and recent disturbance (Figure 4-1) (Attachment A). No retrogressive succession sites were observed at official survey sites. However, a small number of retrogressive sites were incidentally observed on winter roads while travelling through the RSA.

Most sites surveyed (79%) were undergoing normal succession. The next most common successional class was magnified succession, occurring in 11% of sites, followed by stagnated succession, occurring in 5% of sites. All 3D seismic lines surveyed followed a normal successional trajectory, except for one site that was classed as recently disturbed. Magnified succession was most common in 2D seismic lines (21%), while stagnated succession was most common in winter roads (19%). Successional classes were defined as 'not present' if the linear feature was not present in the field or had regenerated to a stage that was not discernable from the adjacent areas. The Dempster Highway was classified as recently disturbed due to the regular maintenance of the road.

Fire history appeared to influence some successional classes. Magnified succession was more common at burnt sites (19 burnt versus 5 unburnt). In contrast, stagnated succession was more common at unburnt sites (3 burnt versus 7 unburnt). Sites on a normal successional trajectory did not appear to have any relationship to burnt status. The remaining successional classes were too uncommon to draw any conclusions.

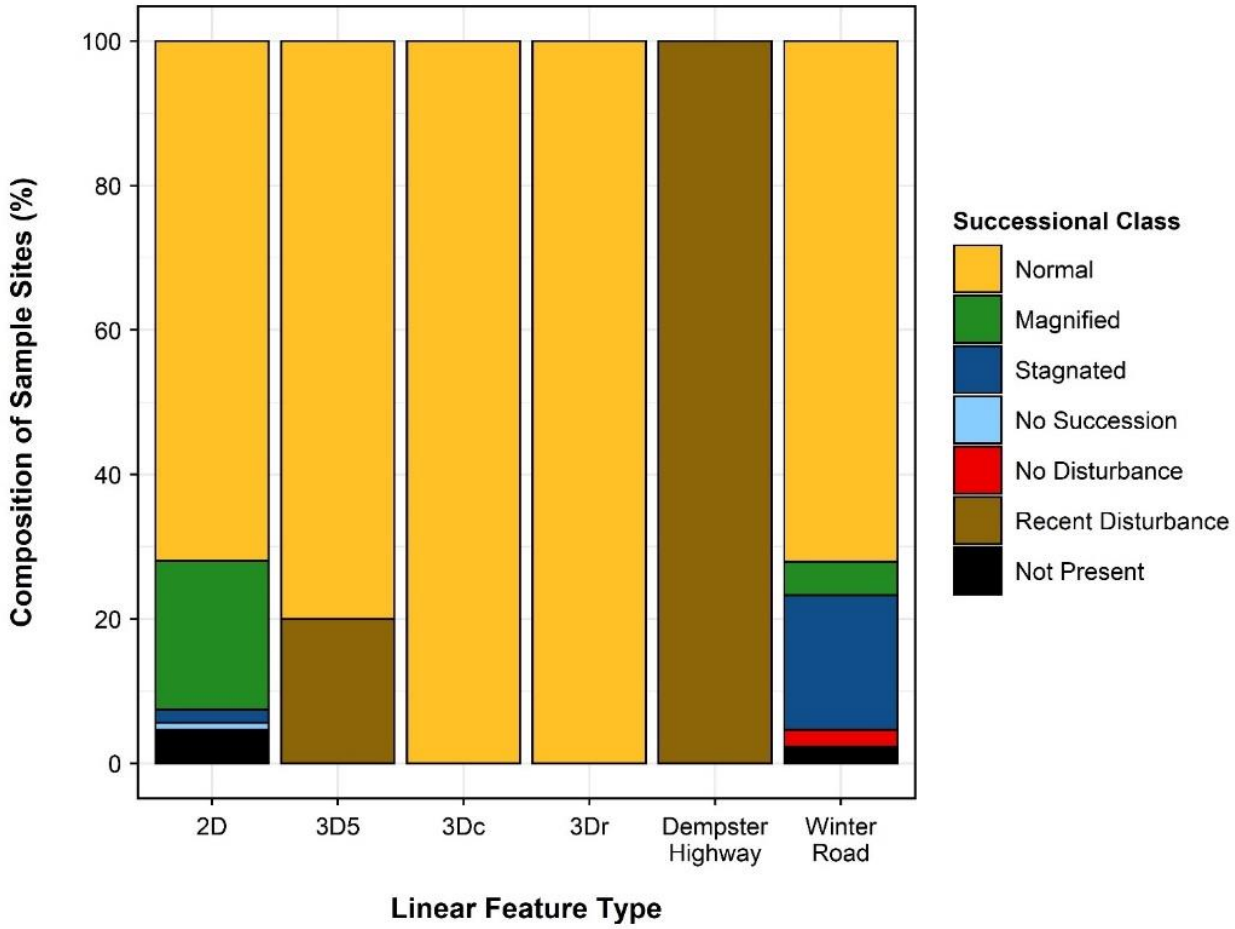

Figure 4-1. Summary of successional classes observed across different linear feature types in the Eagle Plains RSA.

4.2.5 STRUCTURAL STAGE

Most linear features were in a Low Shrub (56.1%) or Tall Shrub (29.0%) structural stage. However, the distribution of structural stages varied substantially across linear feature types (Table 4-5). Although herbaceous and forested stages occurred at some on-line plots, they were not common (less than 5%each). Nearly all forested structural stages were observed on 2D seismic lines and winter roads, reflecting the long time since they were created. Tall Shrub stages were almost twice as frequent in 2D seismic lines than any other linear feature type. Conversely, 83% of 3D linear features were in the Low Shrub structural stage, with most of the remaining in the Tall Shrub stage. The differences in structural stages between 2D and 3D lines appear to be primarily due to the time since disturbance. Winter roads were less consistent in their structural stages; herbaceous, shrubland and forested stages were all observed with moderate frequency. The two Dempster Highway plots were the only non-vegetated stages recorded.

Off-line plots were also mostly in Low Shrub and Tall Shrub stage, but they also included a higher proportion of Young Forest and Mature Forest compared to on-line plots (Table 4-5; Photos A-15 to A-20 in

Attachment A). For off-line plots, the Low Shrub sites were mostly burned areas, and the Tall Shrub sites were mostly stunted, open-canopy, black spruce forest 2–8 m tall.

Fire had a strong effect when comparing structural stages between paired on-line and off-line plots (Figure 4-2). The top two charts in Figure 4-2 show that the pattern of structural stages for burnt areas was very similar between on-line and offline plots. The bottom two charts show that the pattern of structural stages differs substantially between on-line and offline plots in unburnt areas. In unburnt areas, off-line plots had much lower numbers of sites in Low Shrub and much higher numbers of sites in Young Forest and Mature Forest than on-line plots. For burnt areas, the on-line and off-line plots at the same site were the same structural stage in 72% of cases, and within one structural stage of each other 91% of the time (e.g., Tall Shrub vs Pole Sapling). For areas that were not burnt, the on-line and off-line plots at the same site were the same structural stage in only 29% of cases. These results demonstrate that in the absence of fire, pronounced differences between linear disturbances and the surrounding community are evident in both recent (3D) and legacy (2D and winter road) linear feature types. But following a fire, the vegetation structure on-line and off-line are likely to be similar (Photos A-22 to A-24 in Attachment A).

Table 4-5. Vegetation structural stages observed on different linear feature types as a proportion of all plots sampled (n = 156) in the Eagle Plains RSA.

Linear Feature Type	No. Sites	Structural Stage[1]								
		Non-vegetated	Bryoid	Herb	Low Shrub	Tall Shrub	Pole-Sapling	Young forest	Mature forest	Old Forest
2D	62	0%	0%	2%	37%	47%	2%	8%	3%	2%

[1] See Table 3-3 for structural stage codes and descriptions.

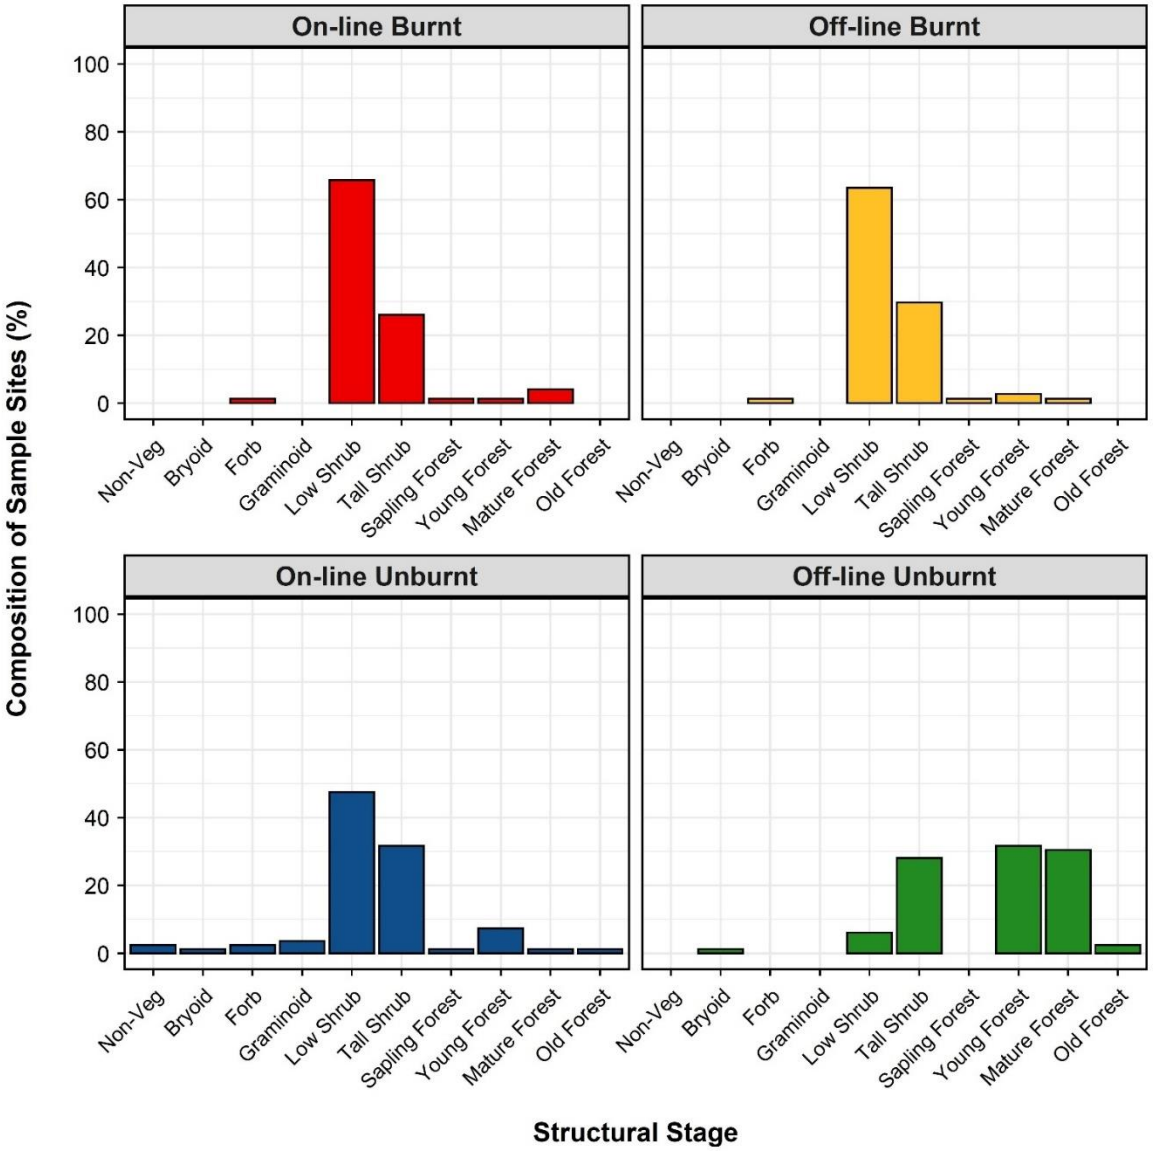

Figure 4-2. Comparison of structural stages on linear features to off-line plots in burnt and unburnt areas, in the Eagle Plains RSA.

4.2.6 VEGETATION HEIGHT

Based on the similarity of patterns in vegetation composition and structure, linear feature types were combined into two groups for assessment of patterns in height: (i) 2D and winter roads and (ii) 3D. A wide range of vegetation heights was recorded at both on-line and off-line plots in the RSA, from 0.3 m to 16 m. Collectively, off-line plots had a normal distribution of vegetation heights between 0 m and 4 m, and then a scattered distribution across heights up to 16 m (Figure 4-3). Plots with ≥4 m tall vegetation accounted for approximately 40% of all off-line reference plots.

In comparison, recovering 2D seismic lines and winter roads shared a relatively uniform distribution between 0 m and 4 m but with a peak occurring at vegetation heights measuring 1.5–2 m tall (Figure 4-4). Only 21% of 2D and winter roads contained dominant vegetation ≥4 m, and only 5% were ≥8 m tall. 3D seismic lines were rarely composed of vegetation ≥2 m, and most of the vegetation (67%) recovering on 3D lines was less than 1 m (Figure 4-5). This is very different from the off-line undisturbed height distribution. However, 3D lines were all only five years old at sampling, and shorter vegetation was expected.

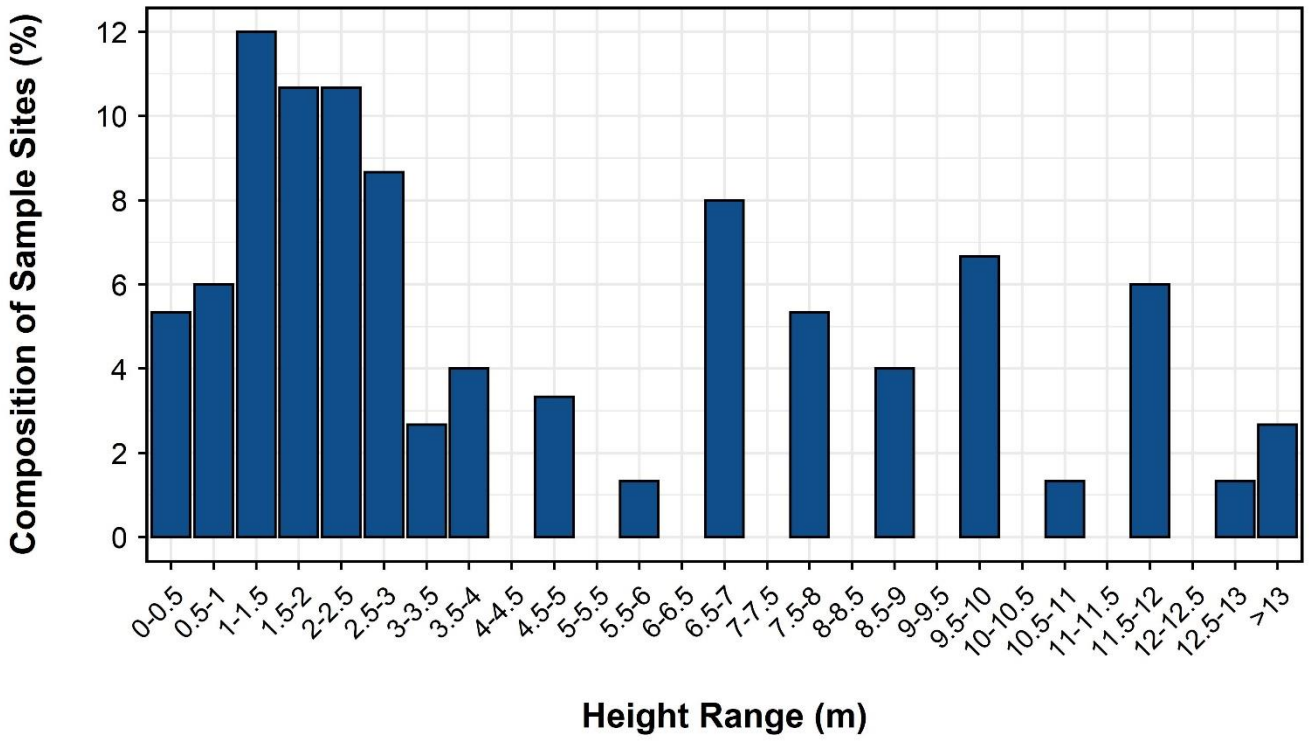

Figure 4-3. Vegetation height distribution of off-line reference plots in the Eagle Plains RSA.

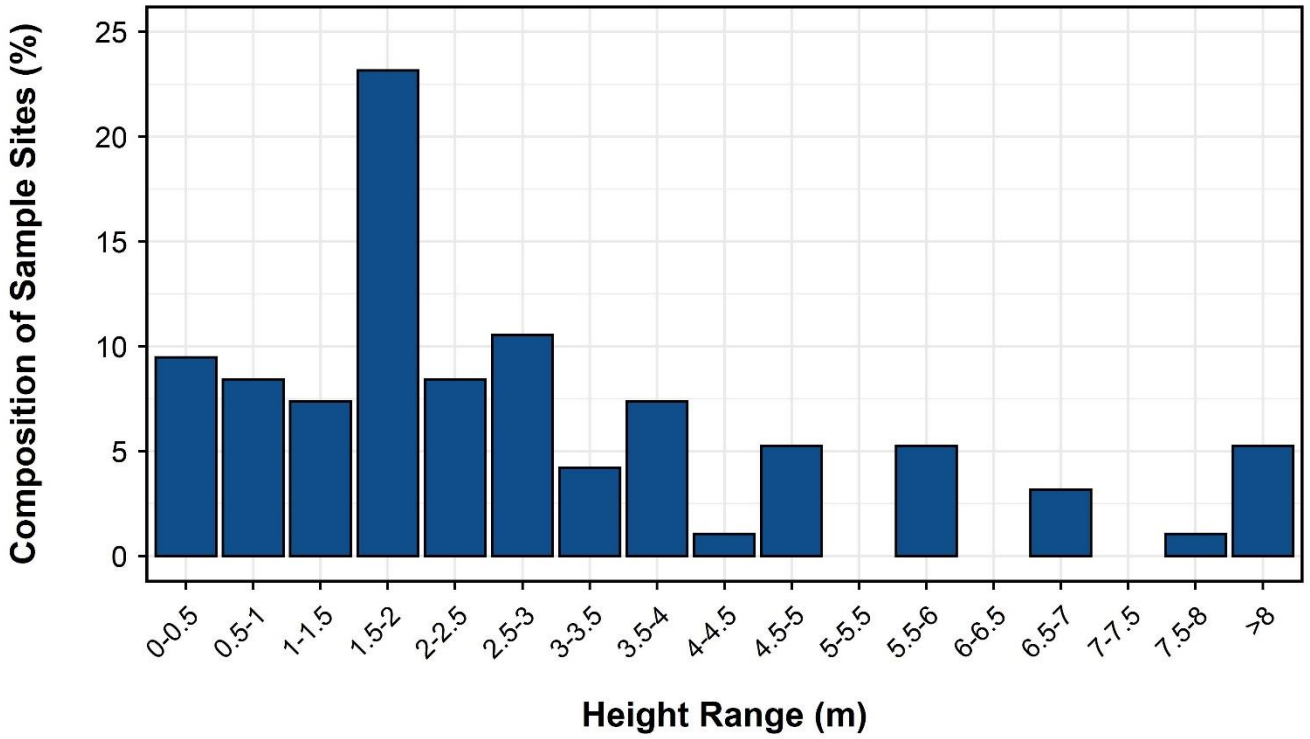

Figure 4-4. Vegetation height distribution of on-line 2D and winter road plots in the Eagle Plains RSA.

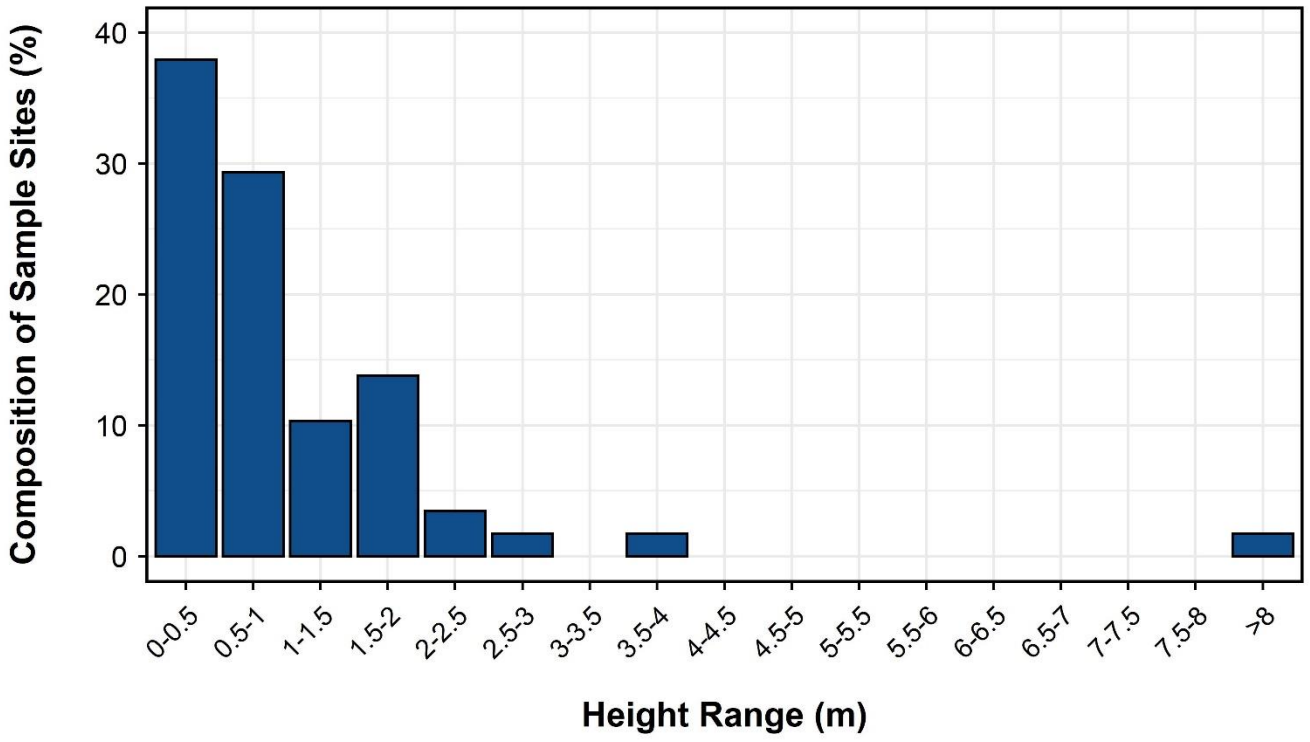

Figure 4-5. Vegetation height distribution of on-line 3D plots in the Eagle Plains RSA.

4.2.7 VEGETATION COVER

Tree and shrub cover varied between linear feature types and burn status (Table 4-6). Generally, tree cover was low on undisturbed reference plots (mean tree cover of 8% on unburnt and 2% on burnt sites). This is typical of the taiga cordillera landscape — forests are generally stunted and sparse due to poor nutrient regime and continuous permafrost conditions (Smith et al. 2004). Of the on-line plots, tree cover was greatest on 2D seismic lines and burnt winter roads (5% to 8%) and lowest on 3D seismic lines and the Dempster Highway (0%), regardless of burn status. This is likely due to the recently disturbed 3D seismic lines that are too young for trees to have re-established. Burnt 2D seismic lines and winter roads had greater tree cover than unburnt lines.

Shrub cover was much greater than tree cover overall. Shrub cover was typically 30–40% on unburnt off-line plots and 40–50% on burnt off-line plots. Shrub cover was highest on 2D seismic lines (~54%), regardless of burn status. Shrub cover was moderate on winter roads (38–45%) and lowest on unburnt 3D seismic lines (8–22%). Burnt 3D seismic lines had approximately twice as much shrub cover as unburnt 3D lines.

Table 4-6. Summary of the mean tree and shrub cover (%) between on-line and off-line, and burnt and unburnt plots surveyed in the Eagle Plains RSA.

Linear Feature Type	Burn Status	Mean Tree Cover (%)		Mean Shrub Cover (%)	
		On-line	Off-line	On-line	Off-line
2D	Burnt	7.0	3.5	54.0	36.0
	Unburnt	5.5	13.4	53.2	32.8
3D5	Burnt	0.0	0.3	41.7	60.0
	Unburnt	0.0	0.5	7.5	42.5
3Dc	Burnt	0.0	0.2	40.4	46.1
	Unburnt	0.4	6.0	21.5	34.3
3Dr	Burnt	0.0	0.7	35.0	51.9
	Unburnt	0.0	5.5	20.6	32.5
Winter Road	Burnt	7.7	1.0	45.0	43.8
	Unburnt	1.3	4.0	37.5	32.3
Dempster Highway	Unburnt	0.0	1.0	0.0	37.5

4.2.8 LINE-OF-SIGHT AND EASE OF TRAVEL

Line-of-sight (sightline) distance was examined primarily as a function of line type; however, vegetation height (the primary factor affecting sightlines) was also examined for on-line and off-line plots for each linear feature type using multiple linear regression. Mean sightlines varied significantly by linear feature type (Table 4-7, $F_{4,187} = 3.3$, $P = 0.01$). For reference, the average sightline distance for offline controls was 46.7 m. This relatively far distance reflects the open stand structure on most sites in the region. Burn status had little influence on sightlines (e.g., burnt off-line=50.2 m, unburnt offline=43.6 m). 2D lines had the shortest average sightline distances at 41.2 m. This was mainly due to the advanced stage of regenerating vegetation on the lines. Where regenerating vegetation was limited, sightline distances on 2D lines frequently exceeded 150 m.

On 3D lines, the time since clearing was too recent for regenerating vegetation to obscure sightlines. Instead, sightline distances on 3D lines were generally controlled by bends in the lines, which were specifically designed as mitigation measures to reduce sightlines. For 3D lines, sightline distances decreased from 3D5 to 3Dc to 3Dr lines. The reduction in sightline distances resulted from differences in line width and the average distance between bends across the feature types.

The regression analysis also found a significant interaction between on-line versus off-line occurrence and vegetation height ($F_{1,187}$ = 13.0, P = 0.0004), whereby on-line plots had, on average, more negative slopes than off-line plots. In other words, sightlines at on-line plots decreased more drastically than off-line plots with each incremental increase in vegetation height. This is consistent with the qualitative observations of field crews that the regenerating vegetation on lines was thicker than the vegetation off lines.

Similar to sightline distances, determining differences in ease of travel among line type the primary factor of interest for the walking speed tests. However, burn status, and the percent cover of trees and shrubs were expected to be the most important explanatory variables related to walk speeds, so they were included as secondary variables using a mixed-effects linear regression. Walking speeds across linear feature types and the differences between on- and off-line plots within linear feature types varied significantly (Table 4-8, $F_{5,170}$ = 3.4, P = 0.006). However, the magnitude of the difference between on-line and off-line plots was modest. Even the Dempster Highway only conveyed a 35% increase in walking speed over off-line plots. Other researchers, in other areas, often observed walk speeds on linear features were often at least twice as fast as off-line transects (Keim et al. 2019a).

Notwithstanding the modest magnitude of faster walking speeds on-lines, there were clear patterns in walking speed differences across linear feature types. 2D lines were the one feature type where walking speeds were slower on lines than off lines. This reflected the thick, shrub stage vegetation that had regenerated on most 2D lines, which impeded travel (similar to the effect that regenerating vegetation had on sightline distances in the previous section). Walk speeds decreased across the other feature types in relation to line width and the degree to which ground cover was levelled or compacted.

Statistical analyses indicated that both burn status ($F_{1,170}$ = 17.85, P < 0.0001) and percent cover of shrubs and trees (hereafter woody vegetation; $F_{5,170}$ = 5.29, P = 0.0002) affected walking speeds, both on and off lines. On average, walk speeds in burns were approximately 10% slower than in unburnt areas. This is partly related to thicker woody cover in most burns, which hinders walking speed because of the time it takes to push through or walk around it. Walking speeds significantly decreased, on average, by 0.04 (CI = 0.02–0.06) km/h and with every 10% increase in the percent of woody cover off-line and 0. 11 (0.07–0. 15) km/h on 2D lines.

Table 4-7. Average sightline distances along different linear feature types in the Eagle Plains RSA.

Linear Feature Type	n	Average Sightline Distance (m)	Comments
2D	30	41.2	Sightlines are frequently reduced by regenerating vegetation >1.5m tall
3D-5m	5	105.6	Has fewer bends than 3Dc and 3Dr
3D-Conductor	26	75.9	Sightlines limited by bends in lines; too recent for regenerating vegetation to impede sightlines
3D-Receiver	23	60.2	Sightlines limited by bends in lines; too recent for regenerating vegetation to impede sightlines
Dempster Highway	2	814.8	
Winter Road	17	106.2	
Off-Line Controls	103	46.7	

Table 4-8. Differences in walking speeds among linear feature types in the Eagle Plains RSA.

Linear Feature Type	n	Average Walk Speeds (km/h)		Difference (%)
		On-line	Off-line

Dempster Highway	2	5.6	4.1	35%
Winter Road	16	3.6	3.1	17%
Off-Line Controls	97	n/a	2.9	

4.3 VISIBILITY OF LINEAR FEATURES FROM THE DEMPSTER HIGHWAY

Overall, the blind search identified 11 of 100 possible linear feature intersections with the Dempster Highway (Table 4-9). Five of the features were roads that were classified as winter roads in the GIS inventory, but most (four) were actually short, all-season roads leading to gravel pits or well sites. Two of the observed features were human truck/OHV trails that led to camp sites 100–200 m off the Dempster Highway, and four were 3D seismic lines. The map search detected two more 3D lines, one 2D line, and one old winter road. The 2D line and the old winter road had regenerated into Young Forest structural stages. Excluding the four short secondary roads into gravel pits and well sites, and the two human trails, only 8% of linear features that intersected the Dempster Highway were visible during the two driving surveys.

Only 6 of the 74 3D lines that crossed the Dempster were detected. The combination of construction design (i.e., creating a bend in the 3D line adjacent to the highway) and regenerating vegetation in the right-of-way made it difficult to detect the 3D lines. Evidence of human use (e.g., packed vegetation, tire tracks, rutting, garbage, campfire remnants, tree stumps, or tree blazes) was observed on four of the short, all-season roads

and the two trails. No evidence of human use was noted on any of the 2D or 3D seismic lines, or the three winter roads (including the Chance and Blackie winter roads). However, some types of human use do not leave sign during the snow-free season (e.g., snowmobile use in the winter).

Table 4-9. Summary of linear features identified and intersecting the Dempster Highway during a blind search test.

Linear Feature Type	No. Features Intersecting the Dempster	No. (%) Observed Blind Search	No. (%) Observed Map Search	Total No. (%) Observed	OHV Accessible	Sign of Human Use
2D	18	0 (0%)	1 (6%)	1 (6%)	0	0
3D	74	4 (5%)	2 (5%)	6 (8%)	4	0
Secondary Roads	8	5 (63%)	1 (13%)	6 (75%)	5	4
Trail	n/a	2 (n/a)		2	2	2
Total	100	11 (11%)	4 (4%)	15 (15%)	11	6

4.4 WINTER TRACKS

In total, 462 linear features were surveyed for winter tracks over 358 km along the 11 transects. No human sign was observed on any linear features, except the Dempster Highway. Ungulate tracks were frequently observed travelling along linear features. The proportion of linear features with tracks decreased with decreasing linear feature widths, from 29% on winter roads, 24% on 2D lines, 8% on 3D conductor lines, and 6% on 3D receiver lines (Figure 4-6).

The frequency of use in adjacent undisturbed areas, corrected to account for different survey extents between the linear features and the undisturbed areas, was 1%. As discussed in the methods, it was difficult to compare the frequency of use along linear features to use in undisturbed areas. The issue is that for the comparison to be relevant, the survey design needs to account for the size of the sample units (i.e., the extent of the undisturbed area needs to be comparable to the width of the linear features), and the two samples should be independent. These conditions were not achieved under the current survey design (i.e., the extent of the survey area in the undisturbed area was much larger than the width of the linear feature, and the location of the undisturbed area was spatially correlated to the linear feature). The estimated relative use rate of 1% in undisturbed areas adjusts the total counts within the 200 m survey area to 5 m (i.e., the average linear feature width); however, the adjustment fails to account for spatial correlation between the two samples. Therefore, the estimate of use in undisturbed areas could be biased. Notwithstanding this limitation in the estimate of travel rates in undisturbed areas, it is supported by qualitative observations of the survey crew that travel rates on even the least used linear features (i.e., 3D lines) are higher than undisturbed areas.

The relative use of linear features by ungulates also appeared to vary with distance from the Dempster Highway, with features within 1 km of the highway receiving lower use than features equal to or greater than 5 km from the highway (Figure 4-7). It is worth noting that the Highway and 1 km transects were completed on the first and second day of surveys, respectively, and the other transects were surveyed one to six days later, providing more time for tracks to accumulate. Snowfall data prior to the crew's arrival on site was not

available; however, road crews at Eagle Plains reported that there had not been a major snowfall in the area for at least a week. Based on this information, the issue of time since last snow has less potential to bias results than if a track-erasing snow event had recently occurred.

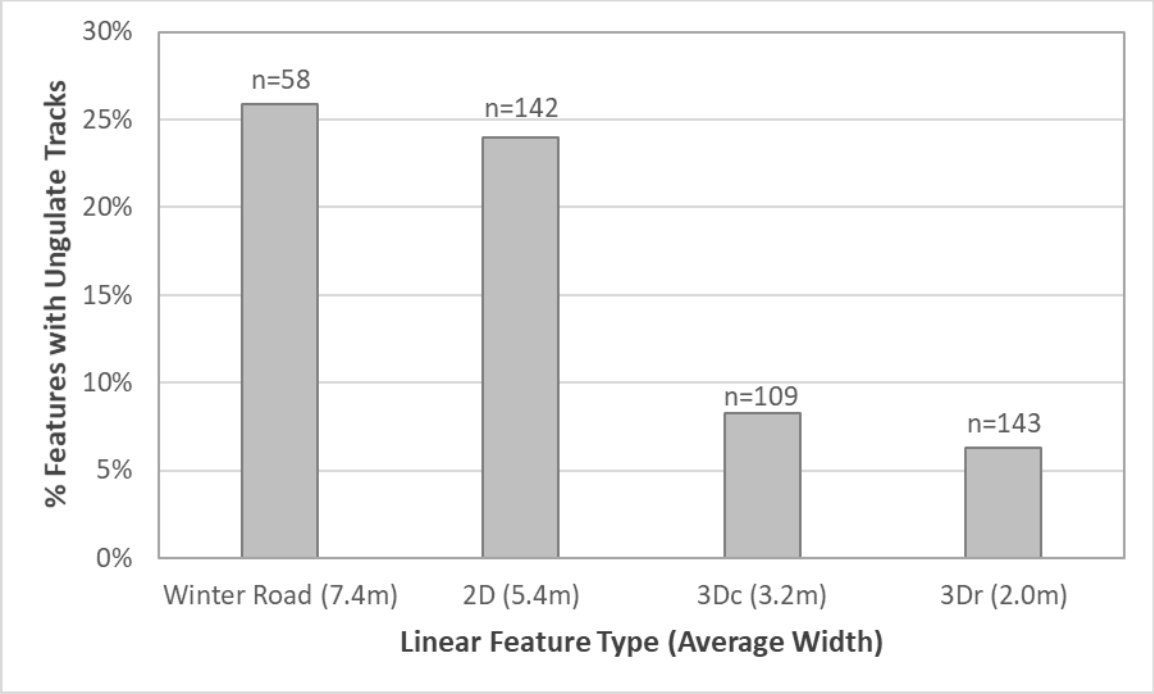

Figure 4-6. Relative use of different linear feature types by ungulates in the Eagle Plains RSA, March 2020.
The numbers above bars indicate the number of features surveyed.

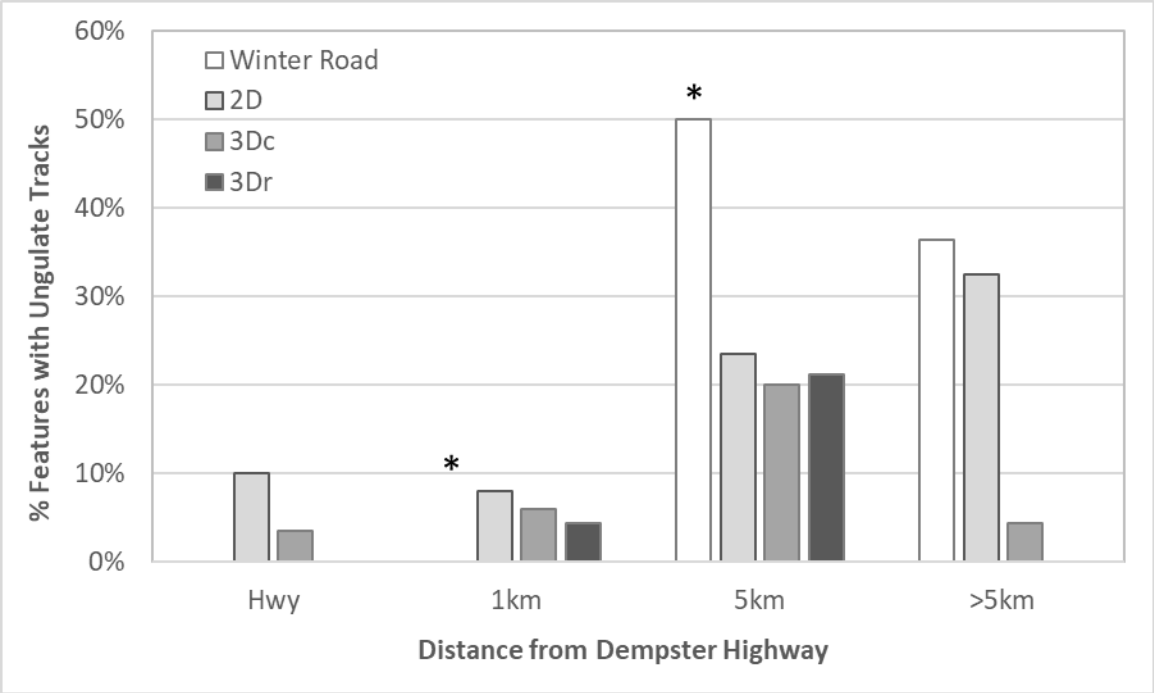

Figure 4-7. Relative use of different linear feature types by ungulates in relation to distance from the Dempster Highway in the Eagle Plains RSA, March 2020.

*The * indicates bars with small samples sizes (n=5-10); all other instances have at least 10 data points per feature type within each distance class*

5 DISCUSSION

5.1 SUMMARY OF LINEAR FEATURES IN THE EAGLE PLAINS RSA

Table 5-1 summarizes key characteristics across linear feature types in the Eagle Plains RSA.

Table 5-1. Summary of structural, ecological and functional characteristics of linear feature types in the Eagle Plains RSA.

Linear Feature Type	Mean Width (m)	Mean Sightlines (m)	Mean Movement Speed (km/h)	% Regenerated[1]	% Inhibited Regeneration[2]	Linear Feature Density (km/km²)	Adjusted Linear Feature Density (km/km²)[3]	% Ungulate Use[4]
3D seismic	2.6	71.98	3.36	14	0	0.91	0.31	7
2D seismic	5.4	41.17	2.53	61	4	0.61	0.12	24
Winter Roads	7.4	106.18	3.58	39	19	0.25	0.07	26

Off-line Controls	N/A	46.67	2.95	N/A	N/A	N/A	N/A	N/S

[1] as characterized by reaching a tall shrub stage, or greater.
[2] including stagnated and disturbed successional patterns.
[3] accounting for burns, natural openings, and regeneration.
[4] percent of lines with ungulate tracks during March 2020.

2D Seismic — 2D lines are, on average, the oldest features in the area and have had the longest time to regenerate. Most features were cleared before 1985, but some were developed in the early 2000s. Historical 2D lines were generally long and straight, with moderate widths of 4–8 m. Lines were typically constructed with bulldozers that cut into the moss layer and often included some patches of soil disturbance. The combination of site disturbance and wider widths generally resulted in a successional reset to pioneering vegetation (including early seral graminoids, forbs, and shrubs). Most sites were following a normal successional pathway (73%). However, 27% of sites exhibited atypical pathways, dominated by magnified succession (21%, mostly in burns), stagnated succession (3%) or no succession (1%). Sixty-one percent of the 2D sites had regenerated to a Tall Shrub or more advanced structural stage. 2D lines had the shortest sightlines and slowest walk test speeds of all feature types (including off-line controls), reflecting the regenerating vegetation's effect on these functional metrics. During winter, ungulates regularly used 2D lines to travel along.

3D Seismic — All 3D lines were created during the last exploration period, during the winter of 2013/14. 3D lines constitute the most extensive combined lengths of the different linear feature types, but their areal extent is limited to a relatively small portion of the RSA along the Dempster Highway. Due to their basic design, as well as specific mitigations, 3D lines minimize environmental effects compared to other linear feature types. They are narrow (averaging 3.2 m and 2.0 m for conductor and receiver, respectively), often

narrower than average tree spacing in the region. They were constructed during winter, over snow, using low-ground pressure equipment, which avoids ground disturbance and maintains vegetation in the moss, herb and low shrub layers. The lines were constructed with a meandering path, and strategically placed sharp angle dogleg bends to reduce the visibility of the lines from roads, reduce sightlines along them, and hamper travel by OHVs. All 3D lines that were surveyed were undergoing a normal successional pathway and were dominated by the same vegetation as in adjacent undisturbed areas. Regenerating vegetation was mostly in a Low Shrub structural stage, consistent with the relatively short six-year period since they were cleared. Sightlines and movement speeds were intermediate compared to other linear feature types, with sightlines primarily controlled by dogleg bends purposely designed to reduce sightline distances. Ungulates occasionally used 3D lines to travel on in winter, but at less than a third of the rate as 2D lines and winter roads.

Winter Roads — A network of winter roads across much of the RSA results from the historical exploration programs that have occurred. Although many of the winter roads were initially developed during the earliest exploration programs, vegetation has not had the same opportunity to regenerate as on 2D lines because the vegetation was re-cleared on several roads during subsequent exploration programs. The average width of winter roads was 7.4 m, but major roads, like the Chance road, were often 10–12 m wide. Historical winter roads were typically cleared with a bulldozer, and then snow was packed and graded to create a road surface. Similar to historical 2D seismic, the combination of site disturbance and wider widths (i.e., that increases solar exposure) generally resulted in a successional reset to pioneering vegetation (including early seral graminoids, forbs, and shrubs). Most sites were following a normal successional pathway (72%), but 26% of sites exhibited atypical pathways, dominated by stagnated succession (19%), magnified succession (6%) and no succession (1%); 2% of the sites were classified as no disturbance (indistinguishable from vegetation community off the road). Thirty-nine percent of the winter road sites had regenerated to a Tall Shrub or older structural stages. Winter roads had the longest sightlines and fastest walk test speeds of all feature types, other than the Dempster Highway, reflecting the variable levels of regenerating vegetation that occurred on winter roads. During winter, ungulates regularly used 2D lines for travel.

Dempster Highway — The Dempster Highway is the only all-season road in the RSA (except for short spurs off the Dempster to well sites and gravel pits). It is fundamentally different from all other linear features in the area in terms of wide width, surface material and maintenance, long sightlines, regular traffic, and base of access for human land use activities such as hunting, camping, and trapping.

5.2 LINEAR FEATURE CHARACTERISTICS

5.2.1 FIRE

The presence or absence of recent forest fires affected several linear feature characteristics, including linear feature width, successional class, structural stage, and vegetation height and cover. Mean measured linear features widths were 0.2–0.6 m wider at burnt sites than at unburnt sites. This may be due to the already shorter vegetation at burnt sites, which would reduce overgrowth occurring from forest edges and decrease the measured width between driplines (branches extending into the linear feature from either side of the line).

Magnified succession was nearly four times more common in burnt plots than unburnt plots, and stagnated succession was half as common. Fire likely facilitates magnified succession by increasing soil temperatures, accelerating decomposition, and releasing stored water and nutrients to promote vegetation growth (Seccombe-Hett and Walker-Larsen 2004, Simpson 2008). Stagnated succession is likely less common at burnt sites because the associated nutrient and water increase allows woody plant species to colonize more easily and advance through successional stages.

Overall structural stage distribution was very similar between burnt on-line and off-line plots, but was markedly different between unburnt on-line and off-line plots. Furthermore, when the structural stages were compared between paired on-line and off-line plots, they matched two to four times more frequently at burnt sites than at unburnt sites and were mismatched two to six more frequently at unburnt sites than at burnt sites. Nearly all burnt plots were in a low shrub, or tall shrub structural stage, which is expected as fires tend to remove overstory trees, and shrubs generally colonize rapidly post-fire (Seccombe-Hett and Walker-Larsen 2004).

Vegetation height was 4.4 m shorter in burnt than unburnt reference plots, and tree cover was approximately 6% less. These modest differences reflect the stunted and open nature of the taiga forest. There was little change in vegetation height between burnt and unburnt linear features, likely because there were very few linear disturbances in a forested structural stage; most of them, even in unburnt conditions, were already in a shrub-dominated stage due to the clearing of trees. For shrub cover, except for 2D seismic lines, the mean was approximately 10% to 20% greater at burnt plots than at unburnt plots. The increase in shrub cover at burnt sites was most prominent in 3D seismic lines due to their comparatively lower pre-fire shrub cover.

Post-burn vegetation was, on average, shorter and shrubbier than unburnt off-line plots, but taller and shrubbier than unburnt on-line plots. Furthermore, burnt paired plots were more similar in vegetation characteristics than unburnt paired plots. This evidence supports the theory that forest fires in taiga ecosystems resets the landscape to some extent and effectively erase signs of anthropogenic disturbance (Seccombe-Hett and Walker-Larsen 2004, Simpson 2008). Forest fire in the taiga returns ecosystems to an early successional stage (i.e., low shrub) and synchronizes baseline biophysical conditions on a landscape scale, allowing previously disturbed and undisturbed areas to recover at equal rates, as has been documented by Seccombe-Hett and Walker-Larsen (2004). Thus, most linear features that have experienced forest fires no longer create different ecological conditions or functional disturbances than the surrounding landscape.

5.2.2 SUCCESSIONAL CLASS

The idea that vegetation regeneration on linear features could follow different successional trajectories came out of work by the Yukon Government in the early 2000s (Simpson 2008). That work described six successional trajectory classes observed in the Eagle Plains area. However, that study did not quantify the relative extents of linear features that followed the different trajectories. This study used the classes that the Yukon Government work developed and quantified the proportion of linear features in each successional class across a random sample of linear features.

Successional classes in the Eagle Plains RSA varied according to linear feature type and burn status. However, one of the key findings was that normal succession was the dominant trajectory observed for all linear features except the Dempster Highway. All 3D seismic lines followed a normal successional trajectory, except for one recently disturbed site. This was likely attributable to the low impact methods used in 3D line creation that minimize ground and vegetation disturbance, creating conditions more likely to result in a normal successional trajectory (Yukon Energy Mines and Resources 2006, Golder Associates 2016). Magnified and stagnated succession were only observed in 2D seismic lines and winter roads. These linear features were generally wider and were created using methods that cause greater disturbance to soils, hydrology, and vegetation, leading to these alternative successional trajectories (Simpson 2008, Jorgenson et al. 2010, Dabros et al. 2018). Magnified succession is unique among the classes in that it results in accelerated vegetation regeneration. Magnified succession was most common on burned 2D seismic lines where the combination of site disturbance associated with the 2D lines and fire is suspected of causing accelerated soil warming, moisture availability, and nutrient flush, which increase on-line vegetation growth (Simpson 2008). Successional stagnation was most common on unburnt winter roads. Stagnation tends to occur on features that have experienced ground disturbance or have been seeded to agronomic species, which may have happened on winter roads in the RSA (Simpson 2008). Repeated disturbance associated with multiple exploration programs over time may also limit successional advancement and contribute to successional stagnation (Lee and Boutin 2006, Jorgenson et al. 2010).

Although some alternative successional pathways were observed in this study, most linear features in the Eagle Plains RSA are following a normal successional trajectory. This implies that most of these disturbances will recover to an ecological condition like that of the surrounding community with adequate time.

5.2.3 STRUCTURAL STAGE

The taiga forest in Eagle Plains presents a unique situation where the Tall Shrub stage is applied to two very different stand conditions. One condition, the more traditional, is of regenerating stands following a natural or anthropogenic disturbance. In this setting, the vegetation consists of deciduous shrubs and 2–8 m tall, 10–30 years old trees. The stage is transitional, with the vegetation expected to advance to the Pole-Sapling stage over time. The second condition where the Tall Shrub stage is applied is to stunted, old, black spruce stands in a disclimax state. In this setting, the vegetation consists of open, stunted, black spruce stands that are typically ≥50 years old and 2–8 m tall. Stands in this condition are expected to remain in the same condition over time(i.e., a disclimax state). Structurally, the stunted black spruce trees function more like shrubs than trees. Both Tall Shrub conditions (referred to as disturbance and disclimax forms hereafter) are widespread across the RSA in off-line sites. Only the disturbance form was observed on linear features.

The structural stage on linear features was predominantly Low Shrub or Tall Shrub, determined mainly by the time since line clearing and burn status. Less than 4% of surveyed features were in forested stages (Pole-Sapling or greater). Off-line plots had a higher proportion of forested structural stages (37%). However, they were still predominantly Low Shrub and Tall Shrub, resulting from extensive burns across the RSA and large extents in the disclimax form for Tall Shrub in un-burned areas.

The structural stage of on-line plots was also influenced by successional class. The small number of forested structural stages observed on features only occurred on sites undergoing normal succession. Stagnated succession was associated with only the Herb structural stage, which was expected as stagnation is defined by its high herbaceous species cover (among other factors) that limits the establishment of other structural groups. Magnified succession was the one atypical successional class with accelerated vegetation growth. Most structural stages on sites with magnified succession were in Tall Shrub and, occasionally, Pole/Sapling. Often the structural stage on magnified succession sites was one stage greater than the off-line plot.

5.2.4 VEGETATION HEIGHT

This study observed a range of vegetation heights across different feature types. Except for the 3D lines, the linear features' age was unknown, so it was impossible to estimate growth rates. Although some regenerating vegetation on 2D seismic lines and winter roads reached 8 m high, most were between 1.5 m and 2 m. Though the ages of specific features were mostly unknown, the minimum age for most was at least 35 years. Having most vegetation heights at only 1.5–2.0 m after this long period suggests regeneration growth rates on linear features may be quite slow. This pattern of slow vegetation growth on linear features may partly reflect the generally poor growing conditions in the taiga region. Still, it is also a pattern that has been observed on linear features in other studies in the southern boreal forest.

Interestingly, the vegetation heights on linear features in Eagle Plains are greater than reported in several other studies. For example, approximately 65% of sites on linear features in northeast Alberta had not advanced beyond a cover low forbs after 35 years (Lee and Boutin 2006). Key factors that have been linked to slow vegetation regeneration on linear features were continued human disturbance (e.g., OHV travel), ecosystem type (bogs and fens regenerated much slower than upland sites), competition from early seral and invasive graminoids and forbs, and soil or site degradation associated with feature construction (Lee and Boutin 2006, van Rensen et al. 2015, Finnegan et al. 2018).

There is limited data on vegetation regeneration in the taiga. A study from NWT found that vegetation regeneration on conventional seismic lines was affected by both a time lag for seedling establishment (as long as 17 years for black spruce) and slow growth rates (83 years to reach 5 m) (Seccombe-Hett and Walker-Larsen 2004). In burned areas, the seedling establishment delay was reduced to five years.

Although the 3D lines in Eagle Plains were only six years old when they were surveyed, a combination of field survey results and information from other studies suggests that vegetation recovery on 3D lines could be much faster than the previous examples for conventional 2D lines. This is because the undisturbed ground conditions and maintenance of the vegetation community in the moss, forb and low shrub layer provide both plants and growing conditions that support faster shrub and tree growth compared to sites beginning primary succession. In northeast British Columbia, Golder Associates (2016) found that in the first year following 3D seismic line creation, there were already black spruce seedlings exceeding 0.5 m in height. These seedlings were plants that were initially present on the site and that had survived line clearing. This is consistent with the results of this study, where nearly all of the 3D plots contained black spruce seedlings. Despite their relatively young age, most 3D seismic lines in Eagle Plains included shrubs and trees between 0.5 m and 1 m

tall. Although growth rates in Eagle Plains are not known, similar species that occur in Eagle Plains were observed to grow 5–10 cm per year on 3D lines in the boreal forest in northeastern British Columbia (Golder Associates 2016). If similar growth rates occur in Eagle Plains, regeneration on the 3D lines can be 2 m over the next 5–20 years.

5.3 HUMAN USE AND ACCESS ALONG LINEAR FEATURES

The NYRLUP and the PWRLUP indicate that one of the primary concerns about linear features is that they can increase human access into remote areas. This has been demonstrated in southern regions, and that access can have secondary effects of inhibiting vegetation regeneration (Lee and Boutin 2006) and, in winter, packing snow that can affect predator-prey dynamics (Latham et al. 2011, McKenzie et al. 2012, Keim et al. 2019a). In the boreal forest in northern Alberta, OHV travel was common on most conventional 2D seismic lines. After 35 years, approximately 20% of the lines were considered to have been converted to tracked access routes (Lee and Boutin 2006). In the same study, about 65% of the lines remained cleared after 35 years, and OHV use along the lines was identified as one factor contributing to the lack of vegetation regeneration. In contrast, there is little evidence of human use along linear features in the Eagle Plains RSA. No sign of human use was detected along linear features during the summer ground surveys (e.g., OHV tracks, ruts, water crossings, vegetation trampling/scarring, tree blazes, trap sets, garbage, campsites, etc.) or the winter track survey (e.g., snowmobile tracks). Although these surveys provided limited snapshots in time, and that some types of human activity leave little sign (e.g., evidence of snowmobile tracks have limited persistence during winter and leave no sign behind after snow melt), the results suggest that human use of the area is very limited outside of the Dempster Highway corridor. This is consistent with general comments from highway workers, staff at the Eagle Plains Hotel, pilots, and some First Nation residents that most areas beyond the Dempster Highway corridor receive very little human use. Specific instances of use of the area outside the Dempster Highway corridor include intermittent activity on the community trapline that occurs in Eagle Plains and occasional forays by hunters (First Nation and non-First Nation), mostly in winter.

People's limited use of the Eagle Plains area is likely due to its far distance from any human settlements and the difficulty of travel off the Dempster Highway. The network of winter roads in the area does provide access via specific types of OHVs in summer and snowmobiles in winter. However, there was no evidence observed that this occurs regularly. Travel along seismic lines, though possible in specific locations, would be hampered over any substantial distance by vegetation regeneration along the historical 2D lines, the narrow widths of and frequent dogleg bends in 3D lines and, during summer, difficult terrain (extensive peatlands and graminoid tussocks).

5.3.1 EFFECTIVENESS OF MITIGATION MEASURES FOR 3D SEISMIC LINES

In addition to the narrow widths of 3D lines, which hampers OHV travel, the 3D lines included regular bends in the lines, which were designed to limit the visibility of the lines at intersections with roads and other seismic lines, and to hamper OHV along the lines further. The driving survey along the Dempster found that this mitigation was very effective in reducing the visibility of the 3D lines from the road (i.e., only 6 of the 74 3D

lines intersecting the Dempster Highway were visible). Incidental observations during ground surveys observed similarly reduced visibility of 3D lines crossing winter roads. Regular bends in the 3D lines away from roads were also designed to limit human access by reducing sightlines and making travel more difficult along the line (i.e., needing to reduce speed to navigate the tight turns of a dogleg bend approximately every 70 m).

5.4 FUNCTIONAL CHARACTERISTICS OF LINEAR FEATURES

In addition to human travel, linear features can also affect how wildlife move within a landscape. Several studies in western Canada have documented the effects of linear features on the movements and population dynamics of large mammals, such as caribou, moose, deer, wolves and bears (Latham et al. 2011, McKenzie et al. 2012, Dickie et al. 2017b, Keim et al. 2019a). EDI focused on two established indicators of human and wildlife access and travel on linear features: sightline distance and ease of travel. These measurements act as a proxy for the functional recovery of disturbed areas. They are mainly dependent on vegetation height, cover, and terrain.

5.4.1 LINE-OF-SIGHT

Line-of-sight or sightline distance is how far one can see under normal conditions and was compared between linear features and paired reference plots. It has been proposed that humans and predators select linear disturbances because it is easier to travel and detect prey using those features (Finnegan et al. 2018). As vegetation grows taller and denser, sightlines diminish, and the use of linear features decreases (e.g., for wolves, Dickie et al. 2017a). This study found that average sightlines were farther on-line versus off-line for most linear feature types, but that sightlines varied substantially across line types. Sightlines were shorter on seismic lines than on roads, especially 2D lines which had more advanced vegetation regeneration than other feature types. On 3D lines, sightlines averaged approximately 30 m farther on lines than off lines. However, this difference probably provides little advantage to predators or human hunters because the increase is still within the olfactory and auditory detection zone for most large prey species. Average sightlines were 60 m farther on winter roads than surrounding forest, which may begin to confer more advantage to predators and hunters.

The range of sightlines observed on most linear features probably do not provide an advantage to detect prey species visually. For 2D lines and winter roads, sightline distances were primarily driven by the height and density of regenerating vegetation. The recovery period for 2D seismic lines appears to be sufficient to support vegetation that reduces visibility to a similar level as the surrounding habitats. The reason for longer sightlines on winter roads is that they are subject to intermittent re-activation, where the vegetation is cleared once again, which resets vegetation recovery and maintains longer sightlines. In contrast to 2D lines and winter roads, where sightlines were largely determined by vegetation regeneration, the sightlines on 3D lines were presently limited by the bends purposely constructed into the lines. Sightlines along all feature types will continue to diminish over time as vegetation regeneration continues.

5.4.2 EASE OF TRAVEL

Ease of travel is a fundamental indicator of functional recovery of linear features. Wolves, bears, and humans have been documented to select linear features with greater ease of travel, which is generally associated with lower and more sparse vegetation and stable, even terrain (Dickie et al. 2017b, Keim et al. 2019a). Access and travel resistance are the main determinants of predator and human use of linear features and the key concern of linear disturbances in the RSA (Vuntut Gwitchin Government and Yukon Government 2009, Peel Watershed Planning Commission 2019).

The walk test used in this study, as an index of ease of travel, found differences among linear feature types and between linear features and controls. However, the magnitude of the differences for both comparisons was modest. Even the Dempster Highway only conveyed a 35% increase in walking speed over off-line plots. Other researchers, in other areas, often observed walk speeds on linear features were often at least twice as fast as off-line transects (Keim et al. 2019a). Two conditions associated with the Eagle Plains area appear to limit the advantage of travelling on linear features. One is that the vegetation in most ecosites and structural stages is relatively open and has a limited effect on impeding movement. The second factor is that ground conditions limiting movement, including soft, thick peat and graminoid tussocks, were similar on both on-line and off-line plots for most linear feature types.

Notwithstanding the modest magnitude of faster walking speeds on-lines, there were clear patterns in walking speed differences across linear feature types. 2D lines were the one feature type where walking speeds were slower on lines than off lines. This reflected the thick, shrub stage vegetation that had regenerated on most 2D lines, which impeded travel (similar to the effect that regenerating vegetation had on sightline distances in the previous section). Walk speeds decreased across the other feature types in relation to line width and the degree to which ground cover was levelled or compacted. 3D seismic lines allowed slightly easier travel than paired off-line plots. They usually had lower vegetation cover and clearer route selection. As linear feature width decreased in 3D lines, walking speed also decreased. This implies that width may be related to functional recovery, with narrower lines having smaller impacts than wider lines, even within an already narrow linear feature type. Although ease of travel was greater in 3D seismic lines than surrounding community, it is expected that this will decrease in future years as vegetation increases in height and density.

5.5 FUNCTIONAL RECOVERY OF LINEAR FEATURES

Functional disturbance is defined in the NYRLUP and PWRLUP as "*physical land use disturbance that results in disruption of soil or hydrology, or that requires the cutting of trees*." One of the main concerns with linear disturbances under these land use plans is that such features can technically allow increased access to previously remote areas, potentially leading to a greater harvest of wildlife and fish, higher predation rates, and a change in how people and wildlife use the land (Vuntut Gwitchin Government and Yukon Government 2009). A disturbance can be considered functionally recovered and subtracted from the overall linear density when it no longer facilitates access or travel by humans or wildlife (Vuntut Gwitchin Government and Yukon Government 2009), or otherwise no longer functions as a surface disturbance (Peel Watershed Planning Commission 2019). Both plans use 1.5 m vegetation height as a threshold for functional recovery in forested communities. The

PWRLUP includes the following additional criterion for recovery "*in non-forested areas (dominated by vegetation under 1.5 m), when the disturbed area is covered by native species roughly the same height and composition as the surrounding dominant vegetation*" (Peel Watershed Planning Commission 2019):

One limitation of using height alone as a functional recovery criterion is that it does not consider vegetation density. Although regeneration may meet the recommended height criteria, if it is very sparse (as is often the case in the Eagle Plains Ecoregion), it may still facilitate access and travel by humans and wildlife. Attachment Photo A-25 provides an example in the Eagle Plains RSA where tall but sparse regeneration meets the 1.5 m criteria but does not inhibit access or travel.

The combined results of this study indicate that using regeneration to the Tall Shrub structural stage may be a more appropriate criterion for functional recovery. Attachment Photo A-3 and Attachment Photo A-10 provide examples of linear features that have regenerated to a tall shrub structural stage. Using the Tall Shrub criterion, 38% of all linear features in the RSA would be considered functionally recovered compared to 53% using the 1.5 m height criterion. For this study, the more conservative criterion of reaching the Tall Shrub structural stage was used to adjust (reduce) linear feature densities.

5.6 LINEAR FEATURE INVENTORY AND DENSITY

This study was successful in mapping all linear features within the RSA. The combined results of the mapping exercise and the field studies found that the extent of open habitats (burns and naturally open habitats like wetlands and shrublands), and the degree of vegetation regeneration, played a significant role in the effective density of linear features across the RSA. Before accounting for open areas and regeneration, the total linear feature density was 1.79 km/km². After accounting for open areas and vegetation regeneration (to the Tall Shrub structural stage), the effective linear feature density was 0.52 km/km². The NYRLUP and PWRLUP suggest cautionary levels for linear density of 0.75 km/km² and critical levels of 1.0 km/km² (Vuntut Gwitchin Government and Yukon Government 2009, Peel Watershed Planning Commission 2019).

The Yukon Land Use Planning Council (YLUPC) was conducting a pilot study of surface disturbance across the broader Eagle Plains Ecoregion (Skinner 2021) at the same time as this study. The methods they used consisted of mapping and attributing human-caused disturbances solely using high-resolution satellite imagery. The YLUPC classified vegetation into eight broad classes based on whether the surrounding area was forested or non-forested, the similarity of vegetation on-line to off-line, and the presence or absence of woody cover (i.e., shrubs or trees). The features were then classified as recovered or not-recovered based on the presence of woody cover (recovered) or, if woody cover was not present, the similarity to surrounding vegetation (i.e., if similar then recovered, if not similar, then not-recovered). Historical field data and photographs from the area (Simpson 2008) were used to verify interpretations.

The spatial data from the YLUPC work was not available to compare in detail to the linear feature inventory compiled in this study. However, the mapping linework is expected to be very similar because satellite imagery was used to verify and supplement the linear feature geospatial data compiled in this study (presumably the same satellite imagery that YLUPC used because the imagery was obtained from Yukon Geomatics). One

difference between the two products is that the YLUPC completed the inventory for the entire Eagle Plains Ecoregion, while this study was restricted to the RSA. Another difference is that the attribute data in this study is expected to be more detailed and more precise than the YLUPC data because (i) the original geospatial data includes some information, like date of creation, that would be impossible to estimate from imagery, and (ii) because this study linked field surveys to the mapping exercise to determine line widths and other characteristics more precisely.

Although it is impossible to directly compare the linear feature density estimates between the two studies, due to the different study extents, the general pattern of results is similar. The YLUPC estimated the linear density (accounting for recovery) to be 0.38 km/km² across the entire Eagle Plains Ecoregion. This is consistent with the estimate from this study for the RSA of 0.52 km/km² because the portion of the Ecoregion outside the RSA has lower linear feature density than the RSA.

6 CONCLUSION

This study successfully mapped all linear features within the RSA and measured a suite of structural, vegetation, and functional characteristics across different feature types. Generally, the effects associated with linear features (i.e., differences between conditions on-line and adjacent off-line areas) correlated to feature width and the degree of ground disturbance. In terms of combined effects across the range of feature types that occur in the Eagle Plains RSA, the ranks were:

Dempster Highway >>> Winter Roads > 2D Seismic > 3D-5m >> 3D Conductor > 3D Receiver[2]

The effects of 3D lines (both conductor and receiver lines) appear to be substantially lower than other feature types. This reduced magnitude of effects is important because 3D lines have the longest combined length of exiting linear features. They are also the predominant feature planned for the next exploration program. Important findings for 3D lines include:

- Relatively narrow line widths of 2–3 m are often smaller than natural tree spacing and minimize the potential for changes to microsite conditions (e.g., solar radiation, air and ground moisture) reported in other studies.
- Minimal ground disturbance and maintenance of the moss, herb, and low shrub layers, which retains the natural vegetation community and accelerates vegetation regeneration.
- Successful application of mitigations, notably dogleg bends that minimize sightlines, ease of human travel, and visibility of lines from roads.
- Ungulate use of 3D lines in winter was less than a third of the rate observed on 2D lines and winter roads.

The adverse effects of linear features in other areas are often caused or exacerbated by human use after the lines are initially constructed, including effects on vegetation regeneration and predator-prey dynamics. Human use does not appear to be a significant factor in Eagle Plains. No sign of human use was observed outside the Dempster Highway corridor.

Substantial vegetation regeneration has occurred on existing features in the Eagle Plains RSA. Previous work by the Yukon Government identified the potential for atypical successional trajectories to occur on linear features in the region. Although atypical succession occurred to a limited extent, this study determined that 81% of the sites exhibited a normal succession (100% on 3D lines). Only 5% exhibited inhibited regeneration trajectories (mostly stagnated succession on winter roads). Regarding functional recovery, 53% of sites met the NYRLUP and PWRLUP criterion of vegetation reaching 1.5 m, and 38% of sites met the criterion of attaining a Tall Shrub structural stage. Using the Tall Shrub structural stage as a criterion of functional recovery may be a more ecologically appropriate criterion to meet LUP objectives.

The extent of open habitats (e.g., burns, wetlands and shrublands) and the degree of regeneration on existing linear features (mostly the older 2D lines and winter roads) play an important role in calculating effective linear

[2] Relative magnitudes of effects: >>> large effect, >> moderate effect, > small effect.

feature density in the RSA. Before accounting for open areas and regeneration, the total linear feature density was 1.79 km/km². After accounting for open areas and vegetation regeneration (to the Tall Shrub structural stage), the effective linear feature density was 0.52 km/km².

APPENDIX 2-A-06. November 6, 2018, Meeting Summary

First Nation of Na-cho Nyak Dun and Chance Oil and Gas Limited Meeting

Date: November 6, 2018

Location: Teleconference

Attendees:

Na-cho Nyak Dun:

[redacted] Lands and Resources Manager

Chance Oil and Gas Limited:

[redacted] President
[redacted] VP Government and Community Relations
[redacted] Regulatory, Environmental and Community Relations Coordinator

Hemmera:

[redacted] Senior Project Manager
[redacted] Community Engagement and Consultation Specialist

Purpose and Objectives

The purpose of this meeting was to discuss implementation of the Engagement and Communications Plan. As per the Plan, Chance and FNNND were to meet and discuss implementation within three months of August 8, 2018, the date on which the Plan was completed. Chance hopes to outline a schedule for implementation of the plan.

To advance engagement, Chance discussed their potential exploration activity in Permits 14, 19 and 20. Chance intends to do limited amounts of exploration activity in these permits and recognizes there is a partial overlap with Vuntut Gwitchin Traditional Territory. In addition, Chance wanted to begin discussions on capacity funding and how this will be provided.

Meeting Discussion:

[redacted] began the meeting with introductions and a review of the meeting agenda. [redacted] remarked that the Confidentiality Agreement was being reviewed internally. [redacted] did not have any introductory comments. [redacted] said, as an introductory statement, that he is thankful [redacted] was able to join the call and that Chance looks forward to this relationship and moving forward with a project once it gets

defined. Chance is moving forward with engaging all the First Nations and implementing the Communications and Engagement Plans. Chance has a meeting with Gwich'in Tribal Council and Tetlit Gwich'in Council next week to discuss the implementation of the Plans. Chance has a small delay with Vuntut Gwich'in due to their election of a new Chief and Council. [redacted] asked [redacted] if there is an upcoming election in Mayo? [redacted] responded that there will be an election in March 2019 and she anticipates that it will be called in January 2019.

[redacted] explained that since meeting last with FNNND, Chance has relinquished Exploration Permit 0005 because this permit was close to a Vuntut Gwitchin habitat protection area. Therefore, Chance's acreage has shrunk by approximately 30,000 hectares. This difference is featured on the latest map that Chance will send to FNNND.

Moving on to the next agenda item, [redacted] began to explain Chance's outlook for activity in the next year. [redacted] explained how chance wants to work collaboratively with First Nations regarding the project size and scope. Some of Chance's acreage will expire on August 2019 (Permits 0006 – 0011 and 0019), and some permits have been extended for five years (Permits 0012-0017). [redacted] said that Chance is hopefully meeting with Yukon Government at the end of next week to address a settlement to Chance's lawsuit.

[redacted] explained that Chance's work for next year will involve many conversations with First Nations about what a potential project will look like. Chance will have to create a project definition, and an application for YESAB. Chance will need First Nations' support and to meet YESAB's requirements. In terms of the YESAB application, Chance would prefer to apply with a larger project and do a regional assessment. It is hard for Chance to know where the wells will be before they complete more exploration because the location of new wells will be determined by the results of drilling. They may find something that redirects their efforts. Chance requires more fulsome conversations to adapt the project to meet First Nations' needs and to establish economic benefits.

[redacted] further explained how the scale of Chance's activity is intended to be small. Chance will move from one location to the next and spend one month at each well. The work will start-off as seasonal as they are restricted to winter operation initially. Winter operations will continue until they find a significant discovery that they will then want to test for two-years. The two-year testing period would require all-season access for maintenance and safety reasons.

For now, [redacted] said that Chance is anticipating operating on the west side of the Dempster, and potentially on the east side once they are further into exploration. They may want more seismic, but they have not decided where yet. [redacted] said he would forward a summary of the exploration project to D. Hope. This summary explains the rationale for a regional assessment, a few reasons being that Chance would like to provide time for learning curves for new employment opportunities and it is expensive to start and stop activities.

[redacted] explained that Chance is planning an in-person all-party meeting. [redacted] also wondered how the FNNND election would affect that meeting, and the process of working with Chance on implementing the Plans and creating a project description. [redacted] responded that FNNND is working on some internal organization to enable processes to move smoother in the future as they are tightening up implementation and operations internally. She does not think that the election will hold up too much with

[redacted] asked if Victoria Gold took a large portion of FNNND's capacity. [redacted] responded that that project had a separate staff. [redacted] also added that an all-party meeting was a good way to go because everyone would come away with the same understanding, and information can be provided all at once.

[redacted] asked about timing for FNNND's review of the Confidentiality Agreement. [redacted] said she would follow-up internally and get back to Chance and Hemmera.

Everyone on the call shared some information regarding general availability for an all-party meeting. No conclusive date was set.

[redacted]

to the potential project. [redacted] said that FNNND would discuss capacity funding internally. [redacted]

[redacted]

[redacted] raised that she would be including additional FNNND colleagues. They are [redacted] and [redacted], both Executive Directors. [redacted] would confirm how involved these employees would be in upcoming meetings with Chance, or if they would just be involved internally.

The next meeting was scheduled for November 26th at 1:30pm as a teleconference and this concluded the meeting.

Action Items/Next Steps:

Action Item	Responsible Party	Date Required
Review Confidentiality Agreement	FNNND	November 26, 2018
Conduct internal discussion on capacity funding needs	FNNND	November 26, 2018
Send Exploration Project Description	Chance	Sent on November 7, 2018
Send Chance's latest Exploration Permit Map	Chance	Sent on November 7, 2018

Key Meeting Outcomes

Outcome	Responsible Party	Notes
Initial implementation of the Communications and Engagement Plan	All	

Outcome	Responsible Party	Notes
Sharing of Chance's project plans for the next year	Chance	
Support established for an All-Party Meeting	All	

DRAFT

APPENDIX 2-A-07. February 1, 2019, Meeting Summary

Summary

Chance Oil and Gas Limited All-Party Meeting

Date: February 1st, 2019 **Time:** 8:00 am to 4:15 pm

Location: Princess Louisa Room, Fairmont Waterfront Hotel, Vancouver, BC V6C 3L5

Meeting Participants:

Vuntut Gwitchin Government:

- Chief [redacted]
- [redacted] Fish and Wildlife Manager
- [redacted] Lands Manager
- [redacted] Intergovernmental Coordinator

First Nation of Na-cho Nyak Dun:

- [redacted] Deputy Chief
- [redacted] Lands and Resources Manager
- [redacted] Strategic Advisor

Gwich'in Partners (Gwich'in Tribal Council and Tetlit Gwich'in Council):

- Chief [redacted]
- [redacted] Director, Lands and Resources

Yukon Government

- Minister [redacted] Energy, Mines and Resources and Economic Development
- [redacted] Assistant Deputy Minister, Oil, Gas and Mineral Resources, Energy, Mines and Resources
- [redacted] Director, Oil, Gas and Mineral Resources, Energy, Mines and Resources

Chance Oil and Gas Limited:

- [redacted] Chairman/ CEO
- [redacted] President
- [redacted] Vice President of Community and Government Relations
- [redacted] Regulatory, Environmental and Community Relations Coordinator

Hemmera:

- [redacted] VP Human Environment
- [redacted] Business Leader, Human Environment
- [redacted] Human Environment Specialist
- [redacted] Human Environment Specialist

DRAFT

Summary:

Topic	Lead
Introduction to Meeting • Review of Agenda • Meeting purpose and objectives Summary: Hemmera was hired in 2017 to assist with the consultation and engagement activities for Chance's exploration project in Eagle Plains.	[redacted]
Round Table Introductions and Opening Statements by Chiefs Summary: Chief [redacted], Minister [redacted] Chief [redacted], and [redacted] provided opening statements.	All Parties
First Nation Engagement Plans • Overview of how we got here and an update on implementation Summary: Chance's current round of engagement was spurred by the 2016 OIC, followed by the 2017 Ministerial Order. A series of meetings started in 2018 to collaboratively create engagement plans, starting with a template, then building out from there. This resulted in unique documents between Chance and each First Nation. Annual reports are required under the 2018 Ministerial Order. Likely not an onerous task, and along the lines of a communication summary. Level of detail will likely be decided by individual First Nations. ***See Appendix 1 – Chance All-Party Meeting: Engagement Plan Presentation***	[redacted]
Overview of Vuntut Gwitchin Government Oil and Gas Engagement Policy Summary: Vuntut Gwitchin Government (VGG) wanted an opportunity to share with the group the work VGG has done over the past year. Guiding principles of the VGG Oil and Gas Engagement Policy (Policy): sustainable development; the NYRLUP; VGG Final Agreement; past learning experiences with YESAB (e.g., gaps in regulatory regime in the Yukon); international standards. The development of oil and gas is a community decision. The Policy is two pieces/themes: internal engagement within the community and how the community will decide on oil and gas; and, external engagement with industry (i.e., the Policy establishes a committee). The Policy itself has three phases. All phases are meant to occur prior to a YESAB submission. VGG believes the new YESAB process (i.e., Pre-Submission Engagement process) largely aligns with the objectives of the Policy. Currently, we are before stage one – waiting for notification from Chance Question: Regarding the format/structure diagram – in terms of YESAB, once an application is complete and there is feedback, does that go to the Council? VGG: Feedback goes back into the whole loop – the loop including Council, the committee, and citizens. The committee isn't an interface between the VGG and YG. The committee would be tasked, as per its specific role, and then they would	[redacted]

DRAFT

report back to the Chief and Council after having done their work. At a later date VGG could expand on the internal processes for clarity.

See Appendix 2 – Chance All-Party Meeting: VGG Oil and Gas Engagement Policy Presentation

Exploration Project Description and Discussion

- Overview of the exploration project plans, oil and gas disposition plans, and YESAB application
- Answer questions or provide clarity on the Exploration Project Description

[redacted]

Summary: First exploration of oil and gas occurred in the Yukon when it was still being permitted by Ottawa back in the 50s, 60s, 70s. Red polygons on the permit map – legacy of exploration done approximately 1959-1968 when oil was found in the Yukon. These properties by themselves are not adequate to move forward with development – more needs to be discovered.

Question: For the discoveries, are conventional or non-conventional means required?

Chance: Do not need to stimulate the rock to facilitate production. Conventional means of extraction would be used.

Winter 2013/2014 had 3D seismic activity, the first in the Yukon. Chance has a base camp that can house 75 people. A limiting factor is man power (i.e., limited places to stay). Land tenure is the period of time that a permit is valid. On the Permits Map, the colour pertains to how the tenures have been extended.

Exploration activities can entail a number of things. Seismic: now lines carved through the bush are not straight, there is no line of sight, and the line are much narrower than those in the 1950s and 1960s. 3D seismic allows you to collect subsurface information in all directions. Exploration activities will include running a basecamp. Chance has to bring up everything needed in order to undertake an activity. Exploration is the riskiest part of the oil and gas industry, and the hardest part of the industry to get money allocated. A population of wells, in order to drill, learn more, and increase your probability of success is preferred.

Question: If Chance went with a 35 well program – is it 35 well pads on the surface with horizonal drilling under ground, or 35 wells total?

Chance: Not certain if we've thought well enough ahead to know that. Not all 30 wells will be exploratory. If something is found, then may need to drill in the vicinity. Possibly drill from the same well pad or one close to it in order to get a better idea of the resource.

YTG: Each well would be authorized. Not by pad.

Question: Would activities be primarily seismic first?

Chance: We do not necessarily have to shoot seismic in order to drill right now as there is legacy data. Chance does not have to do new seismic in all cases.

Chance's goal is to discover and develop a resource that meets the needs of the North and then expand. Chance wants to build local capacity. Around 80% of what Chance needs to

DRAFT

execute a program they cannot get from the Yukon (i.e., a supply line from the Edmonton area is required). If the supply chain can be shortened, it is building capacity and economy in the Yukon. Additionally, it is cheaper to operate in a continuous fashion as opposed to stopping and starting (more costly).

Question: Would activity be year-round?

Chance: Depends on the production, depends on the nature of the access. All weather access is the Dempster. However, if discoveries are made elsewhere, may need to consider all weather access off the Dempster.

Chance would assess before going out on the land to minimize footprint (e.g., build winter access on existing access routes is preferable)

Chance's drilling plan would have one rig maybe two at any given point. Trying to have a smaller scale over a longer period of time. This gives people/community time to get ready, buy equipment, get training.

Question: The concept around winter road versus summer road. All season road would be required if you need to flow test, correct? A year-round fixture on the land?

Chance: Yes, if you are flow testing then you are taking a product out of the ground, over longer periods of time, and you need to get equipment to test it (e.g., trucking operations in the testing period).

Question: For the purpose of the proposal, would that be addressed?

Chance: Yes, it would be covered off in the proposal.

First Chance would go with winter access. and then explain what would happen in the future with a well (e.g., if a well bears fruit, then this is where permanent access would need to be). This would be in the proposal to YESAB.

A multi-well program in an identified area of interest would ensure flexibility. If something is discovered, there will be a significant green house gas reduction (i.e., supply line will be reduced). The camp location was the location used when the highway was under construction – Chance is trying to reactivate/reuse previously disturbed areas.

Question: What does 300 million litres mean?

Chance: The amount of fuel trucked around the Yukon. Fuel is carried in two truck trailers that carry 50,000L each. Chance is likely not going to take out the full 300 million litres but could reduce it to 200 million litres. 2000-3000 barrels a day would remove the need to get fuel to the Yukon. The source would be local instead of foreign. 2000 barrels is about 11 truck loads.

Question: VGG has about 20 monitoring stations to keep a close eye on what's going on in the watershed – how can Chance participate in that?

DRAFT

Chance: Will need clarification, but Chance will be identifying data gaps. E.g., creeks in the area of interest. There is going to be monitoring place for parties to track what's going on. With respect to the Policy. There are stages to go through, and they align well with YESAB processes. Fairly soon Chance is going to have to work on/refine its project scope. Chance's objective is to build capacity and try to operate as continuously as possible. Sequencing of project activities would need to meet Chance's capacity. In the start limited to winter activities. Steady work gives the basis for local businesses to commit to local training. YESAB takes quite a bit of time, and the tenure clock is always ticking. There is a cost associated with multiple entries into YESAB. Question: 400 km/sq area? What area? Chance: Area of interest is about 40% of the total area under permits (See Appendix 3) Question: Expectation of timing for field work and the YESAB process? Chance: Ideally, field work two years from now, after YESAB. Also, likely an application to the Yukon Water Board. Confirming scale and scope with the hope to enter YESAB later this year. Have to satisfy the Policy and any new changes to YESAB. VGG: Can see the benefits but weigh it with concerns for the land and waters. Parties have different mandates but there is overlap. Cooperation Agreement and the front-end approach could be beneficial. Time pressure yes, but it will facilitate YESAB and YOGA agreement. A balance to be struck with timelines and capacity. There is limited oil and gas experience in the Yukon, and the Yukon is nothing like the rest of the country because there is robust land use planning and the power of the people. Mandates come from the people and this will benefit the people. Both sides have significant investments. Acknowledges that parties have and are seeking different requirements: certainty versus flexibility. Question: Is the NYRLUP up for review? It was completed in 2009, parties to the plan have been talking about what a review looks like. Currently assessing the plan to see where it's doing its job and where it might not be (Note: the plan will have new lines/boundaries). Minister Ranj Pillai departed 11:26 am. ***See Appendix 4 – Chance All-Party Meeting: Chance Oil and Gas Project Description Presentation***

DRAFT

Presentations and Discussion • Yukon Environmental Assessment Process • Other regulatory processes such as YOGA and the Water Act Summary: YESAA, YOGA, and the Water Act each have various regulations that could apply to any number of activities. There are other departments involved as well (e.g., workers compensation). No work or activity can occur before a decision document and a water license has been issued. Question: What will be the decision body be for Chance's project? YG: Likely Oil and Gas Branch if YESAB process is District Office (DO), or Major Projects Office if it is an Executive Committee (EC). There are three types of processes. DO, EC (typically a longer process and handled out of the head office in Whitehorse, has timelines, specific requirements for consultation prior to submitting an application to YESAB), and panel process. January 2019 YESAB released information around a new process. Pre-Submission Engagement process (PSE). Currently, proponents are creating the entirety of the project proposal and submitting it all at once. Proponents have not had a facilitated process with YESAB prior to submission (i.e., opportunity to receive feedback on scope and size) and this has downsides. It's possible to have 5-10 years of exploration and baseline data. Then have YESAB require baseline data on a separate matter. Providing guidance and direction around scope and valued components would be beneficial to the process and ensure that a proposal is moving in the right direction during development. There are information sessions in the coming weeks, and the process may come into force fall 2019. It is possible that this could reduce time spent on information requests. The intention being to take time away for the stages/process after submission. Question: How will this mirror or link into VGG Oil and Gas Policy? VGG: VGG is also new to what is being proposed by YESAB. After looking at preliminary materials, it appears to align well with the Policy. Question: If Chance proceeds through the three stages of VGG, is the new YESAB process a requirement? Hemmera: Not a requirement yet, but it will be. If a proposal is submitted to YESAB before the new process is in effect, it would proceed under the old/current process. The new PSE process is consistent with what the Federal Government has done and also what BC has done with their new Environmental Assessment process. Question: If Chance proceeded prior to the implementation of the PSE and followed the Policy, would Chance be doing the same activity? Hemmera: The Policy is only for VGG. The PSE process is for everyone, including VGG. Additionally, YESAB collects the views of all of the Yukon. Question: Should Chance implement the PSE process before it is mandatory?	[redacted] All Parties

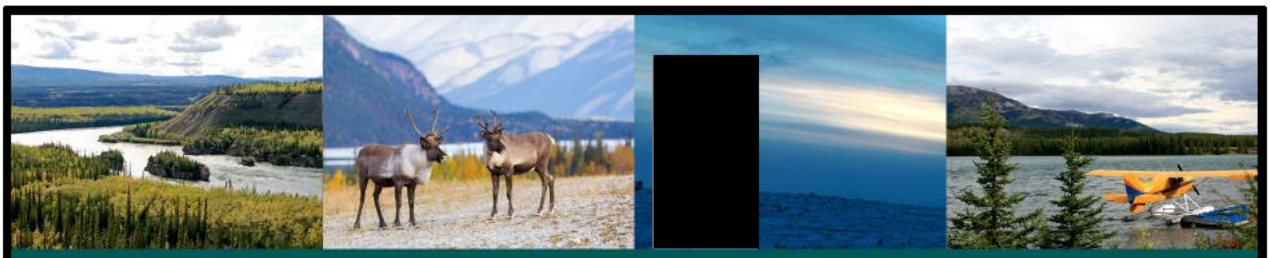
DRAFT

Hemmera: That is for the group to weigh the pros and cons and decide. Nov 2019 is an estimated date and a Federal election may cause more delays. Question: Is this legislation? Is parliamentary time required? Is this a policy, regulatory, or legislative change? Hemmera: This is a question for YESAB. YESAB is independent of the government and they are changing their rules. Maybe gazetting? Because YESAA is a Federal act. YESAA will set out the rules for processes and what consultation is necessary. ***See Appendix 5 – Chance All-Party Meeting: Regulatory Processes Presentation***	
YESAB Application Process • Where are we? • Anticipated timelines and mapping next steps Suggestion (Chance): Moving forward there will need some form of information exchange. Depending on the information, may need to be exchanged in a confidential manner. Finish Confidentiality Agreements. Chance has shared project ideas. Chance is open to feedback. Look into which steps can be done concurrently. Budget estimates and items associated with capacity will assist Chance with internal approval processes. Suggestion (Chance): Future discussion on whether or not there could be agreement or interest in using common consultants – where needed for professional and technical advice. Trying to get common recommendations. Feedback: This may be a good idea on the technical front and a capacity one. However, a biological or cultural assessment, First Nations may want to do that independently. Question: Is YG interested in doing oil and gas 101? YG: YG is amenable to doing oil and gas 101s. Different presentations could be tailored for different audiences Suggestion (VGG): Use previous documents (multi-well project) and analyze the criticism against them, to work on the areas within them, and bring them to a place where the parties support them. E.g., are concerns some that were raised by multiple people, or ones born of miscommunication? Feedback: Hemmera will be conducting a gap analysis to evaluate what is needed to apply to YESAB again (i.e., looking at everything from the DO screening and, if there is an EC, what more is needed). Take those comments from the registry (from the DO process) and evaluate whether there were adequate responses or if since then, different information has arisen, or more adequate best practices have been developed. Suggestion (VGG): Put our minds to the monitoring plan and whether mitigation measures are doing what they should (i.e., applying adaptive management). **Next steps as they were listed on the flipchart** • **Confidentiality Agreements**	[redacted] All Parties

DRAFT

• **Project Scope** • **Processes in Parallel vs. Sequentially** • **Shared consultants – technical disciplines** • **Oil and Gas 101** • **Adaptive Management**	
Wrap Up and Closing Statements Question: Is it useful to have All-Party meetings? Summary: Parties agreed it was valuable. Future All-Party meetings could be timed with key milestones and planned to proceed/follow other key dates/events. VGG: Offered to send a list of key dates/events that could be used. Summary: Chief [redacted], Chief [redacted], and Yukon Government provided closing statements.	S. Shaw

DRAFT



The Engagement Plans:
Development and Next Steps

Hemmera
An Ausenco Company

Creating the Engagement Plans

- Chance's current engagement with First Nations was prompted by M.O. 2017/37
- M.O. 2017/37 requested that Chance file Engagement Plans with each of the affected First Nations listed in the M.O.
- All Engagement Plans were filed in summer 2018

O.I.C. 2016/169
OIL AND GAS ACT

OIL AND GAS ACT

Pursuant to section 10 of the *Oil and Gas Act* and subsection 12(6) of the *Oil and Gas Disposition Regulations*, the Commissioner in Executive Council orders

1 In this Order

"subject permit" means each of the following oil and gas permits held by the subject permittee

(a) oil and gas permit No. 0005,

(b) oil and gas permit No. 0006,

M.O. 2017/37
OIL AND GAS ACT

OIL AND GAS ACT

Pursuant to section 31.01 of the *Oil and Gas Act*, the Minister of Energy, Mines and Resources orders

1 In this Order

"affected First Nation" means each of the Vuntut Gwitchin First Nation, Tr'ondëk Hwëch'in First Nation, First Nation of Na-Cho Nyak Dun, Gwich'in Tribal Council and Tetlit Gwich'in Council; « *Première nation concernée* »

"subject permit" means each of the following oil and

Next Steps

- M.O. 2018/ 42 orders that Chance submit annual reports on the First Nations Engagement Plans (due on July 31 of each year)
- Continue with Plan implementation
- Continue engagement with each First Nation individually, and also as a group

YUKON

CANADA

MINISTERIAL ORDER 2018/ 42

OIL AND GAS ACT

Pursuant to the *Oil and Gas Act*, the Minister of Energy, Mines and Resources orders

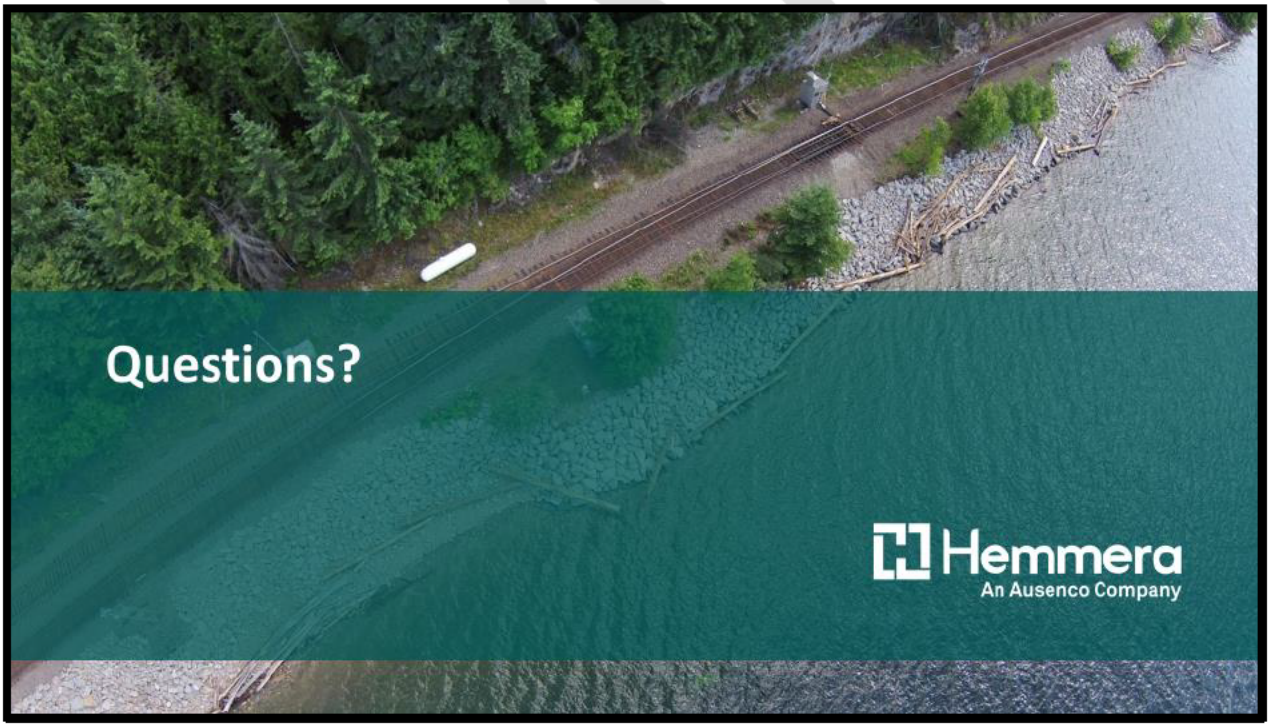
1 In this Order

"subject permit" means each of the following oil and gas permits held by Chance Oil and Gas Limited:

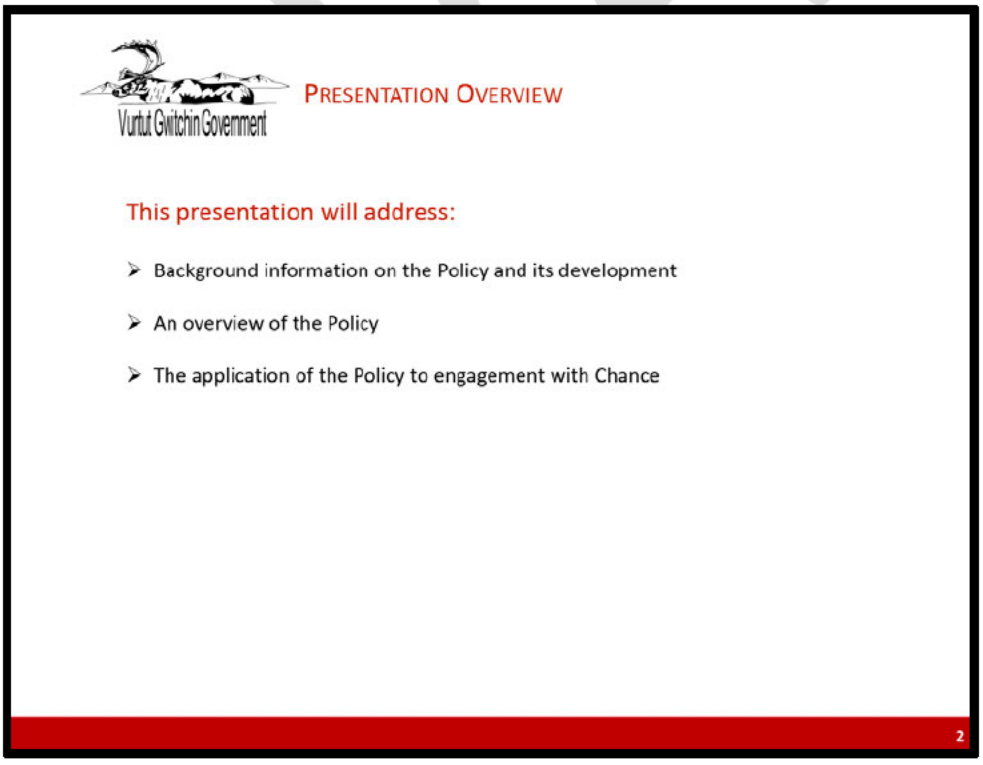
(a) oil and gas permit No. 0012,

(b) oil and gas permit No. 0013,

(c) oil and gas permit No. 0014,



VUNTUT GWITCHIN GOVERNMENT
OIL AND GAS ENGAGEMENT POLICY:
BACKGROUND AND OVERVIEW
Vuntut Gwitchin Government
This presentation was prepared by the Vuntut Gwitchin Government for discussions with Chance Oil and Gas on December 12, 2018 in the traditional territories of the Kwanlin Dün and Ta'an Kwäch'än



Vuntut Gwitchin Government
PRESENTATION OVERVIEW
This presentation will address:
Background information on the Policy and its development
An overview of the Policy
The application of the Policy to engagement with Chance
2

Vuntut Gwitchin Government

BACKGROUND

The development of the Policy was informed by:

- The principle of sustainable development as enshrined in the VGFN Final Agreement and North Yukon Regional Land Use Plan
  - "'Sustainable Development' means beneficial socio-economic change that does not undermine the ecological and social systems upon which communities and societies are dependent" [VGFN Final Agreement, Chapter 1].
  - "The core principle that guides the Plan is sustainable development, as defined in the VGFNFA... Sustainable development requires consideration of the economic, social and ecological consequences of land use decisions, and management of lands and resources in an integrated and coordinated manner" [NYRLUP]
- The principles, goals, recommendation and best management practices provided for in the North Yukon Regional Land Use Plan

3

Vuntut Gwitchin Government

BACKGROUND

The development of the Policy was informed by:

- Past experience of engagement activities with proponents and in participating in the YESAB assessment process
  - "The Designated Office is unable to determine if adverse effects to the access to and use of the PCH are or are not significant... development in the region is not intrinsically adverse, but rather that additional information is required to make confident effects predictions and to determine the significance of those adverse effects. The requirement for confidence in predicting effects in this assessment is elevated for two reasons: first, the significant importance for the First Nation and the Inuvialuit way of life that is intrinsically linked to the PCH; and second, the unprecedented scale of the Project within this region" [YESAB DO Report].

4

BACKGROUND

The development of the Policy was informed by:

- Shortcomings in the existing territorial regulatory regime
  - "VGG would like to address our concerns with provisions of the Yukon Oil and Gas Act, R.S.Y. 2002, c. 216 and its associated regulations as it relates to benefits agreements and permit extensions. Additionally, VGG would like to resume the development of resource access roads regulations under the Territorial Lands (Yukon) Act, S.Y. 2003, c. 17" [VGG Letter to Premier Silver, May 10, 2017].
  - "The most recent annual report for the NYRLUP stresses the need for baseline data collection and development of best management practices in order to better understand and predict effects. Industrial development in the region is predicated upon fulfillment of goals for information collection as set out in the NYRLUP and associated annual reports" [YESAB DO Report].

5

BACKGROUND

The development of the Policy was informed by:

- An identified need for public policy that establishes a framework for respectful, meaningful and transparent engagement
  - "It is a condition of this Order that Chance Oil and Gas Limited must, in consultation with each affected First Nation, revise the first nations communications and engagement plan filed under O.I.C. 2016/169 to the satisfaction of the Minister on or before August 1, 2018" [Ministerial Order 2017/37].
  - "[THEREFORE BE IT RESOLVED] That VGG proceed with efforts that lead to constructive engagement with oil and gas industry proponents and government agencies including partnerships in the areas of employment and training, environmental stewardship and business development" [VGFN GA Resolution No. 2017-02].

6

Vuntut Gwitchin Government

BACKGROUND

The development of the Policy was informed by:

- International standards and best practices
  - "Indigenous peoples have the right to determine and develop priorities and strategies for the development or use of their lands or territories and other resources... [and to] free and informed consent prior to the approval of any project affecting their lands or territories and other resources, particularly in connection with the development, utilization or exploitation of mineral, water or other resources" [UNDRIP, Article 32].
  - "FPIC is relevant... in relation to development projects encompassing the full project cycle, including but not limited to assessment, planning, implementation, monitoring, evaluation and closure" [UN Permanent Forum on Indigenous Issues, Report of the International Workshop on Methodologies regarding Free, Prior and Informed Consent and Indigenous Peoples].

7

Vuntut Gwitchin Government

BACKGROUND

The development of the Policy was informed by:

- International standards and best practices
  - "Due to the fragility of arctic environments, with high vulnerability to climate change, the high proportions of Indigenous peoples within arctic populations, and increasing resource development pressures, Indigenous-led impact assessment is particularly important... [Indigenous-led impact assessment] is a process that is completed prior to any approvals or consent being provided for a proposed project, which is designed and conducted with meaningful input and an adequate degree of control by Indigenous parties—on their own terms and with their approval. The Indigenous parties are involved in the scoping, data collection, assessment, management planning, and decision-making about a project" [Gwich'in Council International, Impact Assessment in the Arctic: Emerging Practices of Indigenous-Led Review].

8

Overview of the Policy

The main components of the Policy include:

- A clearly defined purpose section
  - "The purpose of this policy is to establish a respectful, transparent and meaningful framework to guide the engagements of the Vuntut Gwitchin Government in relation to Oil and Gas Activities and Oil and Gas Dispositions in a manner that supports and upholds the objective of Sustainable Development" [section 3].
- The establishment and mandating of a committee to facilitate the participation of Citizens in the engagement and decision-making process
  - Membership consists of Standing Committee Chair on Natural Resources, Director of Natural Resources, Elders Representative, Youth Representative and Citizen Representative [section 12].
  - Mandate includes informing and seeking views from Citizens, and assisting and providing recommendations to the Council throughout the Engagement Process [section 11].

9

Overview of the Policy

The main components of the Policy include:

- A process to guide the organizing and carrying out consultations with Citizens regarding Oil and Gas Activities and Oil and Gas Dispositions
  - Director of Natural Resources has primary responsibility for organizing and carrying out any consultation between the Vuntut Gwitchin Government and Citizens regarding Oil and Gas Activities and Oil and Gas Dispositions with the assistance of the Committee as necessary [section 20].
  - Proponents are to coordinate any of its consultation with Citizens by submitting written notice to the Director of Natural Resources that sets out proposed date, location, agenda, description of the purpose of the meeting and any materials to be shared with Citizens [section 21].

10

Overview of the Policy

The main components of the Policy include:

- A three stage process for engagement with Proponents in relation to any Oil and Gas Activity to be completed prior to the Proponent submitting any Proposal to the Board
- Stage 1: Notice Period
  - Sufficient notice of a proposed Oil and Gas Activity must be provided to the Director of Natural Resources at the earliest opportunity [section 24].
  - Director of Natural Resources will refer the notice it receives from the Proponent to the Committee who will review it for sufficiency. The Committee will notify the Proponent in writing of its determination. If notice is not sufficient then more information will be requested. If notice is sufficient then engagement on the Oil and Gas Activity can proceed to Stage 2 [section 25].

11

Overview of the Policy

The main components of the Policy include:

- Stage 2: Cooperation
  - A Cooperation Agreement must be negotiated and entered into following Stage 1 and before proceeding to Stage 3 [section 26].
  - Prior to entering into a Cooperation Agreement, Council must refer the Cooperation Agreement to the Committee. The Council can enter into the Cooperation Agreement if the Committee determines that the Cooperation Agreement adequately addresses items related to compliance with the policy, communications, information sharing and capacity funding [section 27].
  - If a Cooperation Agreement is entered into in relation to an Oil and Gas Activity then the engagement process proceeds to Stage 3. A Cooperation Agreement does not provide free, prior and informed consent to any Oil and Gas Activity.

12

Vuntut Gwitchin Government

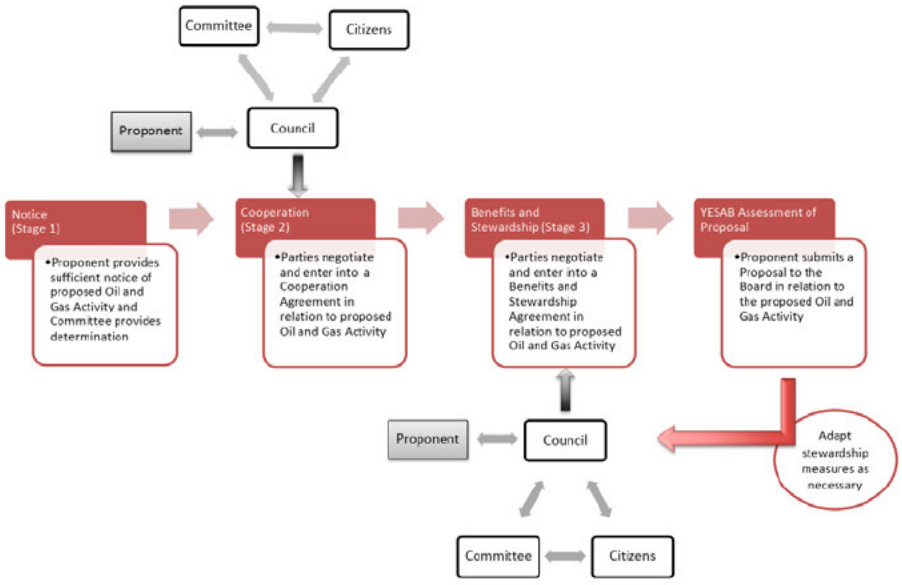
Overview of the Policy

The main components of the Policy include:

- Stage 3: Benefits and Stewardship

  - A Benefits and Stewardship Agreement must be negotiated and entered into following Stage 2 and before proceeding to the Board with a Proposal. It is the mechanism in which the free, prior and informed consent of the Vuntut Gwitchin First Nation is effectively to be provided in relation to any Oil and Gas Activity [section 28].
  - Prior to entering into a Benefits and Stewardship Agreement, Council must refer the Benefits and Stewardship Agreement to the Committee. The Council can enter into the Benefits and Stewardship Agreement if the Committee determines that the Benefits and Stewardship Agreement adequately addresses various items related to economic benefits and environmental stewardship [section 29].
  - Benefits and Stewardship Agreement will be subject to an approval and ratification process deemed adequate by the Committee.

13



14

Application of the Policy to Engagement with Chance

The Policy applies to engagement with Chance:

- Chance review of the draft Policy
- Chance acceptance of the final Policy
  - "Chance will comply with the Policy and any other applicable VGG policies. To the extent that there may be any inconsistency between this Plan and the Policy, the Policy will prevail" [Joint Communication and Engagement Plan]
  - "The Plan, which incorporates the Vuntut Gwitchin Government Oil and Gas Engagement Policy (the "Policy"), sets the framework for all communication and engagement between Chance Oil and Gas Limited ("Chance") and the Vuntut Gwitchin Government ("VGG") moving forward. Chance's commitment to the Plan and Policy is a significant achievement and provides an example for the outside world on how industry ought to approach oil and gas exploration and development in the North within a framework premised on free, prior and informed consent" [VGG June 11, 2018 Letter to Chance]

15

Application of the Policy to Engagement with Chance

The Policy applies to engagement with Chance:

- VGG and Chance engagement is currently in Stage 1 (Notice)
- Chance has shared scenarios for various Oil and Gas Activities at different scales but has not submitted notice of an Oil and Gas Activity it wishes to advance for further consideration under the Policy
- VGG has shared a draft Cooperation Agreement for discussion purposes prior to the completion of Stage 1 (Notice) and in advance of Stage 2 (Cooperation)
- Next steps: Chance to provide written notice of any proposed Oil and Gas Activity to the Director of Natural Resources at the earliest possible opportunity as provided under section 24 of the Policy

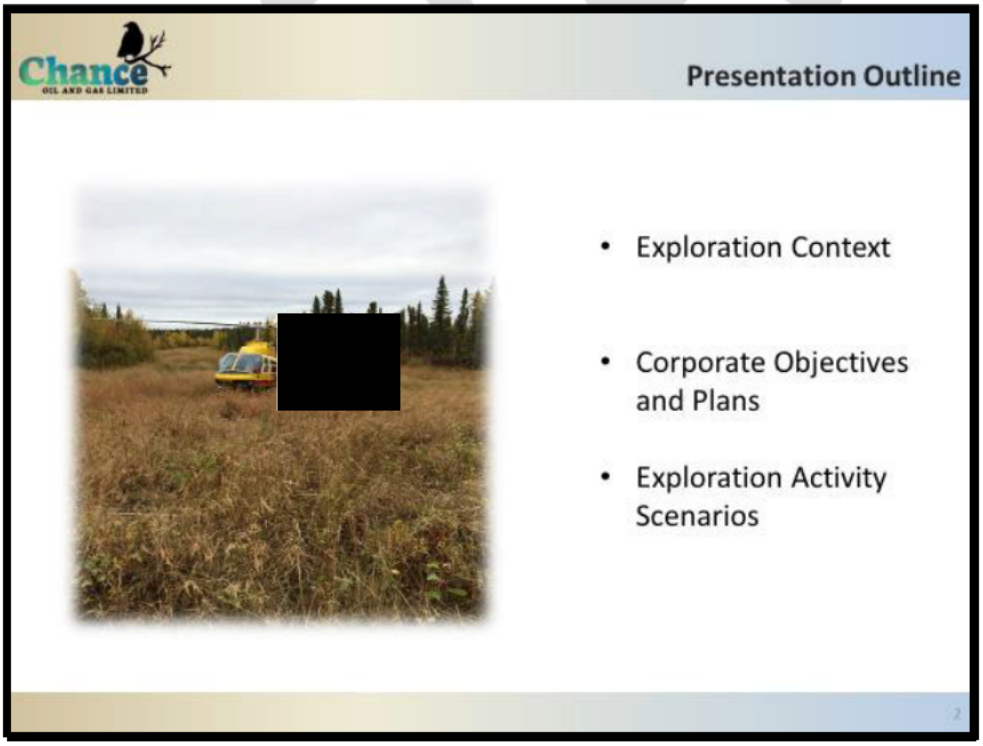
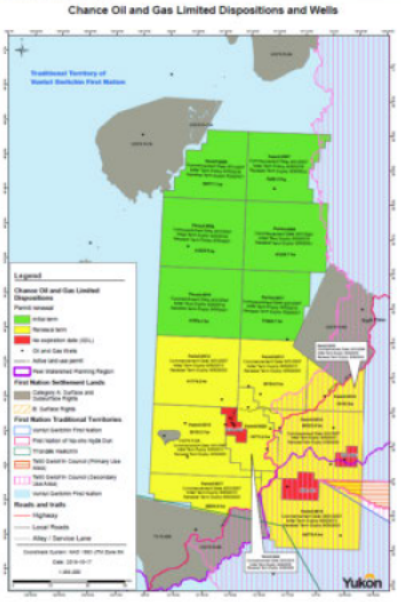
Chance Oil and Gas Limited
February 1st, 2019



Chance
OIL AND GAS LIMITED
Presentation Outline
[redacted]
• Exploration Context
• Corporate Objectives and Plans
• Exploration Activity Scenarios

Land Holdings Eagle Plain, Yukon



- 14 Exploration Permits (0006-0017, 0019-0020 expiring between Aug 30, 2019 and Aug 30, 2023
- 3 Significant Discovery Licenses ("SDL's") with indefinite tenure with discovered oil and natural gas
- Landholdings total about 490,000 hectares
- North Yukon Regional Land Use Plan indicates that this area is suitable for multiuse, including oil and gas industry activities
- Chance surrendered ep. 0005 in 2018 to allow the creation of Ch'ihilii Chik - HPA

3

Infrastructure and Support

- Eagle Plains is an underexplored sedimentary basin
- Discovered resources located at the SDL's is not sufficient to proceed to development
- Oil and gas exploration began in the 1950's and both oil and natural gas have been discovered
- Almost 40 wells have been drilled at Eagle Plains
- Over 10,000 kms. of 2D and about 325 sq. kms. of 3D seismic data has been acquired

4

Land Tenure

- Tenure is the length of time that exploration permits or leases are valid
- Tenure has a large influence on obtaining financing, planning activities and doing the work
- For a remote area like Eagle Plains, longer tenure is better than shorter tenure
- How the legal action against Yukon gets resolved will have an impact on tenure

5

Exploration Activities

- Field work to investigate the geological opportunities
- Acquiring more seismic data (both 2D and 3D)
- Exploration drilling of new wells
- Production testing of any discoveries showing commercial potential
- Construction of seasonal and year-round access trails and roads
- Installing and operating processing facilities connected with production testing

6

Exploration Activities

- Operating the base camp
- Converting wells for injection of water produced with oil and natural gas
- Logistical support for the camp and exploration activities
- Environmental data gathering and monitoring of operations
- No plan to do hydraulic fracturing

Exploration Activities

- Exploration work is the most expensive and most uncertain activity which affects funding commitments
- Exploration activities are unpredictable because results guide the future steps
- Plans are subject to change as priorities change with new information
- Even though Chance has several prospects to evaluate, drilling may find something that could not be predicted before hand that changes the plans
- Flexibility is needed from Assessors, regulators and goods and service providers to accommodate the uncertainties and need to adapt the activity as the work progresses

Objectives and Plans

- Based on current geological understanding, the area of exploration focus includes parts or all of Exploration Permits 0012-0016 and 0019-0020 and the three SDL's
- Acquire more seismic data and drill more wells to evaluate the resource potential
- Discover sufficient oil and natural gas resources to support future development
- Develop discoveries to serve the regional market needs and possibly export markets if the resource base is large enough
- Undertake the exploration program on a small scale over a long period of time to minimize the environmental and social impacts
- Try to operate as continuously as possible to provide steady employment and minimize the high costs of starting up and shutting down

9

Benefits

- Develop local capacity to participate in the projects and displace high cost imported services and equipment
- Diversify the regional economy
- New business, training and employment opportunities
- Reduced GHG's by substituting imported fuel that is shipped thousands of kilometres with Yukon sourced fuel
- Potential to reduce the cost of fuel in the Yukon and surrounding area

10

Project Alternatives

- YESAB assessments are required in order to obtain regulatory approvals to undertake any exploration work
- Depending on the scale and scope of the program, the YESAB assessment could be done by the Designated Office in Dawson or by Executive Committee in Whitehorse
- Two project execution scenarios can be considered: 1) a series of short duration, limited activity projects each with its own YESAB assessment; or 2) one longer duration, but limited scale project over the entire exploration region that undergoes one comprehensive YESAB assessment
- All work is exploration to evaluate the resource potential in order to understand whether the opportunities can eventually be developed commercially

11

Activity Scenarios- Issues to Manage

- YESAB processes are expensive and lengthy
- Lengthy assessment processes grind the tenure clock
- The cost of multiple assessments could hurt the amount of exploration work
- Multiple YESAB assessments of shorter duration, limited scope exploration work means intermittent employment
- Financial and project management are more efficient under a regional YESAB assessment of exploration in a broader area, but still small-scale operation (e.g. a single drilling rig or a single seismic survey)

YESAA Assessment Process

- Assessors look at the potential environmental and socio-economic effects of proposed activities and recommend whether the activities should proceed, proceed with terms and conditions, or not proceed.
- When assessments are complete, recommendations are sent to the relevant Decision Body(s)
  - Designated Office Evaluation
  - Executive Committee Screening
  - Panel of the Board of Review
- Decision Body(s) decide to accept, reject, or vary YESAB's recommendation
- Decision Document issued

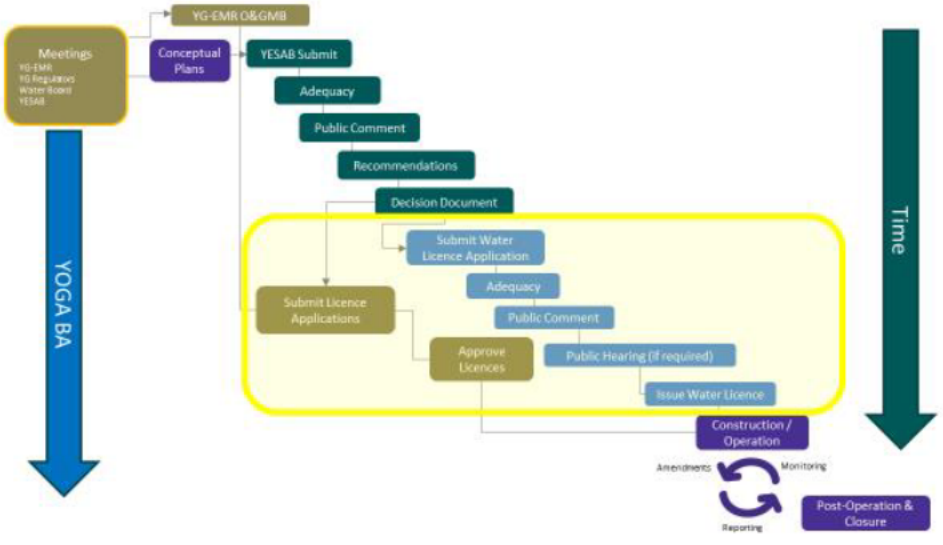
YESAA Assessment Process

New: Pre-Submission Engagement (PSE) process

- YESAB approved the PSE and it will come into effect late Fall 2019 (estimated).
- For Executive Committee screenings only.
- Brings parties together to review project requirements in advance of proposal submission.
- Helps identify gaps and issues of concern, define values and baseline information requirements, and ensure a timely and certain screening process.
- "Terms of Reference" style of process

Licensing Process



Yukon Water Use Licence [1/2]

- Use of water or deposit waste into water
- Petroleum exploration/development are "Industrial Undertakings"
- Interim - Oil and Gas Information Package for Applicants (2013)
- Quasi-judicial board supported by Yukon Water Board Secretariat

Yukon Water Use Licence [2/2]

Choice of Type A vs Type B will drive information requirements, process, and timelines

- Hearing required for Type A
- Both require YESAA decision document prior to issuance

Permitting and Licensing

1. Land Use Permit (YG – EMR, Land Management)
2. Well Licence and Well Operation Approval (YG – EMR, Oil and Gas Resources)
3. Permit for Air Emissions (YG – ENV)
4. Temporary Highway Access Permits (YG – HPW, Transportation Branch)
5. Water Licence/Notification of Water Use (YG, Water Board)
6. Dempster Highway Area Authority Authorization

YOGA Well Licence

- First Nation and community consultation prior to application
- Benefits Agreement for projects >$1M/year
- Requires YESAA decision document prior to issuance

APPENDIX 2-A-08. June 10, 2019, Meeting Summary

First Nation of Na-cho Nyak Dun and Chance Oil and Gas Limited Meeting

Date: June 10, 2019

Location: Na-cho Nyak Dun Government Building

Attendees:

First Nation of Na-cho Nyak Dun (FNNND):

[redacted] – Acting, Lands and Resources Manager
[redacted] – Land Use Planning
[redacted] – Victoria Gold Liaison
[redacted] – Lands Assistant
[redacted] – Strategic Advisor

Chance Oil and Gas Limited (Chance):

[redacted], President
[redacted], VP Government and Community Relations
[redacted], Regulatory, Environmental and Community Relations Coordinator
[redacted], Board member and Chair of Community Relations Committee

Hemmera:

[redacted], Human Environment Specialist
[redacted], Human Environment Specialist

Introduction: Purpose and Objectives

The purpose of this meeting was for Chance to present a Draft Project Description of exploration activities proposed for the Eagle Plain Basin. Parties also discussed next steps with YESAB and the process for reviewing Na-cho Nyak Dun Project effects as well as the annual reporting required on the implementation of the Engagement and Communication Plan.

Meeting Objectives:

- Presentation of Draft Project Description
- Discuss Draft Project Description in more detail and provide clarity on any items if needed
- Discuss annual reporting requirement

DRAFT

Meeting Discussion:

Due to recent staff turn over [redacted] asked Chance to start with a high-level briefing. To help bring those new to the file up to speed.

[redacted] focused on the history of oil and gas exploration in Eagle Plains. Historically the company was called Northern Cross, they looked into old wells already in the region from drilling activities of previous businesses. Up until 1999, mineral resources were managed by Ottawa, then shifted to Yukon Territory. From 2007-2010 exploration permits were issued to Chance. Chance conducted some seismic surveys and drilling and then the fracking moratorium was implemented. [redacted] clarified that the project description that he was introducing and discussing that day – does not involve hydraulic fracturing. Chance provided a brief overview of the All-Party meeting that took place February 1, 2019. Chance has retained Hemmera for support for engagement and consultation activities and to facilitate/manage the YESAB submission.

The Chance presentation began with a general project description. [redacted] described some of the characteristics of old seismic lines. In the past they were 10 metres wide and were straight. Now they are narrow at approximately 2-3 metres. [redacted] clarified that over the ten-year period of the project, it is actually a series of small projects rolling out. This is because each step is based on/informed by discoveries of the step before. Additionally, it is not possible to drill and run a seismic program at the same time. Chance endeavours to have the ability to set up in a wide area and work continuously to, among other things, better attract Yukon businesses and employment.

A FNNND attendee asked where the disposal site for drill cuttings would be and/or if it has been identified. [redacted] stated that is difficult to narrow that down without information on where all the drill sites will be. Chance will need seismic data (for refining locations) and once they know where the drilling will take place they can determine where the sump will be. There are specific properties to make the sump viable.

FNNND asked if the historical discoveries were natural gas or oil. [redacted] stated that drilling in the 1960's found both oil and gas. There are 3 significant discovery locations: Chance, Birch, and Blackie. The Chance site included both oil and gas, Birch was comprised of natural gas (ethane), and Blackie was also natural gas (methane). The area that Chance is focusing their project is approximately 2800km^2. [redacted] informed FNNND of bird surveys that are being conducted at the end of the month. As well as a field program Chance in carrying out to collect rock outcrop samples. [redacted] briefly highlighted [redacted]'s history in the Eagle Plains area.

[redacted] clarified that winter trails would be used for exploration, but that all-season roads would be required for flow testing.

FNNND inquired if Chance would be setting up a Porcupine Caribou working group. [redacted] mentioned that, in the past, a working group did not work well due to several reasons, one of which was poor attendance. Chance has hired Environmental Dynamics Inc. to study wildlife, in particular caribou, but still anticipates that they will be setting up a committee of some kind. Chance will also have a monitoring system that will have people in the field.

DRAFT

[redacted] explained that while there is water below ground where Chance will be drilling, it is not potable. It is very saline. Mud from drilling

FNNND asked what volume of water does Chance expect to use? [redacted] stated that the camp currently uses 15-20 cubic metres and water used for the drill actually circulates water.

[redacted] stated that the project presented by [redacted] will be submitted to YESAB for an Executive Committee level screening. In 2014, a project was submitted to YESAB as a District Office screening. At that time it was referred to Executive Committee. While there are similarities with the 2014 submission, the project presented by [redacted] is largely being treated as its own project. New consultants have been hired and the level of consultation will be far more intensive. Currently, Chance and FNNND are in the pre-submission consultation phase. In the future, both YESAB and YG will consult with the First Nations. [redacted] explained a proposed timeline for baseline studies and activities/requirements leading up to a YESAB submission end of January 2020. Hemmera is preparing role profiles to facilitate First Nation members to accompany some of the upcoming field surveys. [redacted] also informed FNNND that they intend to run a traditional knowledge study and current use study which will likely be paired with other studies (e.g., wildlife – porcupine caribou).

[redacted] explained that once the proposal is submitted to YESAB, then YESAB performs its own consultation with First Nations and Yukoners. First Nations will be asked if they were satisfied with the consultation done by the proponent. Moving forward, Chance will have a series of meetings in the communities and sometimes those meetings will focus on a specific subject matter (e.g., permafrost, birds, fish). Chance will be meeting with PCMB. [redacted] explained that PCMB meets four times a year, back and forth between communities in NWT and YT.

[redacted] stated that the multiple stages/phases of consultation moving forward through the YESAB process will require lots of effort and time for the First Nation. Usually FNNND has struck an IBA with the proponent, and usually there is no activity on the part of FNNND until an agreement has been arranged. Political discussions may be ahead. Maybe have all the northern leaders (VG, TH, FNNND), makes sense to be a coordinated approach amongst the First Nations and perhaps the creation of a technical group. [redacted] is hoping for the First Nations affected by this project to consider the idea of a singular consultant. [redacted] stated that development has to be sustainable and there has to be benefits. This project is a priority for Chance not FNNND. It is up to the proponent to deal with complications and pay the costs. [redacted] assumed that Chance will open this up to the community, first the First Nation and then the community at large. For FNNND moving forward, capacity support will be key. Is Chance prepared to enter into a formal agreement with FNNND – perhaps not an IBA but an exploration and cooperation agreement.

[redacted] asked if Chance wants to have one person within FNNND as their contact. [redacted] explained that the Engagement and Communication Plan between Chance and FNNND actually asks for contacts to be identified. In the past, Chance's main contact with FNNND had been [redacted]. [redacted] asked for the Engagement and Communication Plan to be sent to her.

[redacted] spoke to an upcoming deadline for a report/summary of the implementation of the Engagement and Communication Plan. The extension of a number of Chance's permits are tied to these reports. Hemmera's suggested approach is to keep this summary/report at a very high level. It will largely be drafted by Hemmera with Chance and FNNND to edit, refine, and finalize collaboratively.

DRAFT

Hemmera will use it's engagement log to shape the content and the hope is that YG is not expecting a lot of detail.

[redacted] mentioned that YG is organizing Oil & Gas 101s. FNNND was aware of this and had informed YG that the fall would be best. FNNND informed Chance that they meet once a month with YG.

[redacted] stated that he believed it was too early for a community meeting. [redacted] stated that the next step would be to meet with Chief and Council and the information provided in this presentation would shape the briefing note for Chief and Council.

Chance was asked if they would be meeting with the Mayo Renewable Resource Council, and they confirmed that that would be a component of their public engagement.

Action Items/Next Steps:

Action Item	Responsible Party	Date Required
FNNND Lands staff to brief FNNND Chief and Council.	FNNND	As soon as practical.
Send original Engagement and Communication Plan, All-Party Summary, YESAB 2014 DO Evaluation Report, and additional background documents to [redacted]	Hemmera	Sent by [redacted] June 11, 2019.
Hemmera will prepare a draft report for Engagement and Communication Plan. Chance and FNNND will review and refine collaboratively.	Hemmera	Will send draft to FNNND and Chance early July

Key Meeting Outcomes

Outcome	Responsible Party	Notes
Present Draft Project Description – discuss in more detail and provide clarity on any items if needed	Chance	
Discuss next steps in YESAB process	Hemmera	
Discuss annual reporting requirement for Engagement and Communication Plan	Hemmera	Hemmera will prepare a draft report. Chance and FNNND will review and refine collaboratively.
Discuss longer-term capacity funding	All Parties	This will be a key agenda item for the next meeting between Chance and FNNND.

DRAFT

APPENDIX 2-A-09. DFO License Application Notice Letter

Chance Oil and Gas Limited
Suite 1000, 340 – 12th Avenue SW
Calgary, AB T2R 1L5
T: 587.390.4136

June 14, 2019

Na-cho Nyak Dun
101 Future Rd. Box 220
Mayo, Yukon Y0B 1M0

Attention: [redacted] **Acting Lands and Resources Manager**

Dear [redacted]

Re: DFO License Application Notice

The purpose of this letter is to provide notice to the First Nation of Na-cho Nyak Dun (FNNND) of the intention of Environmental Dynamics Inc. (EDI) to submit an Application for a *License to Fish for Scientific, Experimental, Education, or Public Display Purposes, Under Section 52 of the Fishery (General) Regulations.* Chance Oil and Gas Limited (Chance) has contracted EDI to perform fish studies, among other environmental studies, within the project area described in the Draft Project Description delivered to FNNND on June 10, 2019.

The fish studies are scheduled to take place from July 1, 2019 to July 10, 2019 pending approval of the DFO license. Please see attached for EDI's application and list of watersheds and species for the permit.

If any questions should arise regarding the license application or EDI's field work, please contact [redacted] at Hemmera and she will coordinate a reply.

Sincerely,

[redacted]

Vice President Government and Community Relations
867.456.7805

Fisheries and Oceans Canada | Pêches et Océans Canada

APPLICATION FOR A LICENCE TO FISH FOR SCIENTIFIC, EXPERIMENTAL, EDUCATIONAL or PUBLIC DISPLAY PURPOSES, UNDER SECTION 52 OF THE FISHERY (GENERAL) REGULATIONS *(Yukon/Transboundary Rivers Area)*

(Check one, and provide the additional info if required)

☒ New Application

☐ Renewal of previous year's licence — Previous Licence #:

☐ Amendment to a current licence — Current Licence #:

(Check one)

☐ SCIENTIFIC PURPOSES *

☐ EXPERIMENTAL PURPOSES**

☐ EDUCATIONAL PURPOSES***

☐ PUBLIC DISPLAY PURPOSES****

(see footnote for descriptions)

Yes ☐ No ☒ **Do you have an Animal-Use protocol approved by a CCAC-accredited animal care committee?** *(http://www.ccac.ca/en_/standards/guidelines)*

1. Please briefly describe the purpose of your application request. If this is an amendment to a previous license, briefly describe the requested changes to the original license.

The Chance Oil and Gas Project Area covers approximately 2,500 km^2 and includes 1,467 streams. Very little fisheries data exists for the proposed Project Area, with the most recent (limited) sampling occurring in 2001. EDI Environmental Dynamics Inc. proposes to conduct fish sampling on streams from each order throughout the Project Area. Fish sampling will mostly be conducted using electrofishing methods, with beach seining where necessary on 4th or 5th order streams. Electrofishing effort will be approximately 100-300 meters and for a minimum of 400 seconds in order to adequately sample each site. The length of stream sampled will be proportional to the stream width (i.e., narrow creeks will be sampled for longer distance than wide creeks). Sites will be sampled a minimum of 100 m upstream from the nearest confluence. The planned target of sites is 50, with an allowance up to 100.

2. Indicate the desired start and end date for the requested licence/permit. (Licence/permits may only be issued for up to one year.)

Start Date: 2019-07-01 End Date: 2019-10-01

Details (Specify sampling periods, if applicable): *Sampling is intended to begin in mid-July, but may require subsequent sampling.*

3. Applicant Information:

Legal Name of Applicant: [redacted] Date of Birth: 1990-07-24

Organization or School: EDI Environmental Dynamics Inc.

Street Address/Unit#: 2195 Second Avenue City: Whitehorse

Province/Territory: Yukon Postal Code: Y1A 3T8

Phone: [redacted] Fax: Email: [redacted]

Cell:

List individuals that will be assisting with the activity, DOB is required. *(Attach additional page if needed)*

	Legal Name	Date of Birth (YY/MM/DD)		Legal Name	Date of Birth (YY/MM/DD)
1)	[redacted]	[redacted]	6)	[redacted]	[redacted]
2)			7)		
3)			8)		
4)			9)		
5)			10)		

4. SAMPLING PROGRAM - METHODS/LOCATION/SPECIES/DETAILS/OBJECTIVE etc..

Details of where the sampling is to occur, and the gear being used (*Provide detailed information including when, where, and how much sampling will occur)*

Name of River/Stream/Lake/Creek *(use a separate line for each waterbody)* **Watershed codes:** *search http://cmnmaps.ca/fiss_yukon/*	Detail of each sampling method *(ie. #trap nights, electrofishing seconds, # and duration of net sets, mesh size, etc. per sampling site etc. Also specify details of multiple sampling periods if applicable)*
See attached.	

Include species and life stage. Specify planned upper limit of sample size, maximum number and species of specimens that will be retained (if any). (Details not provided in specified fields, to be completed in "Additional Details" below.)

Species *(attach additional page if needed)*	Life stage	# of Fish Sampled	# of Fish Retained	# Estimates of Mortalities	Specify location of all mortalities and/or # retained
Arctic grayling	subadult/adult	200	0	5	
Arctic grayling	juvenile	200	0	10	
Slimy sculpin	subadult/adult	200	15	25	5 Peel w/s, 5 Bell w/s, 5 Whitestone w/s
Round whitefish	subadult/adult	100	0	10	
Lake whitefish	subadult/adult	100	0	10	
Longnose sucker	subadult/adult	100	0	10	

Details (Explain the purpose of retaining mortalities and/or lethal samples):	For the 15 retained slimy sculpin, the purpose is to provide DNA samples (fin clips) for the University of Montana to identify additional potential conservation units (subspecies, species) for a North America wide project. These individuals will ideally be chosen from any incidental mortalities and will only be retained in the event of no incidental mortalities. If there are any incidental mortalities of other species they will also have fin clips submitted to support this initiative.

Additional details (attach additional page if needed).

Include as much detail as possible including your research activities, methods of collection provide details, disposition of the specimens details of regarding release methods and location, and precautions that will be taken to avoid fish mortality. Provide information on handling of non target species if appropriate. etc..

Sites will be chosen to cover the spatial extent of the Project Area to provide a general understanding of fish distribution in different ordered streams. Each stream site will have a Site Card completed as well as fish sampling and in-situ water quality will be taken. Fish sampling will mostly be conducted using electrofishing methods, with beach seining where necessary on 4th or 5th order streams. Electrofishing effort will be approximately 100-300 meters and for a minimum of 400 seconds in order to adequately sample each site. The length of stream sampled will be proportional to the stream width. Sites will be sampled a minimum of 100 m upstream from the nearest confluence. In-situ water quality will be taken at each site, which includes the collection of temperature (degrees Celsius), pH, dissolved oxygen (mg and %), and specific conductivity (µS/cm). All fish captured will be identified to species and enumerated; up to 10 individuals from each species caught will be measured at each site before being returned to the water. Handling and air exposure will be kept to a minimum for all fish.

Footnotes:
* Scientific Purposes includes: Salvage (for fish collection associated with in-stream works etc.); Environmental Impact assessment (pre and/or post development project monitoring); Inventory (species abundance and distribution and/or presence/absence study)
** Experimental Purposes: Research (i.e.. fish collection as part of a experimental procedure, or research to determine how fish populations respond to habitat manipulations)
*** Educational Purposes: Training
**** Public Display Purposes: Samples for display purpose

Applications are to be submitted to:

PRIVACY NOTICE STATEMENT
The information you provide on this form is collected under the authority of the Fishery General Regulations for the purpose of issuing a licence for scientific, experimental, educational or public display purposes. The information may be used for program planning or management, reporting, audit, administration purposes or disclosed to other government departments or agencies, within other divisions or branches of the institution, with provincial, territorial or foreign government or First Nation organizations as applicable. Failure to provide this personal information may result in your licence being denied. You have the right to the correction of, access to, and protection of, your personal information under the Privacy Act and to file a complaint with the Privacy Commissioner of Canada over DFO's handling of your information. Personal information collected through the processing of your application is described in DFO Personal Information Banks and can be accessed and assessed for accuracy. For more information visit Info Source www.infosource.gc.ca.

5. RELATED LINKS INFORMATION ETC

Collection Period: Sensitive timing periods in aquatic environments in Yukon and transboundary waters can be found at: http://www.dfo-mpo.gc.ca/pnw-ppe/timing-periodes/index-eng.html. If you plan to sample using instream methods during sensitive periods, we suggest you describe means by which you will mitigate any negative effects.

Transfer or Transplant of Live fish/eggs/milt: Any transfer of live fish into fish habitat and transfer of live fish to a fish rearing facility, requires a permit from the Federal/Provincial/Territorial Introductions and Transfers Committee. Applications and contacts can be found at:
BC - http://www.pac.dfo-mpo.gc.ca/aquaculture/licence-permis/intro-trans/process-processus-eng.html
Yukon – http://www.pac.dfo-mpo.gc.ca/yukon/trans-eng.html

Species At Risk: Research into any species listed in the Species At Risk Act (SARA) requires a permit issued under SARA. Application forms can be found at: http://www.dfo-mpo.gc.ca/species-especes/permits-permis/permits-eng.htm

Canadian Council on Animal Care (CCAC): DFO is a member of the Canadian Council on Animal Care (CCAC) and has committed at the Ministerial level to follow the entire CCAC program in Departmental activities in research, teaching and testing with vertebrate animals. Nearly all universities and colleges in Canada follow this program as well. It is expected that if DFO financial or human resources are involved in the work under this requested licence, or if the applicant is based at an institution having a CCAC-accredited Animal Care Committee, then evidence of an approved Animal Use Protocol (AUP) will be submitted with this application, and CCAC guidelines will be adhered to in any work with live vertebrates. The issuing authority for this licence accepts the CCAC's exemptions for certain animal-use activities as not requiring an approved AUP. More information about the CCAC program is at *www.ccac.ca.*

Note: - Use of carbon dioxide/CO2 (e.g. Alka-Seltzer tablets) to immobilize fish for sampling should not be done without a continuous supply of oxygen, with levels of both gases monitored and regulated.
- Clove-oil products are not regulator-approved in Canada, as a fish anaesthetic.

Aquatic Invasive Species: To prevent the introduction of aquatic invasive species there are a few simple things that can be considered:
a) Before leaving an area: Drain water from boat, trailer and gear, remove all plant parts and mud and.
b) before entering another water body: Wash all your gear including waders with soapy water.

Longnose sucker	sub adult/adult	100	0	10

APPENDIX 2-A-10. May 5, 2021, Meeting Summary

FIRST NATION OF NA-CHO NYÄK DUN AND CHANCE OIL AND GAS MEETING

Date: May 5, 2021

Location: Microsoft Teams

Attendees:

First Nation of Na-cho Nyäk Dun:

[redacted] Consultant

Chance Oil and Gas Limited:

[redacted], President
[redacted], VP Government and Community Relations
[redacted], Regulatory, Environmental and Community Relations Coordinator

Hemmera:

[redacted], Human Environment Specialist
[redacted], Human Environment Specialist

Purpose and Objectives

The purpose of this meeting was for Chance to present a Draft Project Description of exploration activities proposed for the Eagle Plain Basin. Chance provided recent information and updates regarding baseline information gathered by consultants (Environmental Dynamics Inc. (EDI), Peer Solutions, Palmer) and Parties discussed next steps with community engagement and consultation schedules for the First Nation of Na-cho Nyäk Dun (FNNND).

Discussion:

The meeting opened with introductions and a welcome.

[redacted] Updates on the Eagle Plains Exploration Project, almost the same project as back in 2019, this presentation will highlight any changes that have happened since. Then we will go over next steps on developing the project proposal and community consultation and engagement schedules and preferences of the FNNND Government.

[redacted]: This presentation will cover what has changed following the 2019 project. We have also undertaken a number of field studies. Work on ecosystem characteristics was performed by EDI. Permafrost processes by Palmer Environmental. Technical design by Peer Solutions who is working on the seismic program.

DRAFT

EDI had several teams go into the field in 2019 and 2020. They were looking at bird studies, old seismic lines. Those old lines are a result of the technology at the time and the lack of understanding of the geology in the region. During the 50s to mid 80s there was 2D seismic activity. We did 3D seismic. Now, the footprint is much smaller today than 60 years ago. EDI looked at how old seismic lines. If those lines get any sort of use from animals, if they are regenerating, if humans use the area. EDI did fish and aquatic studies. They are trying to find the types of fish present. They obtained porcupine caribou information/data from the board; they have not finished their interpretation. EDI also visited quite a few spots. They are also using lidar which is a laser beam that is reflected off the surface and gives a good image of the landscape. Information useful for accessing sites and land and ecosystem classification. You can get a good snapshot of the area.

Palmer did a study to see where permafrost in the area is active and visited those spots along. Also visiting spots that could make access difficult. They are going back to get geotechnical data. Palmer's work is substantially done, besides what would need to be done following regulation processes. All this information will be available to share with everybody.

We did have a series of presentations in Mayo with Chief and Council, with Tr'ondëk Hwëch'in (TH), with Vuntut Gwitchin (VG), and various Gwich'in communities of the GTC in the NWT. All communities are aware of the proposal. We are trying to manage our land tenures. We are on track to submit to Executive Committee (EXCOM) in the fall, probably October. We will host meetings in the communities and bring consultants. We have started in Old Crow and will be moving to other communities in the next couple of months.

[redacted]: We have a timeline for this project. We want to ensure that we can get into the communities to address any concerns with ecological impacts. We have already informed the communities of the initial project, so this is not new. We have done a significant amount of work. We are excited to bring this baseline information into the community and formally submit this into an EXCOM. We are excited about sustainable development. We heard this is important from communities. We are doing this over the long term., A creative way to address concerns around sustainability. Compared to our Southern oil counterparts, we want to move slowly on drilling.

[redacted]: With the EDI studies, you have done more since the previous community meetings?

[redacted]: Yes, this will be available when we come to the communities with the consultants.

[redacted]: This could be possible in person with the new quarantine rules, we can share this information ahead of time.

[redacted] Start date?

[redacted]: We will cover engagement scheduling later in the meeting. Correction on engagement with FNNND. We met with FNNND technical experts. We did not meet with Chief and Council although they were informed of the meeting. Also, notes from today are being taken and will be sent to you after this meeting. Part of Hemmera's role is creating a record of this meeting to be reviewed and edited by FNNND and Chance.

[redacted]: I'm digging into FNNND files on this. The only thing I'm aware of is the 2019 engagement. Thank you for clarifying. I am in the process now of requesting how FNNND wants to deal with community meetings. A month ago, that they were very sensitive about people coming into Mayo. This is softening. I am trying to get clarification on community meetings.

[redacted]: That's great feedback. This will help inform our engagement activities moving forward. I'll put up the presentation.

[redacted]: This presentation will describe the exploration project proposal. None of this will be development but looking at what could possibly be developed in the future. The project itself is going to occur in an area of 2,400 km that is within the exploration permits Chance holds. This project includes 30 wells and shooting new seismic data. If we have any success on the drilling, it will move to flow testing. Flow testing for natural gas takes up to two months and up to two years if it's oil. It will help us assess potential development. We would dispose of the cuttings in the area. There should not be anything wrong with these cuttings. We are operating in an area of sedimentary rock. It has already been exposed to the elements and are benign. There will be construction of winter trails. If there is success and if it is oil, then we will look at having access year-round. Because it is exploration, we phrased it as "up to 30 wells". This is a program that is meant to be an area wide assessment with 30 wells, exploratory drilling, and 2D and 3D seismic activity. I can't tell you exactly where the well sites will be or what order.

[redacted]: The initial wells would be based on the old seismic data? Then based on those wells, you would do new seismic data?

[redacted]: There is data that we have access to that covers a broader area. That we can use to investigate the area of interest. Our 3D seismic only covers an area of what we need. We need 7x that. We will try the first wells and then see what is around and then go from there. It depends on results as we go. This map [redacted] referred to presentation], outlines the area of interest. It shows the traditional areas and settlements blocks of VG and TH. I'm not totally sure that this map shows the new arrangement between TH and VG. There are 3 significant discovery licences. They are outlined in the yellow: natural gas discoveries between 1960 and 1980. They have oil and natural gas there. Dempster Highway did not exist, getting there was hard. All the discoveries made had value. SDL 021 and 020 overlaps FNNND traditional territory. There are 3 suspended wells at SDL 020 and 1 suspend well at SDL 021.

None of the activity we are talking about will occur on settlement land. Any question?

[redacted]: No.

[redacted]: Exploration drilling would progress on a small scale, such as 1 or 2 wells during operating season. There may be some reasons that we drill in the summer if there is some opportunity for access. 1 drilling rig could give us 3 or 4 wells per year. For assessment purposes, that is close enough to an estimate as we'll get. The drilling locations will be selected on high ground. Which means it is better for permafrost. We will do our best not to be down in the valley bottoms where it is more difficult to operate. We will avoid any ecologically sensitive areas; we will avoid heritage areas. We 've got quite a bit of information covering heritage since 1995. One of the criteria is that we drill away from water. We would likely not even be close. In this area, they are frozen bottom. We are not operating in an area with year-round flowing rivers. There is a whole bunch of regulatory acts that govern our behaviours. Any questions?

[redacted]: Who did the heritage studies?

[redacted]: It was Matrix at that time, now acquired by Stantec.

[redacted]: We worked with an archeologist at Matrix and [redacted], I think, from FNNND and citizens from VG. There is a full report on this. We requested a lot of this information.

[redacted]: Is this documented? It would be good if I could look through that and identify areas of further interests. The Traditional Knowledge would certainty be a factor in that FNNND wants considered.

[redacted]: Yes, we can make this an action item. It is definitely an area that input from FNNND will be critical.

[redacted]: [Going back to the presentation] New drilling techniques can reach a large area with a small footprint on the surface. Eagle Plains has experienced several tectonic related exploration projects. The terrain is a function of tectonic uplift. They tend to dip into peaks and valleys; you get subsurface hill tops of base rock. Oil and gas are less dense than water. Over time, the organic material gets cooked under the pressures of the rock and becomes natural gas.

[Reference to presentation on screen] On the left shows a well drilled in the winter 2019. When you are designing a well, you start with conductor pipe that gets you through to bedrock. This guides the first bit of drilling; the size of the surface hole has to be 25% of the entire depth. It is all designed to handle bit changes, the deeper you go the bigger well diameter. That photograph [reference to presentation on screen] is at our camp, it gives you an idea of what the rig will look like.

[redacted]: We can move right through; I am familiar with this.

[redacted]: The flow testing is longer because there is not much understood of the geology. In the case of natural gas, this test would not be as long as oil. We have given some thought into putting a small-scale distillation project, to sell in the Yukon to avoid trucking. Any questions?

[redacted]: No, you can move along.

[redacted]: There will be some infrastructure related to testing. We must depressurize what is coming up in the well. It gets separated and measured. Any fluids like water will be disposed. Any oil would be sold or trucked to the proper market. Likely this will either be somewhere within the Yukon or a terminal in Vancouver to be shipped away. We will do our best to conserve natural gas. The drill mud is also high pressure. The seismic is an important part of the project. It's very good for imaging. It is much harder to see the lines made today than in the 60s. You can barely see the lines with the seismic work that we did recently.

For the workforce, if we reach peak human employment, we will have an overflow of more than 70 people in the camp. The work rotations will consist of 20 days on and 10 days off, day and night shifts. We can only do one activity / the other (drilling or seismic) with the workforce size. At well sites we will need to have areas for campers for workers to warm up during shifts.

Unsuccessful wells will be abandoned and allowed to regenerate naturally. Mix bury cover sites would be left there to recover. We predict there will be little to no ground water leaching due to thick frozen rock between the area of interest underground and the active layer of permafrost. Mixed bury cover has been used widely in the North Yukon. It is not a new technique. We will follow Alberta's guidelines on this. They

DRAFT

have the most extensive guidelines. We hope to get screened by executive committee this Fall, to manage the tenure clock we have on the permits.

[redacted]: Not quite sure who is involved in the pre-screening process as far as regulators go. I was involved in YESAB's creation. There should be regulators involved from the start, but we have seen that they often get involved too late. Have you had a chance to work with them/regulators on this?

[redacted]: We have been in contact with [redacted] from Yukon Government. Have met with them several times.

[redacted]: We do rely on them to make these connections. They've been given documents on this already.

[redacted] Sometimes First Nations go off the recommendations of the regulators.

[redacted] For engagement, Hemmera provides support for Chance on all their engagement activities and provides project management for all their project proposal. We do have draft project description. It was shared broadly with First Nations back in 2019. We are adding information to feed in what we learned coming into the Designated Office (DO)project. We are also working on socio-economic components on this project. EDI is the major workforce for the ecological components. We are working on updating the drafted project proposal, compiling all baseline studies, and working on development of those sections. We are mostly at the draft project description phase. We'll be sharing other information with First Nations as well. We have not started drafting the effects assessment yet. We initially engaged with First Nations in 2019. However, that was put on pause. We re-directed efforts to the DO. Now we are starting again and kicking off engagement activities with FN Governments and Citizens. This part of YESAA's requirements of Chance. Regarding completing the project proposal, we have created a tentative engagement schedule that covers now until the Fall. It hits certain themes between now and then. Those themes include summary of project description, concerns, and later we will be discussing mitigations etc. We do understand this a tight timeline. We'll share this memo with you. It's also been shared with YG, VGG, and TH.

[redacted] The FNNND is completely swamped. The memo will help me get others to put some focus on this. Depends on what Mayo and FNNND feel on community meetings. First Nation Government doesn't want to do much until community meetings are held.

[redacted] That is amazing information for us to have to plan these meetings/engagement. Our preference is to do something face to face.

[redacted] So far, it's been going good in Old Crow. We do it in an open setting, like a school gym, where we can space out. We still have to consider the time frame of our permits. We're obligated under the dispositions. We certainty are open to looking at trying to fit in and provide all the necessary information to the community and FNNND citizens. This would include meetings with the Renewable Resource Council. We would like them to be able participate in this discussion. We would like to have a presentation with the Porcupine Caribou Management Board.

[redacted]What about the idea of doing something like today with the Renewable Resource Council (RRC) and FNNND Lands technicians. In zoom meeting, if they are comfortable with zoom meetings. That will give some community representatives an idea of what is going on. Then when we start in person meetings, it can be community driven.

DRAFT

[redacted]: Since 2019, it has been hard to pin down the First Nation Governments. If you could facilitate that, it could help. I remember there was an Elder from the RRC in Mayo who always comes to our meetings and requests more information. It would be great to answers their questions.

[redacted]: Once I get this engagement memo and I speak with leadership, we can initiate things.

[redacted]: That would be perfect and help us accelerate to the next step. Getting feedback from RRC and FNNND Lands Tech staff will help us develop our proposal and make it better.

[redacted]: We can look at tentative openings and run it by you guys.

Action Items/Next Steps:

- Chance/Hemmera will send baseline information as it becomes available.
- Chance/Hemmera will send updated project description when it is available.
- Hemmera will send 2021 Engagement Schedule Memo
- [redacted] to seek engagement guidance from FNNND Chief and Council
- Hemmera and [redacted] to set up meeting with Mayo Renewable Resource Council and FNNND Lands staff
- Hemmera/Chance to send Matrix Heritage Report

1.0 INTRODUCTION

This report demonstrates implementation of the *First Nation of Na-Cho Nyäk Dun and Chance Oil and Gas Limited Engagement and Communication Plan* (Plan) (see **Appendix A**) finalized on August 8, 2018. It summarizes discussions held between First Nation of Na-Cho Nyäk Dun (FNNND) and Chance Oil and Gas Limited (Chance) between June 1, 2020 and May 31, 2021. The purpose, objectives, and outcomes of each discussion are described below in order to fulfill the requirements of Ministerial Order (MO) 2018/42 (see **Appendix B**) issued to Chance on August 30, 2018.

2.0 BACKGROUND

The development of communications and engagement plans began with Order in Council (OIC) 2016/169. OIC 2016/169 required Chance to file a First Nations communication and engagement plan with the Minister of Energy, Mines and Resources in order to extend tenure on their northern permits: 0005, 0006, 0007, 0008, 0009, 0010, and 0011. Chance complied with OIC 2016/169 and received their tenure extension.

Chance subsequently received MO 2017/37 when applying for tenure extension on six of eight southern permits: 0012, 0013, 0014, 0015, 0016, and 0017. MO 2017/37 required Chance to revise, in consultation with affected First Nations, the consultation and engagement plan filed under OIC 2016/169. The affected First Nations listed in MO 2017/37 were Vuntut Gwitchin First Nation, Tr'ondëk Hwëch'in, First Nation of Na-Cho Nyäk Dun, Gwich'in Tribal Council, and Tetlit Gwich'in Council.

FNNND and Chance collaboratively developed their Plan through a series of in-person meetings and conference calls. Hemmera was retained by Chance in November 2017 to facilitate the development and completion of the communications and engagement plans with the affected First Nations and facilitated all discussions between FNNND and Chance.

Chance and FNNND submitted their finalized Plan to Minister Ranj Pillai on August 28, 2018. To satisfy their obligations under MO 2017/37, Chance filed a total of four communications and engagement plans. All four plans were approved by the Minister and Chance received a five-year tenure extension on the six southern permits.

A condition of the five-year tenure extension, issued via MO 2018/42, required that Chance submit annual reports summarizing actions taken to implement each communications and engagement plan.

See **Appendix C** for a map of Chance's current permits.

3.0 ENGAGEMENT AND COMMUNICATION PLAN IMPLEMENTATION SUMMARY

3.1 Overview

Parties have advanced discussion on Chance's proposed Eagle Plains Exploration Project and Chance's proposed project for Well Maintenance and Extended Flow Testing. The following sections provide separate summaries of engagement activities that occurred for Chance's projects between June 1, 2020 and May 31, 2021.

DRAFT

3.2 Summary of Engagement – Well Maintenance and Extended Flow Testing Project

Initial notification was sent to FNNND on May 25, 2020. That package included a high-level overview of the project (e.g., project activities, components, goals, outcomes), the regulatory submissions Chance would be making, a brief introduction to Hemmera and its role, as well as a request to discuss any concerns the affected party may have and an offer to arrange a conference call should they so desire. Also included was a 4-page project summary and map of the project location.

Additional communications followed on June 9, June 24, and July 20, 2020. Chance did not receive feedback from FNNND while the project was being refined or when the project proposal was being drafted. A draft of the Project Proposal was shared with FNNND July 24, 2020.

Following additional conversations with the regulator (Government of Yukon), Chance was required to make changes to its project design. On August 7, 2020, FNNND was provided notice that revisions were being made to the project and that additional information would be forthcoming. A revised project proposal was provided, via email, to FNNND on August 28, 2020, along with a cover letter summarizing the revisions and providing a rationale for each.

Chance submitted an initial project proposal to YESAB on September 11, 2020. However, after further consideration, Chance determined that additional changes were required. On November 2, 2020, via email, Chance notified FNNND that it had decided to withdraw its project proposal from YESAB and submit a revised version. In that email Chance stated that once a revised proposal had been drafted, Chance would notify FNNND by sharing a draft and requesting a meeting to discuss the changes further, and Chance stated at that time that after it had the opportunity to discuss those changes with FNNND, the project proposal would be finalized and resubmitted to the Dawson Designated Office.

The revised draft project proposal was provided via email to FNNND on November 19, 2020, and in that email Hemmera indicated that Chance would be submitting the proposal to YESAB the following day. On November 20, 2020, Hemmera informed FNNND that Chance would delay submission until the following week. That same day, a FNNND representative replied indicating the draft was received and being reviewed.

New FNNND staff were assigned the Chance file, and, on November 25, 2020, they requested previous versions of the proposal in order to better understand the project's evolution. On behalf of Chance, Hemmera provided previous version of the proposal and an overview of changes/revisions that had taken place. Hemmera also provided additional context with respect to Chance's larger portfolio and proposed projects and engagement activities.

To allow for additional revisions, Chance's submission to YESAB was delayed until December 24, 2020.

3.3 Summary of Engagement – Eagle Plains Exploration Project

Between June 1, 2020 and May 31, 2021, Chance and FNNND have had only one meeting pertaining to the Eagles Plains Exploration Project.

3.3.1 Meeting Summaries

Date: May 5, 2021

DRAFT

Location: Microsoft Teams
Attendees: FNNND Consultant, Chance Management, Hemmera

Chance last engaged FNNND on the Eagle Plains Exploration Project in 2019 and the purpose of this meeting was for Chance to re-initiate engagement. Chance presented a high-level overview of exploration activities proposed for the Eagle Plain Basin. The presentation also highlighted any changes in project design that occurred since it had last been shared with FNNND in 2019. The presentation went over the layout of well sites, drilling methods, seismic program, and workforce. Chance also provided recent information and updates regarding baseline information gathered by Chance's consultants (Environmental Dynamics Inc (EDI), Peer Solutions, Palmer), and Parties discussed next steps regarding FNNND's preferences for community engagement and consultation (e.g., schedule, format).

Chance stated that their timeline was aiming for a Fall 2021 submission to Yukon Environmental and Socio-economic Assessment Board (YESAB) and that Chance was working towards getting into the communities in order to learn about, and address, any concerns related to ecological impacts. FNNND asked if more studies had been completed by EDI since Chance had last spoken to the community. Chance confirmed that EDI has conducted additional studies (e.g., fish sampling, linear features study) and that they would be shared with FNNND as they are completed.

Chance and FNNND discussed the proposed seismic program. Chance explained that current seismic data covers a broad area, but has limitations. Chance needs to investigate/target areas of interest and subsequently requires approximately seven times the 3D data that is currently available. Chance confirmed that none of its proposed activities would take place on settlement land. FNNND asked about heritage studies and Chance stated that it had completed a heritage study previously and that at the time Chance has worked with Joella Hogan from FNNND and Vuntut Gwitchin Citizens. Chance committed to sharing a copy of that previous report with FNNND. On the topic of regulations and submission to YESAB, FNNND asked if regulators were involved in the pre-screening. Chance replied that they have been in contact with Derek Fraser from Yukon Government.

Chance and FNNND discussed community engagement strategies. FNNND stated that they are very busy and requested that Chance share its proposed draft engagement schedule. FNNND suggested that Chance meet with the Mayo Renewable Resource Council and that the meeting potentially include FNNND Lands staff. FNNND stated they would speak with leadership to seek direction on engagement preferences moving forward. Chance was to send the revised project description and baseline studies as they become available.

3.3.2 Communication Log

The correspondence between Chance and FNNND is documented in the Engagement Log (see **Appendix D**).

4.0 PLANS FOR ONGOING ENGAGEMENT AND NEXT STEPS

No additional engagement activities are expected for the Well Maintenance and Extended Flow Testing Project while it is undergoing YESAB's review.

FNNND and Chance will continue to hold discussions at regular intervals as Chance develops its project proposal for the Eagle Plains Exploration Project.

DRAFT

Upcoming engagement activities for the Eagle Plains Exploration Project are expected to involve the following:

- Sharing baseline data
- Meetings between FNNND technical staff and Chance's technical consultants preparing the project proposal for proposed Eagle Plains Exploration Project
- Community engagement events for FNNND citizens

DRAFT

5.0 APPROVAL OF IMPLEMENTATION SUMMARY

FNNND and Chance have reviewed this report and agree to its contents as an accurate summary of the engagement activities carried out between June 1, 2020 and May 31, 2021.

Re: Submission of the First Nation of Na-Cho Nyak Dun and Chance Oil and Gas Limited Engagement and Communications Plan

Dear Minister [redacted]

I am pleased to inform you that the First Nation of Na-Cho Nyak Dun and Chance Oil and Gas Limited (Chance) have concluded our work to develop a framework to facilitate effective and meaningful communications and engagement between ourselves and Chance. The framework captured in the enclosed Engagement and Communications Plan establishes a foundation for a respectful relationship, that we will cooperatively address Na Cho Nyak Dun's capacity and resourcing needs to implement the framework as we continue to work together to ensure the environment is protected and development occurs in a sustainable manner.

Please accept the enclosed Plan for the purposes of Ministerial Order 2017/037. We trust that the Plan will be of satisfaction to the Minister.

I look forward to the next step in the process related to the government to government Consultation regarding the possible renewal or further extension of the oil and gas leases related to this project.

Sincerely,

[redacted]

Chief [redacted]

First Nation of Na-cho Nyak Dun and Chance Oil and Gas Limited Engagement and Communication Plan

1.0 Introduction

Chance Oil and Gas Limited (Chance) is an oil and gas exploration company that holds permits to perform oil and gas exploration activities in the Eagle Plain basin of Yukon Territory, Canada. As part of Chance's exploration program, Chance seeks to develop engagement and communication plans with all the First Nations that are potentially affected by Chance's exploration program activities. Permits 14, 15, 19, and 20 fall within or partially within the First Nation of Na-cho Nyak Dun Traditional Territory and Chance is seeking to engage the First Nation of Na-cho Nyak Dun (FNNND) on its activities within these permits.

2.0 Purpose

This document serves as an Engagement and Communication Plan (Plan) to provide a mutually agreed upon framework to support collaborative and effective engagement and communication between Chance FNNND now and into the future. This Plan incorporates and aligns with FNNND's *Cooperative Engagement Process*.

3.0 Relationship

Chance and FNNND will execute this Plan according to the following principles:

- Transparency and openness;
- Timeliness;
- Integrity;
- Adaptive Management;
- Mutual respect; and
- Working towards trust and understanding of one another.

These principles are adapted from the FNNND *Guiding Principles for Mining Interests* and from Chance's corporate values.

4.0 Key First Nation of Na-cho Nyak Dun and Chance Connections

Engagement and communication between Chance and FNNND will be generally associated with the proposed works and potential effects associated with Chance's oil and gas exploration program and potential opportunities (via training, employment, contracting, and other community investments), as well as any topics or issues identified through engagement and communication associated with Chance's proposed activities. This section of the Plan identifies the key contacts related to these overarching engagement and communication themes. Key representatives involved in engagement and communication are expected to be as follows:

- Chief and Council;
- FNNND Government department officials and advisors;
- FNNND Business Development agencies;
- FNNND Citizens and communities at large; and
- Proponent Management and designated staff and advisors.

The following table lays out the key engagement and communication topics, in no particular order, and associated key contacts for both Chance and FNNND:

Table 1 - Key Engagement and Communication Topics and Leads

Role or Subject Matter	FNNND Key Contact	Chance Key Contact
Project Lead	• Lands & Resources Manager (as described in the FNNND *Cooperative Engagement Process)*	• Vice President of Government and Community Relations
Culture and Community (includes Traditional Knowledge and Traditional Land Use, social, health, and other "human environment" subjects)	• Lands & Resources Manager	• Vice President of Government and Community Relations, Regulatory, Environmental and Community Relations Coordinator
Engineering and Geology	• Lands & Resources Manager	• Chief Executive Officer, President
Environmental	• Lands & Resources Manager	• Vice President of Government and

Role or Subject Matter	FNNND Key Contact	Chance Key Contact
(includes water, aquatic environment, wildlife, plants, and other environmental subjects)		Community Relations, Regulatory, Environmental and Community Relations Coordinator
Opportunities (includes community investment, training, education, contracting, employment, and other business opportunities)	• Lands & Resource Manager	• Chief Executive Officer, President
Agreements and Capacity Funding	• Lands & Resources and Negotiations Teams (as described in the FNNND *Cooperative Engagement Process*)	• Chief Executive Officer, President

5.0 Engagement and Communication Methods

Chance and FNNND will employ the following engagement and communication methods for specific correspondence:

- In person meetings;
- Email;
- Sharing Power Point Presentations (to support in person meetings);
- Sharing reports (as requested and as required) and;
- Telephone correspondence (teleconferences and less formal phone calls).

Engagement and communication methods that support general communication of Chance's activities are as follows:

- Chance newsletters; and
- The website for Chance Oil and Gas Limited.

Engagement and communication meetings will be executed in the following manner:

1. Chance or FNNND will request a meeting in writing to the other party according to the connections iterated in Table 1;
2. The parties to meet will develop the agenda collaboratively;
3. The party requesting the meeting will develop supporting materials (collaboratively, where possible), and share those in advance of the meeting; and
4. The meeting will take place in a mutually agreeable location.

The above general process applies to meetings with subject matter leads (Table 1) as well as meetings with Citizens and communities at large.

Through engagement with FNNND, Chance understands that there are existing communications protocols between FNNND, Tr'ondëk Hwëch'in, and Vuntut Gwitchin First Nation through the Northern Chiefs Accord. In keeping with the relationship principle of mutual respect, Chance will work within these existing communications protocols where applicable and as directed by FNNND.

The following documentation sharing and review protocols support the methods described above:

- Confidentiality of the meeting minutes will be discussed and established in advance of the meeting; i.e. if a meeting is to not be included in the record that will be submitted to regulators and assessors, it is the responsibility of both parties to discuss and agree to this prior to the meeting beginning;
- Meeting minutes taken by Chance will be sent to FNNND within two weeks via email; review and comment on these meeting minutes by FNNND through tracked changes, or some method agreed to by both parties, will be provided via email within 30 days of FNNND receiving the meeting minutes. Should FNNND require more time to review the meeting minutes, FNNND will notify Chance by email within two weeks of receiving the minutes. No response by FNNND to Chance's email providing meeting minutes within the 30 days will be interpreted as general acceptance of the meeting minutes by FNNND;
- Action items and meeting outcomes will be logged during meetings and reviewed by both parties at the end of the meeting to ensure that there is general agreement on the list of actions and parties responsible for those actions. The list of action items and meeting outcomes will be provided with the meeting minutes;
- Chance and FNNND will agree upon and use a file sharing platform to facilitate sharing of large files, such as Power Point presentations and reports; and,
- Should Chance or FNNND employ a third party for records development and management, the third party will follow the process iterated above for recording and providing meeting minutes.

6.0 Records Management

Summarized records of engagement and communication between Chance and FNNND will be kept in a records log. The Chance will ultimately submit the items below to regulators and assessors for review if and when a potential project is assessed in the future:

- Meeting agendas;
- Meeting minutes (finalized versions as described in section **5.0 Engagement and Communication Methods);**
- Invitee/Attendees lists and/or meeting sign-in sheets;
- Records log, which will include summaries of the following:
  - In person meetings;
  - Phone calls and teleconferences;
  - Incoming and outgoing emails between Chance and Chance's representatives and FNNND representatives;
  - Attachments to the above noted incoming and outgoing emails;
- Reports provided to FNNND by Chance and reports provided to Chance by FNNND for review and consideration for engagement and communication purposes; and
- Copies of Power Point presentations delivered by Chance to FNNND for engagement and communication purposes.

To ensure that there is a mutual level of comfort with the records log and materials to be submitted for assessment, Chance and FNNND will collaboratively review and agree to the records log and materials prior to submission to any regulator or assessor.

7.0 Adaptive Management of the Engagement and Communication Plan

Chance and FNNND will review and assess the effectiveness and success of this Plan on at least a 6-month basis. There will be a meeting to check in on the progress made by both parties in implementing the Plan within 3 months of the Plan first being agreed to and implemented, and a schedule for review of the Plan will be developed at that time.

APPENDIX B
Ministerial Order 2018/42

DRAFT

YUKON

CANADA

MINISTERIAL ORDER 2018/ 42

OIL AND GAS ACT

Pursuant to the *Oil and Gas Act*, the Minister of Energy, Mines and Resources orders

1 In this Order

"subject permit" means each of the following oil and gas permits held by Chance Oil and Gas Limited:

(a) oil and gas permit No. 0012,

(b) oil and gas permit No. 0013,

(c) oil and gas permit No. 0014,

(d) oil and gas permit No. 0015,

(e) oil and gas permit No. 0016,

(f) oil and gas permit No. 0017. « *permis visé* »

2 The renewal term of each subject permit is extended by five years (so that it ends on August 30, 2023).

3 The resulting total length of the initial term and the renewal term of a subject permit is 16 years.

CANADA

ARRÊTÉ MINISTÉRIEL 2018/42

LOI SUR LE PÉTROLE ET LE GAZ

Le ministre de l'Énergie, des Mines et des Ressources, conformément à la *Loi sur le pétrole et le gaz*, arrête :

1 La définition suivante s'applique au présent arrêté.

« permis visé » Les permis suivants de pétrole et de gaz détenus par Chance Oil and Gas Limited :

a) permis de pétrole et de gaz nº 0012;

b) permis de pétrole et de gaz nº 0013;

c) permis de pétrole et de gaz nº 0014;

d) permis de pétrole et de gaz nº 0015;

e) permis de pétrole et de gaz nº 0016;

f) permis de pétrole et de gaz nº 0017. "*subject permit*"

2 La durée du renouvellement de chaque permis visé est prolongée de cinq ans, de façon à ce qu'elle se termine le 30 août 2023.

3 La durée totale d'un permis visé, y compris la durée initiale et la durée du renouvellement, est de 16 ans.

2018/42

4(1) In this section

"first nations communications and engagement plan" means the plan filed under O.I.C. 2016/169 and revised in accordance with M.O. 2017/37. *« plan de participation et de communication avec les premières nations »*

(2) It is a condition of this Order that Chance Oil and Gas Limited must file annual reports with the Division Head, in accordance with subsection (3) and to the satisfaction of the Division Head, about the implementation of the first nations communications and engagement plan.

(3) For the purposes of subsection (2), Chance Oil and Gas Limited must file

(a) the first annual report on or before July 31, 2019, in respect of the period beginning on September 1, 2018, and ending on May 31, 2019; and

(b) each subsequent annual report on or before July 31 of each year in respect of the period beginning on June 1 of the preceding year and ending on May 31 of the year in which the report is to be filed.

Dated at Whitehorse, Yukon,
~~Oc~~ August 30th 2018.

4(1) La définition suivante s'applique au présent article.

« plan de participation et de communication avec les premières nations » Le plan déposé en vertu du Décret 2016/169 et révisé en conformité avec l'Arrêté 2017/37. *"first nations communications and engagement plan"*

(2) À titre de condition du présent arrêté, Chance Oil and Gas Limited dépose des rapports annuels auprès du chef de division, en conformité avec le paragraphe (3) et à la satisfaction du chef de division, concernant la mise en œuvre du plan de participation et de communication avec les premières nations.

(3) Pour l'application du paragraphe (2), Chance Oil and Gas Limited dépose :

a) le premier rapport annuel au plus tard le 31 juillet 2019, pour la période débutant le 1er septembre 2018 et se terminant le 31 mai 2019;

b) chaque rapport annuel subséquent, au plus tard le 31 juillet de chaque année pour la période débutant le 1er juin de l'année précédente et se terminant le 31 mai de l'année au cours de laquelle le rapport doit être déposé.

Fait à Whitehorse, au Yukon,
le August 30th 2018.

E00276	May 22, 2019	Email	Out	First Nation of Na-cho Nyäk Dun	[redacted]	[redacted]	[redacted]	Site Visit/Field Work Engagement/Consultation	Had sent e-mail to [redacted] but as she is no longer with NNDFN, was transferred to [redacted] by front desk, so assuming Josee has taken on responsibilities of [redacted] position. Following up about field work for summer. Working with Hemmera to set up a meeting with NNDFN to provide an update and present Project Description for June 10th. Required to consult under geoscience license guideline to inform VGG, NNDFN and Tetlit Gwich'in Council that field work is planned July 10-24, 2019. Will be based out of Eagle Plains Lodge with helicopters. Will be flying to remote outcrop locations through out Eagle Plains Basin to extract rock samples with geological hammer. No mechanical tools will be used.
E00277	May 23, 2019	Email	In	First Nation of Na-cho Nyäk Dun	[redacted]	[redacted]	[redacted]	Meeting Coordination/Planning	Josee is acting in position until further notice and appreciates communication about the project. June 10th marked on calendar. [redacted] can contact Colleen to make arrangements. Let [redacted] know if needing any field works for summer field work.
E00278	May 23, 2019	Email	Out	First Nation of Na-cho Nyäk Dun	[redacted]	[redacted]	[redacted]	Meeting Coordination/Planning	Thank you for your e-mail, will coordinate with [redacted] for June 10th Meeting.
E00454	June 3, 2019	Email	Out	First Nation of Na-cho Nyäk Dun	[redacted]	[redacted]	[redacted]	Meeting Coordination/Planning	Coordinating the June 10 meeting with Chance. I just want to confirm we have a room available. We will have handouts, so we won't need a projector. Could we arrange transportation to and from the airport for the meeting with you?
E00455	June 3, 2019	Email	In	First Nation of Na-cho Nyäk Dun	[redacted]	[redacted]	[redacted]	Meeting Coordination/Planning	Pick up at the airport is not a problem. I booked the Multi purpose room. What time is the meeting going to be at? And do you have posters to put up? Anything else I need to do?
E00456	June 3, 2019	Email	Out	First Nation of Na-cho Nyäk Dun	[redacted]	[redacted]	[redacted]	Meeting Coordination/Planning	Thank you for booking the room and arranging a ride from the airport. We will have a few posters to put up and will have hand out material. Greg, what time did we decide for the meeting?
E00459	June 3, 2019	Email	Out	First Nation of Na-cho Nyäk Dun	[redacted]	[redacted]	[redacted]	Meeting Coordination/Planning	The meeting will be 10-12. We're wondering if everyone who is joining us for the meeting would like to get lunch after. Is there a restaurant in town we could all go to or would it be possible to arrange catering?
E00460	June 3, 2019	Email	In	First Nation of Na-cho Nyäk Dun	[redacted]	[redacted]	[redacted]	Meeting Coordination/Planning	I could arrange someone to cater. Is there a poster you want me to post around town?
E00461	June 3, 2019	Email	Out	First Nation of Na-cho Nyäk Dun	[redacted]	[redacted]	[redacted]	Meeting Coordination/Planning	I don't think we need posters around town. We will host a community even later and then need to post posters around town. For lunch, it will be 5 of us from Chance, and then those that attend from FNNND. Do you think the restaurant can accommodate a large group and where is it? Do you think that group would rather go out for lunch or have it catered?
E00471	June 5, 2019	Email	In	First Nation of Na-cho Nyäk Dun	[redacted]	[redacted]	[redacted]	Meeting Coordination/Planning Project Description/Activities	Catering would be best. I lined up a caterer for June 10.
E00265	June 6, 2019	Email	Out	First Nation of Na-cho Nyäk Dun	[redacted]	[redacted]	[redacted]	Meeting Coordination/Planning Project Description/Activities	Finalizing agenda and calendar invite for meeting between Chance and First Nation of Na-cho Nyäk Dun the following week
E00293	June 6, 2019	Email	Out	First Nation of Na-cho Nyäk Dun	[redacted]	[redacted]	[redacted]	Meeting Coordination/Planning	Meeting invitation for June 10, 10-1. This meeting is for Chance to present a Draft Project Description of exploration activities proposed for the Eagle Plain Basin. Additional agenda items include next steps with YESAB and the process for reviewing Na-cho Nyäk Dun Project Effects as well as the annual reporting required on the implementation of the Engagement and Communication Plan.
E00297	June 6, 2019	Email	In	First Nation of Na-cho Nyäk Dun	[redacted]	[redacted]	[redacted]	Meeting Coordination/Planning	Thank you, looking forward to meeting on June 10th.
E00319	June 6, 2019	Email	In	First Nation of Na-cho Nyäk Dun	[redacted]	[redacted]	[redacted]	Meeting Coordination/Planning	Confirming the orange room is reserved for meeting on June 10.
E00295	June 7, 2019	Email	Out	First Nation of Na-cho Nyäk Dun	[redacted]	[redacted]	[redacted]	Project Description/Activities Meeting Coordination/Planning	Draft Project Description and presentation for meeting attached. Please distribute to those attending the meeting. Will bring paper copies. Please provide an estimate of attendees.
E00420	June 7, 2019	Email	Out	First Nation of Na-cho Nyäk Dun	[redacted]	[redacted]	[redacted]	Meeting Coordination/Planning	We have a little portable projector and I'm wondering if you think we should bring it?
E00259	June 11, 2019	Email	Out	First Nation of Na-cho Nyäk Dun	[redacted]	[redacted]	[redacted]	Information Sharing Engagement/Consultation	Sending background information following meeting.
E00477	June 13, 2019	Email	In	First Nation of Na-cho Nyäk Dun	[redacted]	[redacted]	[redacted]	Information Sharing	[redacted] - can you please invoice Geoscience for the catering of this meeting. [redacted]
E00269	June 14, 2019	Email	Out	First Nation of Na-cho Nyäk Dun	[redacted]	[redacted]	[redacted]	Site Visit/Field Work Engagement/Consultation	Attached details for First Nation's participation in Chance's fieldwork this summer. Still finalizing dates and logistics. Role profiles are in attachment, and aiming to have dates finalized next week. Please give thought to potential participants.
E00478	June 14, 2019	Email	Out	First Nation of Na-cho Nyäk Dun	[redacted]	[redacted]	[redacted]	Engagement	[redacted]

E00261	June 17, 2019	Email	Out	First Nation of Na-cho Nyäk Dun	[redacted]	[redacted]	[redacted]	Engagement/Consultation Site Visit/Field Work	Dates set for participation in Field Surveys. Proposing following logistics for First Nation participation: 1) Each FN with territory overlapping project area can have up to two members participate 2)Work will be physically demanding, require hiking steep, rugged terrain and thick bush, requiring average or above-average fitness to participate 3)Limited spots for participants due to helicopter constraints ad availability at Eagle Plains Hotel, so please respond as soon as possible to [redacted] Hemmera) to confirm availability 4) Participants should arrive on start date, but not mandatory to stay for duration of field study 5) all travel, including flights, vehicle travel to Eagle Plains Hotel, ad stay in Hotel must be booked by the First Nation and billed to Chance. Table of Opportunities by date. Purpose of participation will be to observe fieldwork and gain first hand understanding of the research. Deadline for Vegetation Survey # 1 is June 19th.
E00254	June 24, 2019	Email	Out	First Nation of Na-cho Nyäk Dun	[redacted]	[redacted]	[redacted]	Fish Information Sharing	Attached notice letter regarding DFO licence application for Environmental Dynamics Inc's fish studies
E00256	June 24, 2019	Email	In	First Nation of Na-cho Nyäk Dun	[redacted]	[redacted]	[redacted]	Engagement/Consultation	Thank you for information on DFO Application. Please copy [redacted] on any future communication between NND and Chance.
E00257	June 24, 2019	Email	Out	First Nation of Na-cho Nyäk Dun	[redacted]	[redacted]	[redacted]	Engagement/Consultation	Confirming instructions to copy [redacted] going forward.
E00266	June 25, 2019	Email	Out	First Nation of Na-cho Nyäk Dun	[redacted]	[redacted]	[redacted]	Information Sharing Engagement/Consultation	Draft Summary of June 10 meeting in Mayo between Chance and First Nation Na-cho Nyäk Dun
E00314	June 27, 2019	Email	Out	First Nation of Na-cho Nyäk Dun	[redacted]	[redacted]	[redacted]	Fish Information Sharing	Revisions from EDI for their DFO Application, see Attached
E00483	July 9, 2019	Email	Out	First Nation of Na-cho Nyäk Dun	[redacted]	[redacted]	[redacted]	[redacted] Visit/Field Work	Have you had any interest for participation in the Chance field surveys? Below I've highlighted the surveys there's still time to participate in.
E00485	July 9, 2019	Email	Out	First Nation of Na-cho Nyäk Dun	[redacted]	[redacted]	[redacted]	Site Visit/Field Work	I corrected my highlighting below to include all the surveys at the end of July and early August. These are the surveys available to join
E00591	July 15, 2019	Email	Out	First Nation of Na-cho Nyäk Dun	[redacted]	[redacted]	[redacted]	Meeting Coordination/Planning Engagement/Consultation	We would like to meet with you and other interested government representatives on Aug 12 in Mayo if that works for you. My colleagues and our Hemmera advisors will be returning from the GA in Old Crow on Aug 10 via Dawson so it might make sense for us to continue our engagement discussions as we advance towards a YESAB submission early in 2020. We would rent a vehicle in Dawson and drive to Mayo for the meeting. Please let us know if this will work.
E00488	July 16, 2019	Email	Out	First Nation of Na-cho Nyäk Dun	[redacted]	[redacted]	[redacted]	Engagement Reports/OIC Requirements	Hemmera has prepared draft reports on the Implementation of the Communications and Engagement Plan for both VGG and Chance to review. This report summarizes meeting we have had since completing the plan. Please make any desired revisions to the document in tracked changes and send back to me to finalize. Once I have incorporated the changes, I willl send final versions to both parties to sign. Please have revisions in by July 26, then I will finalize, get them signed and submit to Yukon Government for July 31.
E00491	July 24, 2019	Email	Out	First Nation of Na-cho Nyäk Dun	[redacted]	[redacted]	[redacted]	Engagement/Consultation Meeting Coordination/Planning	I am following up on 2 items for Chance: the draft Communications and Engagement Plan Implementation Report, and a proposed meeting on August 13 in Mayo. Would FNNND like to provide feedback on the draft report? I'm looking for feedback by Friday. Chance team in Dawson Aug 12 and proposing travel to Mayo Aug 13. Chance would like to discuss project updates and a Cooperation Agreement template. FNNND also mentioned that meeting with Chief and Council might be good. Please let us know.
E00320	July 25, 2019	Email	Out	First Nation of Na-cho Nyäk Dun	[redacted]	[redacted]	[redacted]	Meeting Coordination/Planning	Following up about meeting on August 12th to discuss the exploration project and related discussions such as cooperation and capacity funding arrangements. Would like to change to August 13th, as there is a conflict on August 12 meeting with TH in Dawson. Are you able to meet with us August 13, in Mayo?
E00321	July 25, 2019	Email	In	First Nation of Na-cho Nyäk Dun	[redacted]	[redacted]	[redacted]	Engagement/Consultation Meeting Coordination/Planning	Inquiring why they are not meeting together with the First Nations, instead of separately.
E00322	July 25, 2019	Email	Out	First Nation of Na-cho Nyäk Dun	[redacted]	[redacted]	[redacted]	Engagement/Consultation Meeting Coordination/Planning	Chance would love to meet collectively with all the affected First Nations, but have not had indications from the various First Nation governments that they wish to continue gathering in All Party meetings. I do feel there is merit in meeting all together where Value Components of the Eagle Plains area are in common. Is it possible to meet with you and your colleagues on August 13 in Mayo? Would be driving from Dawson and returning to Dawson the same day.
E00500	July 25, 2019	Email	Out	First Nation of Na-cho Nyäk Dun	[redacted]	[redacted]	[redacted]	Engagement Reports/OIC Requirements	Attached are Chance's edits to the Draft Plan Implementation report

Reference	Date	Contact Type	In / Out	Organization	Author	Proponent/Proponent Rep	External Organization Names	Topic/Regarding	Meeting/Correspondence Summary
E00536	July 30, 2019	Email	Out	First Nation of Na-cho Nyäk Dun	[redacted]	[redacted]	[redacted]	Engagement Reports/OIC Requirements	Following up on FNNND Comments on Draft Implementation Report. I left a voice mail, and also followed up with Ronaldo yesterday, but have not hear back. Final report is due to YG tomorrow. Hoping you could review and sign off on the content. Please let me know if you would like to provide revisions by noon tomorrow so we revise with your feedback, otherwise I will submit to YG tomorrow at 4 pm.
E00543	July 31, 2019	Email	Out	First Nation of Na-cho Nyäk Dun	[redacted]	[redacted]	[redacted]	Engagement Reports/OIC Requirements	Hemmera has prepared reports for YG on behalf of Chance on the implementation of the Communications and Engagement Plan that FNNND and Chance completed last summer. It was previously discussed that both FNND and Chance would review this report and sign to demonstrate both parties agree to the report's contents. I have not heard back, and will submit the report to YG as a draft, however we welcome your feedback.
E00544	July 31, 2019	Email	Out	First Nation of Na-cho Nyäk Dun YG	[redacted]	[redacted]	[redacted]	Engagement Reports/OIC Requirements	Attached annual report on the Implementation of the FNNND and Chance Engagement and Communication Plan. This report has been reviewed and signed by Chance, but has not yet been reviewed or signed by FNNND despite our best efforts to send the draft report and follow-up. I will let you know if I receive any feedback.
E00346	August 9, 2019	Email	Out	First Nation of Na-cho Nyäk Dun	[redacted]	[redacted]	[redacted]	Meeting Coordination/Planning	Great to connect by telephone this morning. Following up to bring awareness to colleagues and advisors at Hemmera of the potential to meet with you and your new council on Aug 13 in Mayo. This will be an opportunity to introduce ourselves to those unfamiliar with Chance and to summarize what our exploration plans are. We are presently in Old Crow attending the GA but travelling to Dawson on Saturday to meet with TH officials. If you are able to arrange to meet with us, we will drive to Mayo Tuesday morning, so could be there about 10 am. We have to be back in Dawson for 3:30pm. Thanks for setting this up on short notice and we look forward to meeting with you and members of your council.
E00388	August 9, 2019	Phone Call	Out	First Nation of Na-cho Nyäk Dun	[redacted]	[redacted]	[redacted]	Engagement Meeting Coordination/Planning	Chance called NNDFN about meeting with Council at 10 am on August 13th, 2019. NNDFN said they would organize a group for the meeting and would call back on August 12th to confirm the meeting.
E00390	August 12, 2019	Phone Call	In	First Nation of Na-cho Nyäk Dun	[redacted]	[redacted]	[redacted]	Meeting Coordination/Planning	Chance called FNNND and FNNND confirmed they were unable to meet on August 13 and requested to meet at another time.
E00602	January 28, 2020	Email	Out	First Nation of Na-cho Nyäk Dun	[redacted]	[redacted]	[redacted]	Project Description/Activities Regulatory Process	Chance will be applying to the Yukon Government very shortly to extend the tenure of Exploration Permit 20. Application will be for maximum allowable under the Oil and Gas Act of 5 years. This permit has one suspended well at McParlon A-25 which we hope to use for fluid disposal of any produced water associated with the proposed exploration project. We are at an intermediate stage of discussions with the Manager of Oil and Gas Operations with Yukon to extend the suspended well status on the suspended wells at Eagle Plain. Manager has indicated hat Chance will need to do some physical assessments of the legacy wells to confirm the integrity of the wells before granting an extension. Assessments will require access to 3 suspended wells at SDL M-08, G-08, and J-19 and well as M-59 in order to do the work. A service rig, cement pumping equipment, and wireline services are expected to be used to conduct the assessments. Anticipate taking temperature measurements in wells to evaluate permafrost depth. The program is expended to take 1-2 months. This is a winter operation and will be done during the winter of 2020-2021 and may require Designated Office screening b y YESAB. We will provide more information as soon as we can.
E00646	March 23, 2020	Email	Out	First Nation of Na-cho Nyäk Dun	[redacted]	[redacted]	[redacted]	Information Sharing	Chance Oil and Gas (COG) has several initiatives on the go, some of which are time sensitive, and all require engagement with the affected First Nations. The following is a summary of these initiatives: 1.Application to the Yukon Government to get tenure extension on Exploration Permit 0020 which is set to expire on August 30, unless extended. This permit is located mostly in the Traditional Territory of the Vuntut Gwichin, but a portion is in the Secondary Use Area of the Tetlit Gwich'in and in the overlap area with the Na-cho Nyak Dun Traditional Territory. There is a suspended well in this Permit at McParlon A-25 which has ongoing value to COG. 2.There are several suspended wells at the Chance Significant Discovery License (SDL 022) and one at the Blackie SDL (SDL 021) which the Yukon Government requires COG to undertake some maintenance work. This activity will require an impact assessment by the Designated Office (DO) of YESAB in Dawson prior to permissions being granted by Yukon to undertake the work. The plan is to submit to the DO the program in the next month or so with the objective of being able to do the work over approximately a 6 week to two month period in the winter of 2020-2021. This is a regulatory requirement made by the Manager of Oil and Gas Operations with the Yukon Government. Importantly for your knowledge, there is no indication that these suspended wells have any problems, but they are wells that were drilled in the 1960's so the regulator has asked for work to be done in order to be able to continue the suspended status of these wells. 3.Continuing engagement with respect to the multi-well drilling and seismic data acquisition project that has been described to you in the past couple of years. A current map of COG landholdings is attached for your reference. In view of the COVID 19 outbreak, travel and face to face get togethers are not appropriate, if not prohibited, so we will have to make arrangements to exchange information in writing, electronically and by conference call. There is quite a geographic spread for all of us to manage and I look forward to hearing your preferences for engagement. Also, please forward this email to anyone I have missed who is working on the COG file.

E00682	June 9, 2020	Email	Out	First Nation of Na-cho Nyäk Dun	[redacted]	[redacted]	[redacted]	DO Project Meeting Coordination/Planning	I hope all is well, just following up from our program description from couple of weeks ago, if you have any question and comments, please contact us. if you would like us to arrange a call with your team, we would be happy to do so and provide you with an overview of the program.
E00796	June 9, 2020	Email	Out	First Nation of Na-cho Nyäk Dun	[redacted]	[redacted]	[redacted]	DO Project Meeting Coordination/Planning	I hope all is well, just following up from our program description from couple of weeks ago, if you have any question and comments, please contact us. if you would like us to arrange a call with your team, we would be happy to do so and provide you with an overview of the program.
E00797	June 24, 2020	Email	Out	First Nation of Na-cho Nyäk Dun	[redacted]	[redacted]	[redacted]	Engagement/Consultation DO Project	I wanted to reach out and see if you had any questions about Chance's proposed well maintenance work. I've re-attached our May 25th letter that was sent via email. As [redacted] mentioned below, we'd be more than happy to set up a conference call to provide a brief overview of the project and answer any questions you might have.
E00819	June 25, 2020	Email	In	First Nation of Na-cho Nyäk Dun	[redacted]	[redacted]	[redacted]	Engagement/Consultation DO Project	Email read receipt
E00710	July 13, 2020	Email	Out	First Nation of Na-cho Nyäk Dun	[redacted]	[redacted]	[redacted]	Engagement Reports/OIC Requirements	Hemmera has prepared a draft report on implementation of FNNND and Chance Engagement and Communication Plan for FNNND and Chance to review. This report summarizes meetings/correspondance that have occurred between FNNND and Chance since completing the 2019 Annual Report. I have attached the draft as a Word Document, if both FNNND and Chance could make revisions to that document in tracked changes, that would assist me in creating a final version. If there are any issues that arise between parties' revistion, we can address them via e-mail or a quick call. Once revisions have been incorporated and the document is considered final by FNNND and Chance, I will send the final version to both parties to sign. I have also attached, as a pdf, a draft of FNNND and Chance's Engagement Log which functions as Appendix D for the report. Please complete reveiws by Friday, July 24th. Reminder that reports need to be signed and submitted to YG on July 31st.
E00741	July 14, 2020	Email	Out	First Nation of Na-cho Nyäk Dun	[redacted]	[redacted]	[redacted]	Engagement Reports/OIC Requirements	I'm noticing a discrepancy between an email address we used to have on file for you and one that I've received some read receipts from recently (and that's also on the FNNND website). Is this your correct address? If I don't hear from you today/tomorrow, I'll give you a call to confirm.
E00767	July 20, 2020	Email	Out	First Nation of Na-cho Nyäk Dun	[redacted]	[redacted]	[redacted]	Engagement/Consultation DO Project	Chance Oil and Gas (Chance) is nearing completion of its proposal for well maintenance in the Eagle Plains and hopes to submit to the Yukon Socio-Economic and Environmental Assessment Board within the next two weeks. Chance and Hemmera provided an introductory letter, project summary, and map via email on May 25, 2020 and again on June 24, 2020. Our original correspondence was to Chief [redacted]. However, I may have used an outdated emails address for [redacted] so I've included an updated address as well as the previous one. We value any feedback First Nation of Na-cho Nyäk Dun may have with respect to this proposed project and look forward to working with you during the assessment process.
E00742	July 24, 2020	Email	Out	First Nation of Na-cho Nyäk Dun	[redacted]	[redacted]	[redacted]	Engagement Reports/OIC Requirements	I wanted to check in and see how your review of the draft engagement report was going? My apologies for not doing this sooner in the week. Despite my typo below, these reports are due to Yukon Government July 31, 2020. Not 2019, there is no time travel involved.
E00766	July 24, 2020	Email	Out	First Nation of Na-cho Nyäk Dun	[redacted]	[redacted]	[redacted]	Engagement/Consultation DO Project	Attached is a draft copy of Chance Oil and Gas (Chance)'s YESAB Project Proposal for the Eagle Plains Well Maintenance Project. In order for Chance to get all its approvals in hand before thw winter season, Chance's application will need to be submitted very shortly after sending this draft to you. At this time, our goal is to submit the Project Proposal middle of next week. As this document has not gone through Hemmera's formatting procedure, it is absent some of the figures and appendices. However, I've attached the Spill Response Plan which will be Appendix B. Chance continues to be committed to engaging with the First Nation of Na-cho Nyäk Dun. Should you wish to discuss the proposed Project in more detail, please don't hesitate to contact Chance or Hemmera.

E00744	August 3, 2020	Email	In	First Nation of Na-cho Nyäk Dun YG	[redacted]	[redacted]	[redacted]	Engagement Reports/OIC Requirements	We will be reaching out for a potential meeting update with you upon my return after August 18th, 2020.
E00775	August 7, 2020	Email	Out	First Nation of Na-cho Nyäk Dun	[redacted]	[redacted]	[redacted]	DO Project Engagement/Consultation	This email is intended to give you early notice that Chance Oil and Gas has not yet submitted our Well Maintenance Program Project Proposal to YESAB due to evolving discussions with the regulator. The amendments are being incorporated into the Project Description and effects assessment over the next week or two as we manage vacation absences. Once updated, we will share the updated YESAB submission with you to review. I suggest that a follow up conference call or Microsoft Teams meeting be arranged to address your questions or respond to your comments to the amendments.
E00999	August 21, 2020	Email	In	First Nation of Na-cho Nyäk Dun	[redacted]	[redacted]	[redacted]	DO Project Project Description/Activities	Email read receipt

E00909	August 28, 2020	Email	Out	First Nation of Na-cho Nyäk Dun	[redacted]	[redacted]	[redacted]	DO Project Project Description/Activities	Further to Richard's email dated August 7th (attached), Chance Oil and Gas (Chance) has made a few revisions to their Project Description for the Designated Office Evaluation of their proposed Well Maintenance Program. As a result of those changes, Hemmera has also revised the effects assessment sections of the Project Proposal. Below are the reasons for the revision that have been provided to us by Chance and a brief summary of the amendment itself: 1.Ongoing conversations between Chance and Yukon Government, Oil and Gas Branch (YG) have necessitated changes. While Chance was previously of the impression wells could continue to be suspended, YG is now directing Chance to conduct inspection and maintenance activities for all eight suspended wells and then abandon those wells or bring them into active status (i.e., end the period of well suspension). Chance is now proposing to abandon six wells (i.e., M-59, M-08, J-19, G-08, B-73, and H, 28) and to bring the remaining two wells (i.e., A-25 and E-78) into active status as deep-injection wells. Waste fluid produced during the abandonment of the six wells can then be disposed of via injection into the deep-injection wells. No oil or gas is expected to be produced from the two wells proposed to be activated; they would specifically be used for disposal of waste fluid from activities associated with these maintenance activities. (See sections 2.1.4 and 2.1.5 for further description) 2.At this time, Chance cannot confirm whether it will use the Eagle Plains Hotel or the existing Chance Camp for housing workers over the duration of the Project. The decision to utilize the Eagle Plains Hotel or the Chance Camp will be made when the Project schedule is finalized. It will also have to take into consideration the Hotel's ability to accommodate Chance workers over the full duration of the Project as well as COVID-19 related self-isolation requirements at that time. As a result both options are considered in the effects assessment for the housing of the project workforce. (See sections 2.2 and 2.3 for further description) 3.When the Chance field team were at Eagle Plain early August, they observed that the route used to access M-59 would require realignment of the final portion of Blackie Winter Road. The section of the original route that proceeds north for the final kilometer is not ideal for traffic due to steeper terrain. The steeper route would result in a significant risk to the trucks bearing heavy loads, fuel supply, and other fluid handling shipments. Chance is proposing shifting the final portion of Blackie Winter Road east of the original route in order to attain a much gentler gradient. (See section 2.1.1 and Figure 2-1 for further description) Each of the amendments above are described with additional detail within the attached revised Project Proposal. As previously, not all appendices are complete yet but will be
E00871	August 29, 2020	Email	In	First Nation of Na-cho Nyäk Dun	[redacted]	[redacted]	[redacted]	DO Project Engagement/Consultation	Email read receipt
E00903	September 15, 2020	Email	Out	First Nation of Na-cho Nyäk Dun	[redacted]	[redacted]	[redacted]	DO Project Engagement/Consultation Project Description/Activities	Since my email dated August 28th, Hemmera has been in the final stages of concluding the revised DO Project Proposal for Chance's Well Maintenance program. We have appreciated your feedback and worked to include that into the application. As you know, Chance's timeline for completing this work was tied to compliance with regulations, so in an effort to ensure that the maintenance activities could occur this winter Chance needed to submit the application last week. It was submitted late Friday evening and today Hemmera received confirmation that the project was on the YESAB registry. We acknowledge that you may have future comments on the project as it progresses through the YESAB process. We continue to look forward to hearing your views and are happy to hold additional meetings to discuss and answer any questions you may have. Please see the link to the registry here: Project 2020-0151 Eagle Plains Well Maintenance and Winter Activities
